LIST OF CONTRIBUTORS.

GENERAL EDITOR	W. T. BRANDE, D.C.L. F.R.S.L. & E. of Her Majesty's Mint, Hon. Prof. of Chemistry in the Royal Institution of Great Britain.
ASSISTANT EDITOR.	{ The Rev. GEORGE W. COX, M.A. late Scholar of Trin. Coll. Oxford.
Agriculture	{ JOHN CHALMERS MORTON, Editor of the 'Agricultural Gazette,' &c.
Architecture and General Literature	{ The Rev. GEORGE W. COX, M.A.
Astronomy, Observational and Descriptive, and Meteorology	{ E. FRANKLAND, Ph.D. F.R.S. Professor of Chemistry in the Royal Institution of Great Britain; and J. N. LOCKYER, Esq.
Biological Sciences, comprising Anatomy, Physiology, Zoology, and Palaeontology	Prof. RICHARD OWEN, F.R.S. LL.D. D.C.L. Superintendent of the Nat. Hist. Departments, British Museum; and C. CARTER BLAKE, F.G.S. For. Assoc. of the Anthropolog. Soc. of Paris.
Botany and Gardening	{ JOHN LINDLEY, M.D. F.R.S. F.L.S. Emeritus Prof. of Botany in Univ. Coll. London; and THOMAS MOORE, F.L.S. Curator of the Botanic Garden, Chelsea.
Building and Engineering	{ G. R. BURNELL, Architect and Civil Engineer, F.R.I.B.A. F.G.S. F.S.A.
General Chemistry and Physics	{ W. T. BRANDE, D.C.L. F.R.S.L. & E.; E. FRANKLAND, Ph.D. F.R.S.; and JOHN ATTFIELD, Ph.D. F.C.S. Director of the Laboratories of the Pharmaceutical Soc. of Great Britain.
Geology, Physical Geography, and Hydrology	{ D. T. ANSTED, M.A. F.R.S. F.G.S. &c. Hon. Fell. of King's Coll. London.
Law and General Literature	{ HERMAN MERIVALE, M.A. C.B. late Fell. of Balliol Coll. Oxford.
Mathematics, Pure and Applied	T. A. HIRST, Ph.D. F.R.S.
Military Subjects	{ Lieut. HENRY BRACKENBURY, R.A. F.S.A. Assistant-Instructor in Artillery, Royal Military Academy, Woolwich.
Mineralogy	{ HENRY WILLIAM BRISTOW, F.R.S. F.G.S. Hon. Fell. of King's Coll. London; of the Geolog. Survey of Great Britain.
Music	Prof. W. POLK, F.R.S. Mus. Bac. Oxon.
Naval Subjects	DENHAM ROBINSON
Navigation	H. W. JEANS, F.R.A.S. Royal Naval Coll. Portsmouth.
Painting and the Fine Arts	{ RALPH N. WORMUM, Keeper and Secretary of the National Gallery.
Political Economy	{ JAMES E. THOROLD ROGERS, M.A. Prof. Polit. Econ. Oxford; Tooke Prof. of Economic Science and Statistics in King's Coll. London.
Printing, Bibliography, &c.	{ R. J. COURTNEY, Superintendent at Messrs. Spottiswoode & Co.'s Printing Office.
Theology and Ecclesiastical Literature	{ C. MERIVALE, B.D. Chaplain to the Speaker of the House of Commons.

DICTIONARY

OF

SCIENCE, LITERATURE, AND ART.

G

G. The seventh letter of the English alphabet, but the third in those of all the Oriental languages, and also of the Greek. The form of our G is borrowed from the Roman alphabet. G, in English, has two sounds; before *a*, *o*, and *u*, and occasionally before *i* and *e*, it is the medial letter of the guttural order; the other sound, which it possesses only before *e* and *i*, is one of the medials of the sibilant series. The guttural G is liable to a variety of changes in different dialects and languages.

G, as a Roman abbreviation, is used for *gratis*, *gens*, *gaudium*, &c. G.V. signifies *genio urbis*, G.L. *genio loci*, and G.P.R. *gloria populi Romani*. As a numeral, it denoted 400. On the French coins G indicates the city of Poitiers; and in chronology it is the seventh Dominical letter.

G. In Music, a note of the scale corresponding to the *sol* of the French and Italians.

Gabardine or **Gaberdine** (Span. *gabardina*). A coarse frock or dress, mentioned by Shakspeare in the *Tempest* and *Merchant of Venice*.

Gabbro (Fr. *gabbro*, the Italian name of a rock composed of Diabase and Felspar). A mineral found in a vein of titaniferous iron near Arendal, in Norway. It is a silicate of alumina, soda, and potash. It has also been termed *Fuscite* and *Compact Soapstone*.

Gabel (Fr. *gabelle*, said to be derived from the Teutonic word *geben*, *to give*). Any impost laid on commodities was originally thus termed in France: as, *gabelle de vin*, *de draps*, &c.; but the word acquired in the course of time the peculiar signification of a duty on salt, which is meant when the word *gabelle* is used simply. The gabel was first established in the early part of the fourteenth century, during the reign of Philip of Valois, and with a brief interruption of five years, from 1340 to 1345, continued to be levied down to the reign of Louis XVI., at which time the revenue which it produced was estimated at thirty-eight millions of francs.

Vol. II.

GADOLINITE

The distribution of this tax was most capricious and arbitrary; and it may safely be affirmed that the gabel was one of the greatest curses imposed on France previously to the Revolution.

Gabian Oil. A petroleum or mineral naphtha exuding from the strata at Gabian, a village in Languedoc.

Gabions (Fr.; Ital. *gabbione*). In Fortification, cylinders, open at both ends, made of twigs or bands of iron twisted round stakes. When filled with earth, they are used as a screen from the enemy's fire, and torevet parapets.

Gable (Ger. *giebel*). In Architecture, the vertical part of a wall at the end of a roof, from the level of the eaves to the summit.

Gadfy. [*ESTRUM*.]

Gadoids, **Gadoideæ** (Gr. *γάδος*, *cod*). A family of soft-finned fishes, which belong to the section *Subbrachians*, or those which have the ventral fins below or in advance of the pectorals, and of which the cod-fish (*Gadus morhua*, Linn.) may be regarded as the type.

The general character of the Gadoid family is as follows: Body moderately elongated, sub-compressed, and covered with soft and very numerous scales; head smooth; jaws and front of the vomer armed with pointed, unequal, moderate, or small teeth, disposed in several rows, like a rasp; gill-openings large, and with seven rays; most of the species with two or three dorsal and one or two anal fins; stomach strong and capacious; caecal appendages very numerous; air-bladder large, with strong pærietes, often dentated laterally. The greater number of the cod tribe inhabit the seas of cold or temperate latitudes; their flesh is white and well-flavoured; they are very prolific, and constitute the most important subject of fisheries. The great sand-bank of Newfoundland is the most famous of the cod fisheries. [*FISHERY*.]

Gadolinite. A silicate of yttria, found in Sweden, chiefly near Fahlun, and at Ytterby, near Stockholm, in imperfect green crystals, and

B

GADUS

in amorphous masses, embedded in a coarse-grained granite. It was named after the Russian chemist Gadolin, who discovered in it a new earth, yttria.

Gadus (Gr. γάδος). [GADIDS.]

Gadlie or **Gadhelie**. [ESSA.]

Gaff. The boom or yard extending the upper edge of what are called *fore* and *aft* sails. The gaff turns on the mast against which its thicker end rests; the mast, as an axis, occupying a semicircular cavity in the end of the gaff. This cavity is known as the *gaff's jaws*. It is supported by two independent ropes; the *throat halliards* at the mast, and the *peak halliards* at the outer end. It is steadied, when the sail is not set, by ropes at the extremity called *vangs*.

Gage or **Gauge** (Fr. jauge). In Architecture, the length of a slate, or tile, exposed beyond the lap; also the measure to which anything is confined. Plasterers use the word to signify the greater or less quantity of plaster of Paris used with the common lime and hair to accelerate the setting; bricklayers use it to express the state of mortar: thus, they say a mortar is gaged stiff, or thin, as it partakes of one or other of those qualities. Engineers use the word to express the distance between rails, the thickness of boiler plate, wire, copper, and other materials.

GAGE or **GUAGE**. In Physics, any apparatus for measuring pressure, force, height, depth or size. Thus the *gage* of an *air-pump* indicates the extent to which the rarefaction in the receiver has been carried. [AIR-PUMP.] The *steam gage* measures the pressure of steam in any vessel; the *wind gage*, the force of the wind; the *tide gage*, the height of the tide, &c. [ANEMOMETER; HYDROMETER.]

Gahnite. A native aluminate of zinc, called also *Automolite*. Named after Gahn, who first described it.

Gaillarde. The name of a lively dance peculiar to Italy, and supposed to have been practised by the ancient Romans, whence it is sometimes designated *Romanesque*.

Gainage. In old English writers, this word signifies the draught oxen, horses and their furniture, which were left free when a villein was amerced, that agriculture might not be interrupted.

Gaining Twist. In rifled arms, a twist or spiral inclination of the grooves, which becomes more rapid towards the muzzle.

Galactic Circle (Gr. γαλακτικός, *milky*). A term first used by Sir John Herschel to denote that great circle of the heavens to which the course of the Milky Way, as traced by the unaided eye, most nearly conforms. It is inclined, at an angle of about 63°, to the equator, and cuts that circle in two points, whose right ascensions are respectively about 0 h. 47 m. and 12 h. 47 m., so that its northern and southern poles respectively are situated in R.A. 12 h. 47 m., N.P.D. 63°, and R.A. 0 h. 47 m., N.P.D. 117°. This circle, Sir John Herschel observes, is to sidereal what the invariable

GALAXY

ecliptic is to planetary astronomy—a plane of ultimate reference, the ground-plane of the sidereal system. [GALAXY.]

Galactic Poles. The two opposite points of the heavens, situated at 90° from the Galactic Circle.

Galactine (Gr. γάλα, *milk*). An ingredient in the sap of the *Brosimum Galactodendron*, or Cow-tree of South America.

Galactite (Gr. γάλα). A fossil substance, not unlike French chalk. When immersed in water, it has the colour of milk.

Galactodendron (Gr. γάλα, *milk*; δένδρον, *a tree*). [BROSIMUM; COW-TREE; GALACTINE.]

Galactopoietic (Gr. γάλα, *milk*, and ποίω, *I make*). A term applied by some medical writers to diet and medicine supposed to promote the secretion of milk.

Galangal. A dried root brought from China; it has an aromatic smell, and a pungent bitter flavour, and was formerly used in medicine. The greater galangal is the produce of the *Kempferia Galanga*, and the lesser of the *Maranta Galanga*.

Galanthus (Gr. γάλα, *milk*, and άνθος, *a flower*). The Snowdrop genus, especially interesting in gardens as being the 'first pale blossom of the unripened year.' The common Snowdrop is *G. nivalis*; a larger and finer species, *G. plicata*, is a native of the Crimea.

Galatea. [ACIS.]

Galathea. A genus of long-tailed (macrourous) Crustacea, including some very beautiful species (*G. rugosa*, *strigosa* et *squamifera*), occasionally found on the British coasts. The true *Galathea* have the thorax oblong or ovoid, the median antennae produced, and the pincers elongated. This term is derived from the name of the nymph Galatea.

Galaxy (Gr. δ γαλαξίας κύκλος). The *Via Lactea* or Milky Way. This luminous zone, so remarkable in a clear night, must have attracted the notice of the first observers of the heavens, and its true nature seems to have been surmised at an early period. Manilius, in his *Astronomicon*, after alluding to the well-known mythological fable of its origin, asks—

Anne magis densas stellarum turba coronæ
Contextit flammis, et cernens lumine candet,
Et fulgore nitet collato clarior orbis?

The explanation of the phenomenon here suggested, namely, the condensed light of countless multitudes of small stars so crowded together as to be individually undistinguishable, is ascribed to Democritus, and its truth was confirmed, or at least rendered much more probable, immediately on the discovery of the telescope, Galileo himself enumerating among the advantages resulting from his instrument, that of putting an end to the disputes about the nature of the Milky Way. About the middle of the last century, Wright of Durham, and Kant and Lambert in Germany, speculated on the connection of the phenomenon with the general arrangement of the stars in space; but the first who undertook a systematic examination of the galaxy with telescopes of adequate power

GALAXY

was Sir William Herschel, and to the indefatigable labours of this great astronomer, and to those of Sir John F. W. Herschel (who, during his memorable residence at the Cape, with the same telescope which had been used by his father, and by a similar process of examination, explored those regions of the sky which are invisible in our latitudes), astronomers are mainly indebted for the facts upon which any sound speculation respecting the constitution of the heavens can as yet be founded.

The Milky Way, as seen by the naked eye, presents the appearance of a succession of luminous patches of varying intensity. Its breadth is very unequal, in some parts hardly exceeding 5° , in others extending to 16° ; and there is a part between Serpentarius and Antinous where the two branches into which it is there divided occupy together a breadth of 22° . Its course through the heavens is nearly that of a great circle inclined at an angle of about 63° to the equator, and cutting that circle in two points whose right ascensions are, respectively, 0 h. 47 m. and 12 h. 47 m. Struve remarks that the most condensed stratum does not lie exactly in one plane, but appears rather to be contained in two different planes inclined at an angle of 10° , and intersecting in the plane of the celestial equator, the sun being at a little distance from the line of intersection. This slight deviation from a great circle had been remarked at an earlier period, and Lambert supposed it might be occasioned by the place of the sun being not exactly in the middle of the zone, but a little on one side. It is convenient, however, in speaking generally of the system of the galaxy, to refer it to a great circle of the sphere; and the great circle to which it most nearly conforms has been named by Sir John Herschel the *Galactic Circle*.

At several parts of its course the Milky Way throws off streams or branches. In Perseus a branch is sent off which is traceable to a considerable distance. Another proceeds from a point near the star *m Puppis*, nearly on the southern tropic. In Argo it opens out into a wide fan-like expanse, nearly 20° in breadth, which terminates abruptly, and at this part its continuity is interrupted by a wide gap. At *α Centauri* it again subdivides. At *γ Sagittarii* it suddenly collects into a vivid oval mass, about 6° in length and 4° in breadth, so exceedingly rich in stars that a moderate calculation gives upwards of 100,000. On the other hand, spaces occur in the very middle of its course, which appear, to the naked eye, entirely devoid of stars, and perfectly black. The most remarkable of these is situated in the Southern Cross, where the Milky Way approaches the nearest to the south pole, and so striking is its appearance that the early navigators designated it by the name of the *coal sack*. This space is of an irregular pear-shaped form; it is about 8° in length and 5° in breadth; and was described and figured by the Abbé Feuillée in 1710. Lacaille correctly attributed its striking blackness to the effect

of contrast with the luminosity of the Milky Way, which surrounds it on all sides, and which in this region is remarkably brilliant.

It is to be remarked that the great increase in the number of stars which is observed in the neighbourhood of the galaxy is occasioned chiefly by the greater abundance of telescopic stars, that is to say, of those beyond the sixth order of magnitude. Stars of the first magnitude are distributed over the sphere with tolerable uniformity. If, however, we take the whole number visible to the naked eye, a rapid increase is perceptible as we approach the limits of the galaxy; but, with respect to those of the smaller magnitudes, and particularly beyond the eleventh, the accumulation along that circle and its branches almost exceeds imagination. The vast predominance of the small stars must be held to indicate the immense distances at which they are situated.

From the relatively greater abundance of stars in the plane of the Galactic Circle than in the regions on either side of it, and from the indication of some preponderance on the southern side, Sir W. Herschel drew the conclusion that the galaxy is composed of a stratum of stars of which the thickness is inconsiderable in comparison with its length and breadth, and that the sun is placed not far from the middle of the stratum, somewhat nearer to its northern than to its southern surface, and near the point where it subdivides into two principal laminae inclined at a small angle to each other. Assuming the real magnitudes of stars to be the same, on the average, through the whole sidereal system, he determined by a series of photometrical experiments that stars of the sixth magnitude (the least visible to the naked eye) are twelve times more remote than those of the first, and that the penetrating power of his twenty-foot telescope was seventy-five times greater than that of the naked eye, so that the smallest stars visible in the telescope are at a distance equal to 900 times the distance of Sirius. Now, as the average apparent breadth of the Milky Way is about 5° , its thickness at that great distance must be $900 \times \sin 5^\circ$, or equal to seventy-eight times the distance of Sirius, or more than six times the distance of the stars of the sixth magnitude. Therefore the Milky Way, even in the direction of its poles, extends to three times the distance of the smallest stars visible to the unaided eye, the sun being supposed at the centre of the stratum. Hence it follows that not only our solar system, but all the stars in the firmament visible to the naked eye, are plunged to a great depth in the stratum of stars composing the galaxy, and form an integral part of it.

It must be kept in mind that the above conclusions are based on two hypotheses which are, at best, very precarious; and in fact both of them appear to have been abandoned by Sir W. Herschel himself in his later years. With respect to the first, namely, the distribution of the stars in space at nearly equal distances from each other, he remarks, in a paper pub-

GALAXY

lished in 1817, that although a greater number of stars in the field of view may be taken in general as an indication of their extension to a greater distance, yet the gauges have in reality more direct reference to the condensation than to the distance, and hence a greater number in the field of view may be explained as well by a greater condensation of the galaxy as by a greater extension of its figure in the direction in which the stars appear most numerous. The other hypothesis, namely, that the telescope penetrates to the extreme boundaries of the galaxy, is subject to much doubt. Sir W. Herschel, speaking in 1818 of his forty-foot telescope, the penetrating power of which he estimated to reach to 2,300 times the distance of Sirius, states, as his opinion, that even at this enormous distance the limit of the stratum was not attained, inasmuch as the telescope failed to resolve the nebulous appearance into stars, and he therefore concluded the stratum to be fathomless. Sir John Herschel thinks the limit has been attained only in certain directions: 'Throughout by far the largest portion of the extent of the Milky Way in both hemispheres, the general blackness of the ground of the heavens on which its stars are projected, and the absence of that innumerable multitude and excessive crowding of the smallest visible magnitudes, and of the glare produced by the aggregate of multitudes too small to affect the eye singly, which the contrary supposition would appear to necessitate, must, we think, be considered unequivocal indications that its dimensions, in directions where these conditions obtain, are not only not infinite, but that the space-penetrating power of our telescopes suffices fairly to pierce through it and beyond it.' But, on the other hand, there are parts where not the slightest indication of a limit is discernible. 'Such is, in effect, the spectacle afforded by a very large portion of the Milky Way in that interesting region near the point of its bifurcation in Scorpio, where, through the hollows and deep recesses of its complicated structure, we behold what has all the appearance of a wide and indefinitely prolonged area, strewed over with discontinuous masses and clouds of stars, which the telescope at last refuses to analyse.'

There is also another objection which has been raised by Struve, namely that the celestial spaces are not perfectly transparent, and that therefore the light of distant stars is enfeebled more than in proportion to their distance.

The only conclusions which can be safely drawn are the following:—

1. That the whole light of the Milky Way is nothing but the light of innumerable stars of all magnitudes down to the faintest point perceptible in the best telescopes.

2. That the phenomena, on the whole, agree with the supposition that the stars of our firmament, instead of being scattered through space indifferently in all directions, form a stratum of which the thickness is small in comparison with its length and breadth, and that the sun occupies a place near the middle of the

GALENA

thickness, and near the point where the stratum is subdivided into two principal laminae.

3. That if all the fixed stars in the firmament be regarded as forming one great system—that of the galaxy—we are still in complete ignorance of its extent, and without the least idea of what may be called its ground plan.

Galbanum (Lat.; Gr. χαλβάνη). A slightly fetid gum resin, produced by the *Galbanum officinale*. It is imported from Turkey and the East Indies for medical use, but is of little importance.

Galbula (Lat. *the yellow bird*). A genus of Scansorial birds closely allied to the kingfishers by their elongated sharp-pointed beak, the upper ridge of which is angular; and by their short feet, the anterior toes of which are almost wholly united: these toes, however, are not precisely the same as those of the kingfishers. The plumage of the species of *Galbula* which are called by the French *jacamars*, is not so smooth as that of the kingfishers, and always has a metallic lustre. They are solitary birds, that live in wet forests, feed on insects, and build on low bushes.

Galbulus. In Botany, a term invented by Gärtner, to denote a form of fruit similar to a cone, excepting that the galbulus is round, and has the heads of the carpels much enlarged, as in the fruit of the juniper.

Gale. The *Myrica Gale*, a small native fragrant bush, of the order *Myricaceæ*, found in boggy places.

Gale of Wind. The Sea term for a continued storm of wind: the lowest degree is the *fresh gale*, the next a *strong gale*, and the last a *heavy or hard gale*, called also a *whole gale*.

Galea (Lat.). In Antiquity, the head-piece or helmet used in battle by the Roman soldiers. The *gala* was used for the same defensive purposes as the *cassis*; but differed from it in this, that while the *cassis* was the term properly applied to helmets made of *nutal*, the *galea* was originally of *hides*.

GALEA (Lat.). In Botany, the helmet or arched part of a flower, as seen in the Acouite; hence *galate*, helmeted.

Galega (Gr. γάλα, because it is supposed to increase the milk of animals, especially of goats). The name of a genus of plants, including *G. officinalis*, or Gont's Rue, a plant of little taste, and eaten in Italy in salads. It was formerly held in some repute as a cordial in fevers. The genus consists of perennial herbs of the Leguminous family, nearly related to *Glycyrrhiza*.

Galena (Lat.). Native sulphide of lead, composed, when pure, of 86·6 per cent. of lead and 13·4 sulphur. It forms bunches and veins in igneous and sedimentary rocks, especially in Carboniferous Limestone, in which it often fills irregular cavities and fissures. It occurs in amorphous masses with a lamellar structure, frequently granular, especially when silver is present, sometimes almost compact, and crystallised in cubes, octahedrons, or their modifications. The colour is lead-grey, much like

GALENISTS

that of the metal lead, with a metallic lustre, and sometimes superficially covered with an iridescent tarnish. Galena is the most abundant ore of lead, and that from which the greater part of the metal is obtained.

Sometimes Galena is so rich in silver as to be worked almost entirely as an ore of that metal, as is the case at the mines of Saxony, the Harz, and those of Bleyberg in the Eifel.

The largest lead mine in the world is that of Allenheads in Northumberland; and some of the purest metal is that produced at the Austrian mines of Nötsch in Carinthia.

Galenists. In Ecclesiastical History, a subdivision of the sect called Waterlandians in the seventeenth century. In Medical History, the followers of Galen were so termed, in opposition to the practitioners of the chemical school.

Galeopithecus (Gr. γαλή, a weasel; πίθηκος, an ape). A genus of Insectivorous Mammalia, having the bones of the arm and leg, but not those of the digits, excessively elongated, and supporting extensive lateral folds of skin which are useful as a parachute, but not as organs of flight. The species are restricted to the great islands of the Indian Archipelago; their inferior incisors are remarkable for their complex form like the teeth of a comb.

Galeruca (Lat. galerus, a cap or tuft). A genus of Tetramerous Coleoptera, now the type of an extensive family (*Galerucidae*), including amongst other subgenera the noxious turnip-flies (*Haltica*). All the *Galerucidae* are vegetable feeders, both in their larva and in their perfect state. There are about a dozen known British species of *Galeruca* proper, which are small, and generally dark or dull-coloured beetles.

Gallacææ (Galium, one of the genera). A natural order of herbaceous Exogens of the Cinchonalliance, inhabiting the cooler parts of the world. They are distinguished from *Cinchonacææ* by their square stems and verticillate leaves without stipules. The roots of *Rubia tinctoria* yield Madder, and those of *R. cordifolia* furnish the Munjeet dye of India.

Galpea (the Guiana name). The genus of *Rutacææ* yields the Angostura Bark of the Pharmacopœia. It is said to be produced both by *G. officinalis* and *G. cusparia*, and hence is sometimes called Cusparia Bark. It is employed in medical practice as a tonic, and by the natives of Guiana to stupefy fish.

Galipot. A white resin derived from the *Pinus maritima*.

Galium (Gr. γάλα, milk). A genus of scrambling herba, with stellately whorled leaves, small flowers often inconspicuous, and fruits consisting of two dry seed-vessels, each containing a single seed. *G. Aparine*, the Cleavers or Goosegrass, is a common weed in almost every hedgebank, and is remarkable for its globular fruits being covered with hooked prickles. The torrefied seeds are said to be a good substitute for coffee, and the flowers of *Galium verum* are used to curdle milk. The roots of some of

GALLERY

them afford a purple dye. Like Madder, they belong to the order *Galiacææ*.

Gall (Gr. γαλή). [BIZA.]

Gall of Glass. The salts and other impurities which float upon the fused materials for the manufacture of glass, and which are skimmed off. They are also called *sandiver*.

Gall Insects. The name of a family of Hemipterans, comprehending those of which the females, towards the period of oviposition, assume a globular form, analogous to the galls caused by the *gallincolæ*.

Gall Nuts. Excrescences produced by the *cynips*, a small insect which deposits its eggs in the tender shoots of the *Quercus infectoria*, a species of oak abundant in Asia Minor. When the maggot is hatched, it produces a morbid excrescence of the surrounding parts, and ultimately eats its way out of the nidus thus formed. The best galls are imported from Aleppo and Smyrna; their principal ingredients are tan and gallic acid. The infusion of galls affords a dense white precipitate in solution of gelatine, and a black precipitate with the persalts of iron. The latter property leads to the use of galls in the manufacture of ink and of black dye; they are also used as an astringent in medicine.

Galls. Local affections or diseases of plants, caused by the puncture of insects. They are produced by an excessive deposition of cellular tissue, and are of no consequence to the general health of the individual subject to them.

Gall-bladder. An oblong membranous receptacle attached to the under part of the liver. It retains the bile which regurgitates from the hepatic duct, and sends it through the cystic duct, which proceeds from its neck into the *ductus communis choledochus*, and thence into the duodenum.

Gall-stones. Concretions occasionally found in the gall-bladder and biliary ducts. They consist either of a peculiar fatty matter called *cholestrine*, or of inspissated bile, or of mixtures of the two. The gall-stones of the ox generally contain a peculiar yellow colouring matter which is valued by painters.

Galleon (Ital. galeone). A name formerly applied to large and lofty ships of war: it was subsequently limited to the treasure ships which brought the riches of the New World to Spain. They were heavy unmanageable vessels.

Gallery (Ital. galleria, Fr. galerie). In the Fine Arts, a term applied to a collection of works in painting or sculpture, or to the building containing it. The earliest gallery or museum of which there is any record was that of the Heræum or temple of Juno at Samos, to which a picture gallery (πικασθήκη) was attached. The Pæcile, or painted chamber, at Athens was a gallery of paintings, but not quite in the sense now applied. The Egyptian Ptolemies formed collections of pictures, as did also the Romans: Verres had a remarkable collection of works of art; and most of the public temples of Rome were depositories of works of painting and sculpture; the Temple of Peace

GALLERY

was renowned for its collections. Constantinople, however, had still greater accumulations than Rome. In Europe, the magnificent Museum of the Louvre, though much reduced in 1815 by the restoration of many works acquired by conquest, is still one of the richest in pictures numerically; but it does not possess so many first-rate Italian pictures as the British National Gallery. The gallery founded at Florence by Cosmo II. long enjoyed the first rank, but must be now considered secondary to several European galleries. The treasures of Florence are, however, divided into two collections—that of the Uffizi, and that of the Pitti palace; but both galleries combined do not equal in numbers the collections of Dresden, of Madrid, or of the Louvre. Numbers, of course, are not the real test of the value of a gallery of works of art; but where all have been formed with more or less indiscriminate, it becomes a fair test. The selected galleries are few, those of the Vatican at Rome, the National Gallery in London, and the Pinacothek at Munich being almost the only examples. If we rank the principal galleries of Europe according to their numbers, the following is their order at this date (1865): 1. Versailles, about 3,300 works, chiefly French battles; 2. Dresden, about 2,200 pictures; 3. Madrid, Real Museo of the Prado, 1,833; 4. The Museum of the Louvre, about 1,800; 5. The Hermitage at St. Petersburg, 1,631; 6. The Gallery of Berlin, 1,250; 7. The Belvedere at Vienna, upwards of 1,550; 8. The Pinacothek of Munich, 1,270; 9. The Gallery of the Uffizi at Florence, upwards of 1,200; 10. The National Gallery, London, about 750; 11. The Gallery of the Museo Borbonico at Naples, about 700; 12. The Academy at Venice, 686; 13. The Academy of Antwerp, 584; 14. The Gallery of Turin, 569; 15. The Brera of Milan, 503; 16. The Pitti Palace, Florence, 500; 17. The collection of Brussels, 400; 18. The Gallery of Amsterdam, 386; 19. The Städel Institution at Frankfurt, 380; 20. The Museum at the Hague, 304; 21. The collection of the Academy of Bologna, 280; 22. The Capitol at Rome, 225; and 23. The celebrated Gallery of the Vatican at Rome, only 37. The National Gallery of London is unfortunately at present divided, from utter insufficiency of space at Trafalgar Square, a part of the national collection being placed at Kensington; if united in one whole and properly displayed, it would appear what it is, not only one of the most select and valuable, but also one of the larger European galleries; and it is yet only in its infancy: it was first opened to the public on May 10, 1824, with 38 pictures, just one more than the Vatican possesses at this day. Edinburgh and Dublin have also now their national galleries, and England possesses also the public collections at Hampton Court and Dulwich, besides the valuable royal gallery at Windsor, and the private galleries of the duke of Sutherland, the marquis of Westminster, the earl of Ellesmere, and others. The Borghese Gallery, a collection of upwards of 500 valuable

GALLEY

pictures, and the Esterhazy and Lichtenstein collections at Vienna, are perhaps the best private galleries. The Vatican at Rome and the British Museum possess the largest and most valuable galleries of sculpture.

GALLERY. In Fortification, a covered passage, sometimes constructed under the counter-scarp and loop-holed.

GALLERY. In Mining, a passage leading inwards from the entrance of the mine.

Galley (Fr. *galère*). A low-built vessel propelled by sails and oars, either on a single tier, or on tiers of benches one above the other. The war vessels of antiquity were all galleys. Among the Greeks those chiefly mentioned are the pentecontori, which appear to have had fifty oars disposed in a single tier; and the triremes, vessels with three banks of oars. [THURME.]

Galleys were likewise employed by the maritime nations of the middle ages in the Mediterranean. Their use in naval war hardly ceased until the end of the seventeenth century; and the Venetian republic, down to the period of its extinction, always maintained a number of war galleys. The Venetian galleys had a single tier only, and all modern galleys followed the same construction. These were formidable vessels in a calm, but unfit for a rough sea. The Venetians had also a large high-pooped sort of galley called *galeazza*, whence the word *galleass* and *galliot* in old English writers.

The name *galley* is also applied to some of the smarter boats of a ship of war, as the *admiral's galley*, the *captain's galley*. The latter is a handsome and very swift boat, propelled by six alternate oars, handled by a picked crew. The *galley* in a ship is the place where cooking is carried on: it is in the forepart of the vessel, on one of the lower decks.

The punishment of the *galleys*, i.e. the employment of condemned criminals in the toilsome employment of rowing them, is said to have originated under the Greek empire. It was used by all the nations bordering on the Mediterranean. In France, under the old jurisprudence, the punishment of the galleys was the severest of secondary penalties. About the end of the reign of Louis XIV., when galleys themselves began to be disused, the galley slaves were employed in hospitals, public works, &c.; and the name of the punishment was changed by the Constituent Assembly (1793) to *travaux forcés*, compulsory labour, whence the word *forçat* for a criminal so condemned. Under the code of the empire the punishment was accompanied with forfeiture of property, infamy, and branding. By an attenuation of the law effected in 1832, the brand was abolished; and the criminals, who had hitherto been intermingled in the three penal fortresses (Toulon, Rochefort, and Brest), were classified. Toulon was appropriated to those condemned for ten years and under; Brest, to those from ten to twenty; Rochefort, to persons condemned for life. The name *bagne*, applied in France to prisons in which those condemned to compulsory labour are confined,

is derived from the famous Bagnio prison at Constantinople, so called on account of some baths situated there. The principal crimes now punished in this manner by the French law are—some acts of violence against the government or public law; coining or forgery; assaults followed by death on legal officers; murder, unless under aggravated circumstances; rape, abduction, burglary, highway robbery, perjury, &c.

GALLERY. In Printing, pieces of thin board or metal of different sizes, with ledges about three-fifths of the height of types, for receiving the matter as it is composed, and for affording a level on which to make it up into pages.

Gall. In Roman Antiquities, priests of Cybele, at Rome. The origin of the word is uncertain, but they are said to have been so called from the river Gallus in Phrygia, whence the worship of the goddess was introduced into Rome B. C. 204. (Liv. xxix. 14.) These priests were always eunuchs (Lucretius ii.); and being chosen from a low class, were, unlike all other priests, allowed to beg on certain days. (Cic. *De Legibus* ii. 9.) In their rites they resembled the *CORYBANTES*, *DACTYLI* and *CURÆTES* [which see].

Gallie Acid. An acid obtained from galls and some other vegetable astringents. It is white, crystalline, and soluble in water and alcohol. It gives an inky-blue colour with a persalt of iron, but no precipitate with gelatine, which distinguishes it from tannic acid. When heated to about 415°, it is resolved into carbonic acid and *pyrogallie acid*; this latter acid is largely manufactured for the purposes of photography.

Gallican Church. The distinctive title of the Roman Catholic church in France, which maintains a certain degree of independence in respect of the Roman see. The liberties of the Gallican Church, first asserted in the Pragmatic Sanction (1438), were defined and confirmed in the Quatuor Propositiones Cleri Gallicani, promulgated in 1682. The occasion of this declaration was a dispute between Louis XIV. and Pope Innocent XI. concerning the right long practised by the French kings of occupying in their own persons the inferior preferments of a diocese which lapsed during the vacancy of the see. It was then determined by an assembly of the French clergy, that the pope has no temporal, but only spiritual rights, as the viceroy of Christ: that even these are limited by canons and councils: and that the decrees of the holy see are subject to reversal upon the decision of the clergy in general. (*Declaration of the French Clergy concerning Ecclesiastical Power*, drawn up by the famous Bossuet, bishop of Meaux, in the assembly convoked by Louis XIV. in 1682.) While, however, it asserts this liberty in speculative points, the Gallican church does not differ from the Roman in any points of faith. It has, however, always been the object of the Jesuits, and that large party, both of clergy and laity, who have sided with them, to bring the church in

France more closely into submission to the see of Rome. The Jansenists; the great legal body, headed by the parliaments; and many of the leading divines of that church, such as Fleury and Bossuet, were arrayed on the other side: and the struggle continued with more or less vehemence through the eighteenth century. The suppression of the Jesuits appeared for the time to give the victory to the Gallican side. But it may be said to have suffered, in the eyes of the Catholic public in general, a very severe defeat when, in the early part of the Revolution, its leaders sided to a considerable extent with the party of progress, and accepted the 'civil constitution' of the clergy. The period of lowest external power of the church in France was that of the revival of what are commonly called Ultramontane opinions in the church of Rome; those, namely, which exalt most highly the papal power, and are most opposed to the existence of anything approaching to national and independent churches or branches of the church within the communion of Rome. Accordingly, the concordat effected by Napoleon I. with Rome, although it established a church, in the political sense of the word, dependent on the State, yet in no degree tended to reconstitute that Gallican church which the great divines of the age of Louis XIV. had endeavoured, with some success, to build up. Since that time the Ultramontane school appears to have acquired still more decided influence among the clergy of France.

Gallism. Literally, a phrase or construction peculiar to the French language, but used generally to denote such phrases or modes of speech in English as are formed after the French idiom.

Galliolela (Lat. *galla*, a gall; *colo*, I inhabit). The name of a family of Pupiparous Hymenoptera, including those of which the larvae inhabit the galls or vegetable excrescences caused by the perforation and oviposition of the parent insect.

Gallinaceans, Gallinacea (Lat. *gallus*, a cock). [RASONIA.]

Gallinule or Water-hen. The type of the subgenus *Gallinula*, now dismembered from the *Fulica* of Linnaeus, which term is restricted in modern systems of ornithology to the Coots proper.

Galliot. A strong and cumbrous bluff-bowed vessel used by the Dutch, having a main mast and a mizen mast, usually close aft.

Galliotenite. A mineralogical synonym of *Titanite*.

Gallon (Old Fr. *galon*). An English measure of capacity. By Act of Parliament the imperial gallon is to contain 10 lbs. avoirdupois of distilled water, weighed at the temperature of 62° of Fahrenheit, the barometer standing at 30 inches. This is equivalent to 277.274 cubic inches. The old English gallon, wine measure, contained 231 cubic inches; beer measure, 282 cubic inches. [MEASURE.]

Gallotannic Acid. The tannic acid, or astringent principle of nut-galls, obtained on

GALLOWSBITS

percolating galls with washed ether and evaporating the aqueous portion of the percolate. It forms an insoluble compound with gelatine, the formation of which is the chief feature in the operation of *tanning* hides to form leather. Its combination with iron forms the basis of black writing inks. [TANNIN.]

Gallowbits. On Shipboard, consist of a stout wooden framework for the support of spare spars.

Gally-worm. [JULIS.]

Galt. [GAULT.]

Galvanism (from Galvani, professor of anatomy at Bologna, the discoverer of some of the phenomena connected with this form of electricity in the year 1790). Under this term are frequently included the phenomena of VOLTAIC ELECTRICITY [which see]. We shall here limit it to the apparent evolution of electricity by the contact of different metals; this is best observed by the muscular contractions which are produced in the leg of a frog recently killed, when two different metals, such as zinc and silver, tin and gold, &c., one of which touches the crural nerve, and the other the muscles, are brought into contact. Every time the metals touch each other, the limb becomes powerfully convulsed; and if the experiment be made with a dead rabbit, one of the metals being in contact with the brain, and the other with the muscles of the extremities, the whole body of the animal is strangely agitated. Similar experiments have been made upon the bodies of criminals shortly after execution. These results, which have till lately been considered to depend upon the effects of electricity excited by the contact of the metals upon the nervous and muscular systems, led Volta to his celebrated researches, which terminated in the discovery of the *Voltaic battery*. Nearly all the cases, however, of the apparent production of electricity by contact have been satisfactorily traced by Faraday to chemical action. [VOLTAIC BATTERY.]

Galvanometer. An instrument for ascertaining the presence and estimating the amount of a current of electricity, especially galvanic or voltaic electricity, by the deviation which it occasions in the magnetic needle. The simplest form of galvanometer is a magnetic needle poised upon a point, and surrounded by one or more coils of copper wire covered with silk, the ends *a* and *b* either being left free, or terminating in two small copper cups containing mercury, for the convenience of communication with the source of electricity. When this needle is placed parallel to the coil, and in the magnetic meridian (as represented in the above figure), it immediately deviates when the electric current passes through the coil; and the deviation is either to the east or the west, according to the direction of the current. [ELECTRO-MAGNETISM.]

Sometimes the needle is surrounded by two separate coils of wire, through which two

GAME LAWS

electric currents can be made to pass in different directions; the deflection of the needle then indicates the comparative strength of the two currents which are tending to deflect it in opposite directions. Such an instrument is termed a *differential galvanometer*. Recently a very sensitive galvanometer has been devised by Prof. William Thompson: it has a small mirror attached vertically to the axis, and upon this mirror a beam of light is thrown, which being received upon a screen at the distance of several feet from the instrument, magnifies any deflection of the needle enormously; since the beam reflected from the mirror not only acts like an arm of the same length, but also travels with twice the angular velocity of the mirror. This form of instrument is termed a *reflecting galvanometer*.

Galvanoscope. An instrument for detecting slight currents of electricity. Its construction is the same as that of the galvanometer; but, being merely a qualitative instrument, it has no provision for measuring the angle of deflection of its magnetic needle. [GALVANOMETER.]

Gamba (Lut.). A technical term in Mammalogy, applied by Illiger to the elongated *metatarsus* of the Ruminants and Solipeds.

Gambeson. [POWERS.]

Gambir. An astringent drug obtained from *Uncaria Gambir*, and used as a substitute for Catechu.

Gamboge. A yellow gum resin much used as a pigment, and in medicine as a drastic and nauseating purge. That which is imported from Ceylon in cakes rolled up in flag leaves, is the produce of the *Garcinia Cambogia*. That of Mysore is said to be the produce of *G. pictoria*; while that of Siam has been ascertained to come from a variety of *G. Morella*.

Game Laws. The principal statutes relating to game now in force, are the 7 & 8 Geo. IV. c. 49, the 9 Geo. IV. c. 69, and 1 & 2 Wm. IV. c. 32, with several subsequent statutes amending these enactments. By the common law, which followed the old forest law, as introduced into this country by the Normans, all game was the property of the king; no person whatsoever could enjoy the diversion of sporting, unless authorised by royal grant of a chase or free warren; and to kill a deer was deemed almost as heinous an act as to kill a man. But although at common law no persons could with impunity encroach upon the kingly prerogative of pursuing game, yet those were exposed to the additional pains and penalties of the statute law who committed this offence not being possessed of a certain rank or dignity, or of a certain amount of landed property. Strictly speaking, then, the superior condition in life of a party constituted the ground of his exemption from additional punishment, and not, as commonly supposed, a qualification to do that which was altogether interdicted, whether to the peer or the peasant. But the aggravated offence under the statutes, namely, that of sporting without rank or fortune, being in later times severely

GAMES

visited, while the original offence at common law was passed over, rank and fortune were, in the end, looked upon as a qualification; and a freehold estate of 100*l.* a year, or leasehold for 99 years of 150*l.* a year, or being the son and heir apparent of an esquire or person of superior degree, were accounted as so many qualifications. The statute law prohibited any persons whatsoever, whether qualified to kill game or not, from making it the subject of sale or merchandise.

The principal alterations in the law made by the last Act, above mentioned are, first, that all qualifications are done away with, and that any person taking out a proper certificate may kill game on his own land, or that of another person, with his leave; and secondly, that every person having such a certificate may sell game to any person licensed to deal in it according to the Act, who again is at liberty to retail it without restriction.

Most trespasses and offences relating to game are punishable upon summary conviction, before magistrates. The most serious of these offences is what is called *night poaching*. After two convictions before a magistrate for this offence it becomes a misdemeanour, to be proceeded against by indictment and punishable by penal servitude for seven years, or imprisonment and hard labour. Night poaching committed by three or more persons in company together is a misdemeanour in the first instance, and punishable by penal servitude for fourteen years, or imprisonment and hard labour. By the last Act for the Prevention of Poaching, 25 & 26 Vict. c. 114 (1862), power is given to constables to search for game, without warrant in certain cases, and to detain the game, the party who is found to have unlawfully taken it being liable to fine. For the purposes of this Act, the word *game* is defined to include hares, pheasants, partridges, woodcocks, snipes, rabbits, grouse, black or moor game; besides the eggs of several of these birds.

Games (A.-Sax. *gaman, sport*). Games have been resorted to in all ages and among all nations for the purposes of mental or physical exercise or amusement. The games of the ancient Greeks were religious solemnities, which brought the citizens of all the independent states of Greece in contact; and these festal communions (*πανηγύρεις*) served as the most popular bonds of social union among all who bore the Hellenic name. The four principal games were the OLYMPIAN, PYTHIAN, NEMEAN, and ISTHMIAN. (Wachsmuth's *Historical Antiquities of the Greeks*, ch. i. part ii. s. 22; Grote's *History of Greece*, part ii. ch. ii. See also the treatise of Barbeyrac on the *Morality of Games*.)

Gaming. In Law, all common gaming-houses are nuisances in the consideration of English law. The first statute against public gaming is the 33 Hen. VIII. c. 9. By 9 Anne c. 14 securities given for the repayment of money lent for purposes of gaming were declared to be void; and any person losing and

GAMMARINES

paying 10*l.* at one sitting might, within three months, recover the same with costs; but the severity of this Act was qualified by a subsequent statute (5 & 6 Wm. IV. c. 41) in favour of innocent holders of such securities. More recently it has been enacted that all agreements by way of gaming or wagering shall be void, and that money, &c., alleged to be won upon any wager shall not be legally recoverable; but this enactment does not apply to any subscription for or towards any plate, prize, or sum of money to be awarded to the winner of a lawful game, pastime, &c. (8 & 9 Vict. c. 109). But gaming as a public offence had never been satisfactorily dealt with until the last-mentioned Act (1846), which gave the power of summary conviction against persons engaged in keeping and managing public gaming-houses, and which was amended and rendered more stringent in 1854 by the stat. 17 & 18 Vict. c. 38. In France, where the privilege of keeping such houses had been farmed by a company for 6,000,000 francs annually, public gaming-houses were suppressed by the law of July 22, 1836, from January 1, 1838; and this example has been followed by most of the chief continental states, so that they now exist only in some small principalities, chiefly German, where the government has not yet been able to make up its mind to the loss of income which their abolition would occasion.

Gamma-function. The name sometimes given to the definite integral

$$\int_0^{\infty} e^{-x} x^{n-1} dx,$$

for which Legendre in his *Exercices du Calcul Intégral*, vol. ii., used the symbol $\Gamma(n)$, and proposed the name of *second Eulerian integral*, Euler having first examined its properties. These properties are very remarkable, and the more important since a great many definite integrals may be expressed by means of the gamma-function. For positive values of n it can easily be shown, by integrating by parts, that $\Gamma(n+1) = n\Gamma(n)$, and since, manifestly, $\Gamma(1) = 1$, it follows that for positive integral values of n ,

$$\Gamma(n+1) = 1 \cdot 2 \cdot 3 \dots n = n!$$

When n is a proper fraction, the following relation exists:

$$\Gamma(n) \cdot \Gamma(1-n) = \frac{\pi}{\sin \pi n},$$

and gives, for $n = \frac{1}{2}$, the value $\Gamma(\frac{1}{2}) = \sqrt{\pi}$. It may further be remarked that when $n = 1.4616321451\dots$, $\Gamma(n)$ has the minimum value 0.8856031944. Legendre, in his *Exercices*, gives a table of the values of $\log \Gamma\left(\frac{n}{1000}\right)$ for all integral values of n

between 1,000 and 2,000. Gauss, Lagrange, Jacobi, Dirichlet, and several other modern writers have contributed papers on the properties of this important transcendental function.

Gammarines. *Gammarina* (Gr. *γαμματος, a lobster*). The name of a family of

Amphipodous Crustaceans, having the genus *Gammarus*, or the sand-hopper, as the type.

Gammoning. The rope by which the bowsprit is bound firmly down to the cutwater. The object of the gammoning is to exercise a pressure opposite to the upward pressure of the forestays and jibs. The ropes of the gammoning are *frapped* to render them as taut as possible.

Gamomorphism (Gr. γαμέω, to marry, and μορφή, shape). That stage of development of organised beings in which the spermatic and germinal elements are formed, matured, and renovated, in preparation for another act of fecundation, as the commencement of a new genetic cycle. [ΠΡΟΤΟΜΟΡΦΙΚΗ and ΟΛΤΙΟΜΟΡΦΙΚΗ.]

Gamut or Gamma Ut. In Music, a scale whereon the musical notes are disposed in their several orders. Its invention is attributed to Guido Aricino, a monk of Tuscany; it is also called the *harmonical hand*, Guido having made use of the figure of the hand to demonstrate the progression of his sounds.

Gandharva. [CENTAURS.]

Ganglion (Gr. γάγγλιον, a knot). An enlargement in the course of a nerve. A tumour in the sheath of a tendon.

Ganglioneura (Gr. γάγγλιον, and νῆυρον, a nerve). A name applied by Rudolphi to the Molluscous and Articulate divisions of the animal kingdom, which are characterised by a ganglionic type of the nervous system. In the articulated gangliated animals the ganglia are always disposed symmetrically along the middle line of the body, and brought into communication by a double chord: these have therefore been termed *Homogangliata*. In the Mollusca, on the contrary, the ganglions are dispersed, and placed at a distance from each other and from the mesial plane, and are frequently unsymmetrical in their arrangement: these have therefore been termed *Heterogangliata*.

Ganglionic Structure (Gr. γάγγλιον). In Anatomy, ganglions are enlargements in the course of nerves resembling knots. Physiologically, the name is applied to collections of vesicular matter which are centres of nervous power to the fibres connected with them. The ganglionic system consists of: 1st, the ganglionic portion of the spinal nerves; 2nd, the internal ganglionic or sympathetic nerves, with their intravertebral connections, or the nerves regulating both the motions of the internal muscular organs, as the heart, stomach, intestines, &c., and the secretions, nutrition, absorption, &c. The ganglionic structure in the brain is frequently termed *grey matter*, as opposed to the *white matter*, or nerve fibres.

Gangrene (Gr. γάγγραινα, from γρᾶω, γρᾶνω, to feed upon, from its eating away the tissues). This term is used to denote a condition of the soft parts of the body closely approaching to death; the term *sphacellus* (Gr. σφάκελος) being more properly applied to absolute death or mortification.

Gangrene may be moist or dry. The former

is characterised by the escape of serum into the part, and by extravasation of blood, which coagulates and blackens. Gases are given out, and vesicles containing these gaseous results of decomposition appear on the skin, raising the cuticle; these are called *phlyctæna*. [PHLYCTÆNA.] Dry gangrene may be regarded as the result of arterial disease. It is generally observed in advanced age, though exceptional cases have been recorded in earlier life. It is best exemplified when gradual ossification of the small arterial trunks occurs; pain, heat, and redness being the first symptoms, after which the parts become gradually black and dry. The hands, forearms, and the feet are chiefly affected. It is this dry form of gangrene which is produced by the ingestion of ergot of rye. [ERGOTISM.]

Gangue. The mineral substances which accompany metallic ores in the veins of rocks.

Gangway. The opening in a ship's bulwarks by which persons are intended to enter the vessel.

Gannet. [PELECANUS and SULA.]

Ganocephala (γάνος, lustre, and κεφαλή, head). An order of fossil Reptiles distinguished by the sculptured and external polished or *ganoid* bony plates with which the entire head was defended. These include the *post-orbital* and *supertemporal* plates, which roof over the temporal fossæ. There are no occipital condyles. The teeth have converging inflected folds of cement at their basal half. The notochord is persistent; the vertebral arches and peripheral elements are ossified; the pleurapophyses are short and straight. There are pectoral and pelvic limbs, which are natatory and very small; large median and lateral *throat plates*; scales small, narrow, subganoid; traces of branchial arches. The order is found throughout the series of carboniferous rocks; and, so far as present palæontological knowledge extends, the ganocephalous reptiles were amongst the first to appear on our planet. [ARCHÆOSAURUS.]

Ganymedes (Gr. Γανυμήδης). In the Homeric Mythology, a son of Tros and Callirhoë, and brother of Ilus. Being the most beautiful of all mortals, he was taken by Zeus to be his cupbearer and to live among the gods on Olympus. Later writers added that he was borne aloft to heaven on an eagle sent by Zeus.

Gaol (Fr. geole, Ital. gaiola—for gabbia—a cage, from Lat. cavea). A prison. The present law relating to the building, repairing, and maintaining of gaols and houses of correction is regulated by the statutes 4 Geo. IV. c. 64, 5 Geo. IV. c. 12 and c. 85, and 2 & 3 Vict. c. 56 (1839), with several other amending Acts. No gaol can be erected under any less authority than that of an Act of Parliament. There must now be at least one common gaol and one house of correction in every county. Gaolers are appointed by the high sheriff; by 4 Geo. IV. they are forbidden to exercise any other trade or office, and must reside within the prison. As to the discipline and management of gaols, see PRISON. The *commission of gaol delivery*

GAPE

is one of those held by the judges of the superior courts to enable them to try and discharge prisoners in the gaols of counties which they visit at the Assizes [which see].

GAPE. In Ornithology, the opening between the mandibles of birds.

GARANCEINE. One of the colouring matters derived from madder.

GARCINIA (after Dr. Garcia, an Oriental traveller). This genus of *Clusiaceae* yields the Mangosteen and Gamboge. The plant which produces the Mangosteen is called *G. Mangostana*; and the fruit itself, about the size of an orange, has a thick rind enclosing a juicy pulp having, writes Dr. Abel, 'the whiteness and solubility of snow, and a refreshing delicate delicious flavour' compared to that of a compound of pineapple and peach. Gamboge is the yellow gum resin of *G. Cambogia* and *G. pictoria*, and of a pedicellate-flowered variety of *G. Morella*. It is chiefly imported from Siam by way of Singapore. [GAMBUGE.]

GARDANT or GUARDANT (Fr.). In Heraldry, a term applied to a beast when represented full-faced, as looking at the spectator. *Re-guardant*, when looking backwards.

GARDEN (Fr. *jardin*, Goth. *gards*, Lat. *hortus*, Gr. *χῆρος*). A piece of ground, attached to a house, and enclosed, in which are cultivated various vegetables, fruits, and flowers. In the infancy of civilised society, all these were cultivated in one enclosure; but as mankind advanced in civilisation and refinement, and the number of plants to be cultivated increased, it became necessary to adopt separate departments; and culinary vegetables came to be cultivated in the Kitchen garden, fruits in the Orchard, flowers in the Flower garden, ornamental trees and shrubs in the Shrubbery or Pleasure grounds, and timber trees in Plantations, Woods, and Forests. [GARDENING.]

GARDENIA (after Dr. Garden of Charleston). This genus of *Cinchonaceae* will be most familiar to ordinary readers through the Cape Jasmine, as it is called, *G. florida* and *G. radicans*, both beautiful evergreen stove-shrubs with jasmine-scented flowers, of which the double form is that most commonly seen. There are many species known, very varied in character. *G. gummifera* and *G. lucida* of India yield a fragrant resin like Elemi.

GARDENING. The art of cultivating a garden comprehends a great variety of objects. [GARDEN.] All these are generally included under the following heads: Horticulture, or the culture of culinary vegetables and fruits; Floriculture, which includes the culture of ornamental and curious flowers, shrubs, and trees; Arboriculture, which implies the culture of trees or shrubs used for various purposes in the arts and in general economy; and Landscape Gardening, or the general disposition of the scenery or landscape about a country residence. [HORTICULTURE; BOTANIC GARDEN; ARBORICULTURE; and LANDSCAPE GARDENING.]

GARGOYLE. [GURGOYLE.]

Garlic (A.-Sax. *garleac*). The bulb of

GARTER, ORDER OF THE

Allium sativum, used in cookery, and having what is called the *alliacous* odour and flavour very strongly developed.

Garlic, Oil of. This oil is obtained on distilling garlic with water. It has a yellow colour and an acrid disagreeable smell and taste. It is the sulphide of the radical *allyl*.

GARNET (Ital. *granata*, from the resemblance of its red colour to that of pomegranate seeds). A mineral of which there are several varieties. They are all silicates of different bases, which have been divided into the following six sub-species: 1. *Alumina-lime Garnet*, consisting of silicates of alumina and lime, and comprising Cinnamon-stone or Essonite, Grossular or Wiluite, Romanzovite, Topazolite, and Succinite; 2. *Alumina-magnesia Garnet*, composed of silicates of alumina and magnesia; Black Garnet from Arendal; 3. *Alumina-iron Garnet* consisting of silicates of alumina and iron, and comprising Allochroite, Almandine or Precious Garnet, and common Garnet; 4. *Alumina-manganese Garnet*, consisting of silicates of alumina and manganese [SPASSARTINE]; 5. *Iron-lime Garnet*, composed of silicates of iron and lime, and including Aplome, Colophonite, Melanite, and Pyreneite; 6. *Lime and Limestone Garnet* or *Ouvarovite*, composed of silicates of lime and oxide of chrome.

The Precious Garnet is employed in jewellery, while coarse Garnets are used instead of Emery for cutting gems and polishing metal and stone. [PRAOPE.]

GARNISHMENT. In Law, a warning or notice given to a party to appear in court give information. This technical term is used only in one or two instances. Thus *garnishment* or warning is given to a third person, in whose hands money is attached within the liberties of the city of London by process out of the Sheriffs' Court, who is termed a *garnishee*.

Garrote. [GARROTE.]

GARRISON (Mod. Lat. *garnitio*, *military stores*, &c.; Fr. *garnison*). A body of forces disposed in a fortress to defend it against the enemy, or to keep in subjection the inhabitants of the town where it is situated. A place where troops are quartered in barracks is called a *garrison*, to distinguish it from a *camp* or *cantonment*.

Garrote or Garotte. A mode of capital punishment employed in Spain. The criminal is seated on a stool with his back to a stake. A tight collar is passed round his throat, of which the ends nearly meet; the executioner, standing behind him, twists them closer by means of a screw: the death is instantaneous.

GARRYACEAE (Garrya, one of the genera). A small order of diclinous Exogens, typical of the Garryall alliance, and distinguished from *Helwingiaceae* by the amentaceous flowers and opposite exstipulate leaves. *Garrya elliptica* is an ornamental evergreen shrub.

GARTER. In Heraldry, the moiety or half of a bend.

Garter, Order of the. The commonly received story, which attributes the origin of

GAS

this illustrious order to the dropping of the countess of Salisbury's garter, is contradicted by many recent writers, who attribute its institution to Richard I., who tied thongs of leather as marks of distinction round the legs of several of his officers at the siege of Acre. In the opinion of Dr. Meyrick (*On Armour*, vol. ii. p. 54), the garter is nothing more than a symbol of unity. The order was, however, either founded or restored by Edward III., and, according to general opinion, either in the year 1344 or 1350. The first of these dates was that of a festival in which the king formed himself and his associates into a company, under the patronage of St. George: but nothing is said respecting the garter until the latter year. The statutes of the Garter have been revived and augmented by Henry V., Henry VIII., and George III. in 1805. It was generally called the Order of St. George until the reign of Edward VI.; St. George of Cappadocia, the tutelary saint of England, being likewise patron of this order. It originally consisted of twenty-six knights, the king being the chief; and the same number is still retained, with the addition of princes of the blood-royal as supernumeraries. In the beginning of the present century, it was estimated that eight emperors and twenty-eight foreign kings had been members of it. The number has since been much augmented. It is the most ancient of all the lay orders of chivalry, and may rightly be accounted the noblest in the world. The college of the order is held at the chapel of St. George, in the castle of Windsor. The vestments and ensigns of the order are, the mantle of blue velvet, changed to purple by Queen Elizabeth, but restored to the original colour by Charles I.; the surcoat of crimson velvet; the hood, which is now fixed to the mantle, a cap of black velvet with an *sigrette* of heron's feathers being worn on the head instead of it; the collar of gold, composed of twenty-six pieces made to resemble garters, with the badge of the order (the figure of St. George and the Dragon) pendent from it; and the garter of blue velvet. The lesser George, as it is called, is attached to a blue ribbon, passing from the left shoulder to the right hip. The officers of the order are: the prelate (the bishop of Winchester for the time being); the chancellor (the bishop of Oxford); the register (the dean of Windsor); garter king-at-arms (this officer combines two functions, being herald to the Order of the Garter, and also principal king-at-arms, the highest officer of the Herald's College under the earl marshal); and the usher or black rod. It has also a dean and twelve canons, &c., with twenty-six pensioners, or poor knights. The most authentic work on the Order of the Garter is that of the learned antiquary Elias Ashmole.

Gas (probably from the German *geist*, or *spirit*). This term is applied to all permanently elastic fluids, or airs differing from atmospheric air.

Gas Fittings. The different contrivances for the application of gas lighting, consisting of

GAS ILLUMINATION

the pipes and services, the meter, the various burners, such as the batwing, fishtail, cockspur, argand, sun burners, &c. The pipes are either of cast iron, when their dimensions exceed three inches in diameter, or they may be either cast or wrought iron of two inches in diameter: they are made of wrought iron when they are from two inches to half an inch diameter; and of pewter or of tin, when smaller than half an inch, or when let into plastering. In Paris, the service pipes are made almost entirely of lead. Copper pipes must be carefully avoided, as the gas not only corrodes them, but also forms an explosive compound with the copper. The meters may be either the wet or dry gas-meter. Of these, the former are more likely, at first, to mark against the company, and the latter to do so in the course of time. The burners are usually made *batwing* when they have to be exposed to the effects of sudden gusts of wind (as in street lamps, open lights, &c.); the batwing is composed of a nipple, across which a narrow slit is formed, through which the gas escapes in a thin flame; they are made *fishtail* when common gas is burnt without much care, and consist of the nipple pierced with two openings placed so that the jets cross one another; or they are made *cockspur*, which is a simple jet proceeding from the extremity of the nipple. The *argand burner*, of which *Leslie's burner* is an ingenious modification, is a ring pierced with holes, and surrounded with a glass shade, so that the supply of air may be regulated, and the light steadied; the *sun burner* is composed of fishtails, surrounded with a double cone, so contrived that the passage of air shall be uninterrupted round the flame, and a free egress offered to the ventilation. The skill of the gas-fitter must be shown in the adaptation of these various burners to the positions where they may be required; it being observed that they are all adapted to produce their best results when the pressure of the gas is equal to that of a column of water of one inch in height.

Gas Illumination. Under the head of CARBURETTED HYDROGEN we have adverted to two gaseous compounds of hydrogen and carbon which perform an important part in the economy of gas illumination. There are several other analogous compounds, which are produced in various relative proportions during the destructive distillation of pit coal, and which, therefore, are more or less concerned in the history of coal gas, which, as far as gas illumination is in question, may be defined as a mixture of many hydro-carburetted gases and vapours with a considerable volume of other gaseous bodies, among which free hydrogen and carbonic oxide are the most important.

The application of the gases produced from the destructive distillation of pit coal to the purposes of illumination is of modern invention; but the germ of it may be traced back for more than a century. The first authentic record of a permanent elastic and inflammable gas from coal occurs in the

GAS ILLUMINATION

Philosophical Transactions for 1739, in which there is a paper by the Rev. Dr. Clayton, describing the method of filling bladders with what he calls the *spirit of coal*, obtained by distilling coal in a retort upon an open fire. He says: 'I filled a good many bladders therewith, and might have filled an inconceivable number more, for the spirit continued to rise for several hours, and filled the bladders almost as fast as a man could have blown them, with his mouth, and yet the quantity of coals distilled was inconsiderable. I kept this spirit in the bladders a considerable time, and endeavoured in several ways to condense it, but in vain; and when I had a mind to divert strangers or friends, I have frequently taken one of these bladders, and pricked a hole therein with a pin, and compressing gently the bladder near the flame of a candle, till it once took fire, it would then continue flaming till all the spirit was compressed out of the bladder; which was the more surprising, because no one could discern any difference in the appearance between these bladders and those that were filled with common air.' Dr. Clayton seems also to have observed those curious phenomena which have since excited so much attention under the terms *exosmose* and *endosmose*; for he goes on to say that he found 'that this spirit must be kept in thick bladders, as in those of an ox or the like; for if I filled calves' bladders therewith, it would lose its inflammability in twenty-four hours, though the bladders became not relaxed at all.'

Dr. Hales (in his *Vegetable Statics*) and Dr. Watson (in his *Chemical Essays*) have each noticed the properties of the gas from coal; but it was not until the end of the last century that the practicability of substituting coal gas in place of other inflammables, for the lighting of streets and buildings, became an object of attention.

The idea of applying coal gas to economical purposes seems first to have occurred to Mr. William Murdoch, of Redruth, in Cornwall, in 1792. His apparatus consisted of an iron retort, and iron and copper tubes, through which the gas was conducted to a considerable distance, and was there, as well as at intermediate points, burnt through apertures of various forms and dimensions; he also washed the gas with water, and used other means for its purification. In 1798 Mr. Murdoch constructed a large and improved apparatus for the purpose of lighting Boulton and Watt's celebrated factory at Soho, near Birmingham, which, on the occasion of the peace in 1802, was publicly illuminated by the same means. ('An Account of the Application of Gas from Coal to Economical Purposes,' by Mr. W. Murdoch, *Phil. Trans.* 1808, p. 214.)

But the attention of the public in London was first called to this important subject by the experiments of Mr. Winsor, who in 1803 and 1804 lighted the Lyceum Theatre, and shortly afterwards one side of Pall Mall, with gas from coal. From that period the manufacture of gas suggested itself as a lucrative speculation. Seve-

ral private gas works were erected, and companies were formed for the purpose of carrying on the manufacture on an extended scale. Oil lamps were soon after banished from all the great thoroughfares of the metropolis; and in the course of from ten to fifteen years not only was every street and alley illuminated from the same source, but it was generally adopted in the theatres and other public buildings; was carried into the suburbs; and has now become general in every town and city of the empire and of the civilised world.

When coal is subjected to destructive distillation, i.e. when it is heated in close vessels, it yields a number of complicated products, which, so far as our present object is concerned, may be classed under three heads, namely: first, permanent gases; secondly, vapours which may be condensed into the liquid or solid state by cooling; thirdly, the fixed or residuary matter, which remains in the retort. The object of gas manufacture is to separate these from each other, and so to purify the gaseous products as to render them fit for combustion.

The apparatus employed for this purpose consists of: first, the *retorts*, as they are called, or cast-iron or fire-clay cylinders, in which the coal is subjected to heat; secondly, the contrivance for condensing the solid and liquid matters; thirdly, the purifiers, by which the gas is cleansed from the various matters which would be prejudicial if retained in it; and fourthly, the gasholders, in which the purified gas is ultimately received, and which are connected with the service pipes for its distribution. The following is a brief description of these several parts; but it is to be observed that gas-making is conducted upon rather different principles in such large towns as London, Paris, &c. from those which prevail in smaller works.

The retorts are of various forms and sizes, but always longer than wide or deep; they differ from about 7 ft. 6 in. long by 20 in. wide and 1 foot deep, to 20 ft. long by 20 in. wide and 13 in. deep, and in some cases they are made of still larger dimensions. They are usually of an arched shape, though sometimes they are perfectly cylindrical; they are of cast iron when in one piece, but when the manufacture is upon a sufficiently large scale to require their being built up of several parts, they are made of fire-clay. Upon the exposed end of the retorts there is placed the mouthpiece, which is of cast iron, and carries the door and ascending pipes, which communicate with the hydraulic main. This is a pipe, usually of cast iron, running along the front of the retort stack, half filled with water, destined to receive a portion of the tar and water passing over with the gas. Thence the gas passes to the condenser, where the tar and remainder of the tar water are deposited. It is to be observed that the quantity of tar will depend much on the temperature at which the distillation has been effected, and great attention is required for this purpose; if it be too high,

the retorts will be burnt out rapidly, and although the quantity of gas will be increased, its quality will be greatly deteriorated; if too low, the quantity of tar will be augmented, and the amount of the gas for illuminating purposes proportionally diminished. From the condensers, the gas passes into the *scrubbers*, where it is exposed to the purifying action of a stream of water passing over layers of coke, and thus deprived of ammonia. It is then conducted to the *purifiers*, where it passes through sieves (charged with hydrate of lime, or with hydrated oxide of iron), which remove sulphuretted hydrogen, and complete the process of purification; the gas is thence conducted through the station meter to the gasholder preparatory to distribution.

In practice, it is found that one ton of coal will yield from 8,000 to 10,000 cubic feet of purified gas, of average illuminating power, leaving a residue of about 15 bushels of coke, and producing about 9 gallons of tar. In London the retorts are charged constantly, so that they work day and night; and some idea of the magnitude of those establishments may be formed when it is stated that in the works of the Imperial Gas Company as much as 250 tons of coal are daily carbonised, and that they have one gasholder capable of containing $1\frac{1}{2}$ million cubic feet. There are thirteen gas companies in London, which consume about 1,500,000 tons of coal annually. It is calculated that the average consumption of gas by the bating burners in the street lamps is about five or six feet per hour, and the distance apart of those lamps is about 90 ft. on the same line of footpath; the rate of consumption in private lights, of course, varies very considerably, and no general rule can be laid down respecting it. The law that a light diminishes in intensity as the square of the distance increases, prevails in this case; but in spite of the great waste of gas that it entails, the sun lighting (as the system of concentrating the gas in one centre is called) appears to present such advantages that it is generally adopted in places of public resort.

Gas-meter. Any apparatus used for measuring the volume of gas. The term is, however, usually restricted to an instrument employed in measuring the amount of illuminating gas supplied to consumers. The wet meter was originally invented by the late Mr. Clegg, engineer to the Chartered Gas Works, and has been considerably improved by Mr. Crossley; the dry meter was invented by Mr. John Malam, and has been improved by Mr. Defries. The wet meter consists of a drum, which is made to revolve upon its axis by the ingress and the egress of the gas; this drum works in water, which is regulated so that when the level of it exceeds a certain line, the passage of the gas is intercepted, and when it falls below another line a valve is disengaged that shuts off the entrance of the gas. All that is necessary under these circumstances is to preserve accurately the water-level; and

many inventions have been proposed for this purpose, of which Crossley and Goldsmith's patent appears to be the most successful. There is a set of multiplying wheels upon the face, to which the motion of the drum is communicated, and by which the rate of consumption is regulated. The dry gas-meter consists of a vessel in which the gas is introduced into the sides of an apparatus which has a number of diaphragms fixed on the centre or upright division, the other end being loose, so as to be able to expand or contract as the gas fills it; the multiplying wheels are placed in connection with the diaphragms, which work upon the train of wheels by their alternate motion. The great difficulty about these dry gas-meters is to secure the regular passage of the gas through the respective openings, in consequence of the defects in the quality of the leather; if this be effected carefully, and in a lasting manner, there can be no doubt but that the dry gas-meter is superior to the wet one, especially for private consumption, where it is not always possible to secure the care and attention required for the regularity of the water-line. For the purposes of the *station meter*, or that which is used for measuring the quantity of gas made in the factory before it proceeds to the holder, and thence to distribution, there can be no hesitation as to the preference to be accorded to the wet meter. [PHOTOMETRY; RESIDUAL PRODUCTS OF GAS MANUFACTURE.]

Gascolgne's Powder. A compound of absorbent powders with *bezoar*: it was formerly held in great repute as an antidote to poison.

Gases, Diffusion of. If two gases be brought into communication with each other, they will gradually mix or diffuse through each other, although their mingling may have to take place in opposition to gravity. Thus, if a bottle of carbonic acid be connected, even by a narrow tube, with a bottle of hydrogen placed vertically above it, some of the heavy carbonic acid will gradually make its way into the upper bottle, whilst a corresponding volume of the light hydrogen will descend into the lower one. In a few days the two gases will be found completely mixed. The same effect takes place if the gases be divided by a porous diaphragm, such as a plate of gypsum or artificial graphite. It is this property of diffusion which preserves a nearly constant composition in our atmosphere at all accessible heights and over the whole surface of the globe. The chief constituents of the air, differing as they do in specific gravity, could not maintain this constant mixture without diffusion, but would form separate layers floating one above the other. Graham has investigated this phenomenon; and has established the law, that the relative diffusibilities of different gases are inversely as the square roots of their specific gravities.

The following table exhibits, in a condensed form, the results of Mr. Graham's experiments, which are given in the last column, compared with the numbers calculated from $\frac{1}{\sqrt{\text{sp. gr.}}}$:-

GASES, EFFUSION OF

Name of Gas	Sp. gr.	Sq. root of sp. gr.	$\frac{1}{\sqrt{\text{sp. gr.}}}$	Velocity of Diffusion Air = 1
Hydrogen . . .	00928	2632	3.7794	3.83
Marsh Gas . . .	559	7478	1.3375	1.844
Steam . . .	6235	7896	1.2664	
Carbonic Oxide . .	9678	9837	1.0165	1.0149
Nitrogen . . .	9713	9856	1.0147	1.0143
Oleasant Gas . . .	978	9889	1.0112	1.0191
Nitric Oxide . . .	1.039	1.0196	.9808	
Oxygen . . .	1.1056	1.0515	.9610	.9487
Sulphuretted Hydrogen . . .	1.1912	1.0914	.9162	.95
Nitrous Oxide . .	1.527	1.2357	.8092	.82
Carbonic Acid . .	1.529	1.2365	.8087	.812
Sulphurous Acid .	2.247	1.4991	.6671	.68

Gases, Effusion of. A term used to signify the passage of a gas into a vacuum, through a fine and infinitely short tube; for instance, through a minute aperture in a thin plate of metal. Graham has proved that the velocity of effusion is the same as that of diffusion; or, in other words, gases flow into a vacuum at rates inversely proportional to the square roots of their specific gravities.

Gases, Liquefaction of. The solid, liquid, and gaseous conditions of a body obviously depend upon temperature and pressure. At the ordinary atmospheric pressure, water, for instance, is a solid at temperatures below 32°; a liquid at temperatures between 32° and 212°; and a gas at all higher temperatures. If this gas be cooled, it first liquefies and then solidifies. All gases if sufficiently cooled and pressed would probably become liquids and solids. Many of the gases which are permanent at ordinary atmospheric pressure and temperature, become liquids on increasing the pressure and diminishing the temperature, and some even solidify when cooled sufficiently. Thus sulphurous acid gas liquefies even at 32° if the pressure be increased by half an atmosphere; at -105° it is solid. Carbonic acid liquefies at a pressure of thirty-eight atmospheres, and at -70° is a solid. So cyanogen, hydric acid, ammonia, sulphuretted hydrogen, nitrous oxide, euchlorine, hydrobromic acid, fluoride of silicon, chlorine, arseniuretted hydrogen, olefant gas, ethyl, fluoride of boron, and hydrochloric acid gases can be liquefied. But hydrogen, nitrogen, carbonic oxide and nitric oxide resist liquefaction at the enormous pressure of 800, and the first two even at 1,500, atmospheres, the temperature being low at the same time.

Gases, Transpiration of. The passage of gases through capillary tubes is denoted by this term. The rates at which various gases flow through such tubes has been investigated by Graham, who arrived at the following results:—

1. The velocity of transpiration of any gas increases, *ceteris paribus*, directly as the pressure.
2. The diameter of the tube remaining constant, the volume of gas transpired in equal times is inversely as the length of the tube.
3. Any rise of temperature renders the rate of transpiration slower.

GASTEROPODS

4. The rate of transpiration is independent of the nature of the material composing the tube.

5. Equal weights of oxygen, nitrogen, air, and carbonic oxide are transpired in equal times.

6. The velocities of transpiration of nitrogen, nitric oxide, and carbonic oxide are equal.

7. The transpiration velocities of hydrochloric acid, carbonic acid and nitrous oxide are equal; as are also those of hydrogen and vapour of ether.

Gas-holder. A hollow cylindrical vessel open at bottom and closed at top, suspended by counterpoises in a tank of water, so that it may be filled with gas introduced by a central pipe, and the gas afterwards distributed by proper pressure through the mains which convey it for service. Some of these magazines of coal-gas are of an enormous size, holding a million cubic feet and upwards.

Gasket. A plaited cord, by which the sails when furled are kept bound up close to the yards or gaffs. The same term is applied to the plaited hemp used for packing the piston of the steam engine and its pumps.

Gasometer. This term is often applied to the gas-holders of coal-gas works; but it is more properly limited to a smaller instrument, constructed upon more delicate principles, and capable of accurately measuring the quantity of gas of any kind which passes into and out of it. These instruments are sometimes constructed of glass and iron, for the purpose of containing mercury, so as to be used for gases which are absorbable by water.

Gasometric Analysis. *Eudiometry*, or the process of separating and estimating the individual constituents of a gaseous mixture. Such an estimation is effected either by the action of absorbents on small volumes of the gas contained in graduated tubes called *eudiometers*; or by exploding the gas with oxygen, and noticing the volumes before and after explosion.

The explosion of combustible gases mixed with oxygen is effected by an electric spark caused to pass through them between the ends of two platinum wires fused into the sides of the eudiometer. The actual operations of transferring, mixing, measuring, exploding and absorbing gases have been greatly facilitated of late years by the labours of Bunsen, Regnault and others. (See article 'Analysis Volumetric of Gases,' in *Watt's Dictionary of Chemistry*.) Much inconvenience and labour of calculation are also now avoided, and greater rapidity of manipulation and accuracy of result obtained, by performing the analysis at one constant temperature.

Gasteropods, Gasteropoda (Gr. *γαστήρ*, the belly, and *πούς*, foot). The name of a class of Molluscous animals, comprehending those which have a ventral muscular disc of greater or less extent, adapted for creeping. The class is divided, according to the modifications of the breathing organs, into the orders *Pulmonata*, *Nudibranchiata*, *Infusibranchiata*, *Tectibranchiata*, *Pectinibranchiata*, *Tubulibranchiata*,

Scutibranchiata, and *Cyclobranchiata*. The *Carinaria*, in which the ventral foot is reduced to a rudimental compressed plate, forms the type of an aberrant group or order, called *Heteropoda*. The pulmonated snail or slug may be regarded as types of the Gasteropodous Molluscs.

Gastornis (from Gaston Plante, the discoverer, and *ὄρνις*, bird). A genus of fossil birds which has been found in the conglomerate and plastic clay at the base of the Eocene Tertiaries, at Meudon, near Paris. The leg and thigh bones, which alone are known, indicate a species as large as an ostrich, but more robust, and with affinities to wading and aquatic birds.

Gastræum (Gr. *γαστήρ*). A term in Zoology, applied to the whole of the prone or under surface of an animal's body.

Gastric Juice. The peculiar fluid secreted by the stomach, and essential to the process of digestion. When collected from the stomach of an animal killed while fasting, it is transparent and saline, but during digestion it is distinctly acid; and Dr. Prout found that the free acid which it contains is the hydrochloric. One of the most characteristic properties of the gastric juice is its solvent power over the varieties of animal fibre, or albumen, and the facility with which it coagulates milk, and then dissolves the coagulum. [DIGESTION; Pepsine.]

Gastriloquus. [VENTRILLOQUIST.]

Gastritis. Inflammation of the stomach. It is attended by great irritability of the stomach, indicated by hiccup, vomiting, and much pain and general uneasiness; the pulse is small and hard, and there is fever, attended by prostration of strength. It is a very dangerous disease, and requires prompt treatment; especially bleeding, general and local; blisters; hot bath, or fomentation. The constant sickness generally prevents the exhibition of any of the ordinary remedies. When it arises from poison, the stomach-pump and other distinct treatment is often requisite. Idiopathic gastritis is scarcely recognised by the medical profession; the inflammation observed being always traceable to gout, or to the ingestion of irritating liquids or substances.

Gastrochæna (Gr. *γαστήρ*, and *χαίρω*, *I gape*). A genus of Bivalve Molluscs, in which a large hiatus or gape intervenes between the closed valves on the ventral aspect of the animal. The mantle is perforated, opposite to this gape, by a small aperture for the passage of the foot; and is prolonged posteriorly into two muscular tubes or siphons. The *Gastrochænes* inhabit burrows, which they make in the substance of madrepores or calcareous rocks, lining their perforations with a calcareous tube.

Gastrocnemius (Gr. *γαστροκνήμην*, *the calf of the leg*). The muscle which principally forms the calf of the leg.

Gastrodynia (Gr. *γαστήρ*, and *δύσση*, *pain*). A painful affection of the stomach, often attendant upon dyspepsia.

Gastrolobium (Gr. *γαστήρ*, *a belly*, and *λοβός*, *a pod*). Like the allied *Gompholobia*,

this beautiful genus of Leguminous Australian bushes is most destructive to sheep and cattle. In the western settlements, along with their near allies just mentioned, the species are known as Poison-plants. *G. bilobum*, *grandiflorum*, and *spinosum* appear to be amongst the most virulent of the species. Death is speedy and certain after browsing on the foliage, and large numbers of animals are annually lost in this way.

Gastromancy (Gr. *γαστήρ*, and *μαντεία*, *prophesy*). A kind of divination practised among the ancients by means of words supposed to issue from the belly.

Gastronomy (Gr. *γαστρονομία*). The so-called science of eating and drinking. [FOOD.]

Gastrography (Gr. *γαστήρ*, and *γράφω*, *I scrib*). In Surgery, the operation of sewing up wounds of the abdomen.

Gastrotomy (Gr. *γαστήρ*, and *τέμνω*, *I cut*). The operation of cutting into the abdomen.

Gathering. In Printing, making up the sheets, after they are printed, into a complete set ready for the bookbinder.

Gauge Point. A term used in Gauging, to denote the diameter of a cylinder whose altitude is one inch, and its content equal to that of a unit of a given measure. For example, the old wine gallon contained 231 cubic inches. The diameter of a cylinder of the same capacity, and whose altitude is one inch, is 17·15 inches; which, therefore, is the gauge point for this measure.

Gauges, Steam and Water (Fr. *jauge*). The apparatuses fixed to every well-built boiler for ascertaining the force of steam and the level of the water. The first consists of a siphon tube containing mercury in the case of low-pressure engines, and of a spiral spring attached to a wheel indicator in the case of high-pressure engines. The last consists of a vertical glass tube or flat case communicating, above and below, with the boiler. Gauge cocks are sometimes put instead of, or in addition to, the tubes for the purpose of enabling the engineer to verify the water-level.

Gauging. In Astronomy, a process devised by Sir W. Herschel for counting the stars. It consisted in numbering those of all magnitudes which occurred in single fields of view of 15 inches diameter, visible through his reflector of 18 inches aperture, and 20 feet focal length, with a magnifying power of 180.

Gauging. In Mensuration, the measuring of the capacities of vessels, chiefly casks, barrels, vats, &c. The principles of gauging are those which geometry furnishes for the measurement of solids in general. (Symon's *Practical Gauger*; Leadbetter's *Treatise on Gauging*; Hutton's *Mensuration*, &c.)

Gauging Rule. [SLIDING RULE.]

Gault. The name locally given to a division of the upper cretaceous rocks in England. It is a provincial term. The rocks so called are chiefly developed near Folkestone and in Cambridgeshire.

GAULTHERIA

Gault is understood to mean a peculiar brick clay of a blue colour, having occasional calcareous concretions, and certain characteristic fossils, among which are bones of a bird. Beds of the same age occur as compact sandstones in the Blackdown Hills, Devonshire, and are there worked for building purposes. These beds are also rich in fossils.

The gault lies between the lower and the upper greensand. It is represented in Germany by the *Lower Pläner* of the north of Germany, a rock often containing hippurites. [HIPPURITES.] A remarkable schistose bed in the canton of Glarus in Switzerland, celebrated for its fossil fishes, is of this period. In France there is a bed, argillaceous like the gault, cropping out below beds which represent the upper greensand, at Mons in the valley of the Loire.

Gaultheria (after Dr. Gauthier). Under the names Partridge-berry, Deer-berry, Teaberry, Box-berry, &c., are known the fruits of *G. procumbens*, which afford winter food for partridges, deer, and other wild animals. The plant is called Wintergreen in North America, and has a peculiar aromatic odour and flavour, due to the presence of a volatile oil, obtained by distillation, and known as Wintergreen oil. The plant is also called Mountain Tea, and its leaves are used as a substitute for genuine tea. *G. Shallon* produces dark purple berries, which form excellent tarts.

Gauntlet, Running the. A barbarous punishment formerly enforced in the navy, by which the criminal was obliged to pass between the seamen arranged in two rows, and provided with knotted cords, with which they flogged him.

Gauntlets (Fr. gantelet). Gloves of armour, originally formed of chain mail, later of plate, and articulated at the fingers. A gauntlet was thrown down to challenge an adversary, who, by taking it up, accepted the challenge. It was till recently the custom at the coronation of a sovereign in this country for the hereditary champion of England to throw down a gauntlet in Westminster Hall, and challenge all disputants of the crown. [CHAMPION.]

Gauze (Fr. gaze). A textile fabric generally made of silk, and said to have been invented in Gaza, a city of Palestine.

Gavelkind (A.-Sax.). An old English custom or tenure annexed to all lands in the county of Kent not especially exempted, by which the land of the father is equally divided at his death among all his sons, or the land of the brother among all his brethren if he have no issue of his own. Tenure in gavelkind is considered by Blackstone to have been in the nature of free socage. In most places the gavelkind tenant had the power of devising by will before the Statute of Wills. The same custom seems to have been prevalent in Wales, where all gavelkind lands were made descendible to the heir at common law by stat. 34 & 35 Hen. VIII. c. 36. In Kent the lands have been in particular cases disgavelled, or deprived of their customary descendible quality, by statute, but all land in Kent is *prima facie* gavelkind.

GEHENNA

Gavial. [CROCODILE.]

Gavot (Fr. gavotte). In Music, an air for a dance, which has two strains; the first having usually four or eight bars, and the second eight or twelve more, each of which are played twice over. It is of a brisk nature.

Gaylussite. A mineral named after Gay Lussac, found at Lagunilla, near Merida; it is composed of nearly equal weights of carbonate of soda, carbonate of lime, and water.

Gazelle (Fr. from the Arabic al-gazal). The name of a small, swift, and elegantly formed species of Antelope, the *Antelope dorcas* of Linnaeus; famed for the lustre and soft expression of its large dark eyes.

Gazette (Fr.; Ital. gazetta). A periodical paper, published at short intervals, containing articles of general intelligence. Both on the Continent and in England such sheets were generally termed *Mercuries* in the first times of their invention, and appeared only occasionally the earliest among ourselves are said to have been published during the general apprehension from the presence of the Spanish armada; but doubt has been thrown on the authenticity of the specimens preserved in the British Museum. The first gazette produced in France (under that title) was in 1631; the first in England in 1665, when the court resided at Oxford on account of the plague of London. From that period the *Gazette* has appeared regularly twice a week, containing such notifications as are either published by the court or the government, or such as are authoritatively required by law in private transactions. [NEWSPAPER.]

Gazetteer. This term denotes any work containing a brief account of all or any of the countries of the world, arranged in alphabetical order. To this class belong Brookes's *General Gazetteer*, and similar works.

Gasolites. [ÆEOLITES.]

Gear or Geer. In Mechanics, a term applied in mill-work to wheels, or wheels and pinions, acting into each other. *Spur gear* signifies wheels acting together in the same plane, with their axes parallel; for example, the wheel and trundle. *Bevel gear* is applied to wheels acting together whose axes are inclined to each other.

Geckotil. A family of lizards having for its type the genus *Gecko*; in which most of the species present a curious organisation of the foot, by which the sole is converted into a sucker, each toe being converted into a sucking disc, enabling the animal to creep up vertical walls and along ceilings against gravity, like the flies upon which they feed.

Gehenna. This word, meaning in Hebrew the valley of Hinnom, where the Jews burnt their sons and daughters in the fire to Moloch, is in the authorised version of the Scriptures translated by *hell*. By mediæval writers it was used not only in this sense, but generally in that of pain and suffering. Thus was produced the verb *gehenner*, to torture, which has passed into the modern French *gêner*, to annoy. (Max

Müller, *Lectures on Language*, 2nd series, p. 239.)

Gehlenite. A mineral in small grey or yellow crystals, found in the valley of Fassa in the Tyrol, named in honour of Gehlen the chemist. It is a basic silicate of alumina and lime with some iron and magnesia.

Gelée (Gr. *γῆλος*, of earth). The soluble brown matter which may be extracted from soils by the action of water. [HUMIC ACP.]

Gelalcean Era. The era of Yezdegird, so called from its reform by Gelal-Edin, sultan of Khorassan. [ERA.]

Gelatine (Lat. *gelu*, ice). An abundant proximate principle in animals. It is confined to the solid parts of the body, such as tendons, ligaments, cartilages, and bones, and exists nearly pure in the skin; but it is not contained in any healthy animal fluid. Its leading character is the formation of a tremulous jelly, when its solution in boiling water cools; it may be repeatedly liquefied, and again gelatinised, by the alternate application of heat and cold. Isinglass, glue, and size are various forms of gelatine, the first being this substance in a very pure state. Its most distinctive chemical character is the formation of a dense white precipitate when its solution in warm water is poured into an infusion of galls or other form of vegetable tannin. A solution of one part of gelatine in 5,000 of water is rendered slightly turbid by the addition of a strong tincture of galls. Gelatine is a nutritious article of food. The ultimate components of gelatine are 47·8 carbon, 7·9 hydrogen, 16·9 nitrogen, 27·4 oxygen.

Gelatines (Fr. *gelatine*). Mr. Kirby thus renders the term *Radiaria molasses* of Lamarck, by which are designated the radiated animals called *Aculephes* by Cuvier: the bodies of these Radiaria are generally of a gelatinous consistency.

Gem (Lat. *gemma*). In Sculpture, the practice of carving gems is of remote antiquity, though it is doubtful whether the ancients were able to cut the diamond or use the emerald and topaz for sculptural purposes. The stones usually selected are rock crystal of different colours, jasper, chalcedony, onyx, cornelian, and blood stone. Among the Greeks the art was carried to great perfection. Like the other arts, it fell into disuse; but since its revival in Italy in the fifteenth century, modern masters have more than rivalled some of the ancient productions.

Gems, Artificial. These are made of a transparent and dense glass, or *paste*, as it is called, containing a large proportion of oxide of lead, and generally some borax: the colours are given by metallic oxides. Much of their perfection depends upon the skill with which the exact tint of the real stone is imitated, and upon the care with which they are cut and polished. [GLASS.]

Gemara. [TALMUD.]

Gemini (Lat. *the twins*). The third sign of the zodiac, into which the sun enters about the

21st of May in each year. The constellation of the same name is easily distinguished by means of two conspicuous stars of the second magnitude near together; Castor being farthest to the west, and Pollux farthest to the east. Castor is one of the largest and finest double stars in the northern hemisphere. Its constituent stars form a binary system revolving in about 250 years.

Gemitrices (coined from Lat. *gemo*, to moan or coo). In Ornithology, an order of birds comprising the *Columbina* or pigeons.

Gemma (Lat.). In Botany, the name for a leaf-bud.

Gemmation (Lat. *gemma*). In Botany, the act of budding.

Gemmipara (Lat. *gemma*, a bud, and *pario*, I produce). The animals which propagate by buds, as the *hydra*, or fresh-water polype, &c.

Gemmule (Lat. *gemma*). In Botany, sometimes applied to the ovule or young seed, and sometimes to the plumule of the perfect seed.

Gena (Lat. *the cheek*). A term applied in Zoology to the region between the eye and the mouth, generally extended over the zygomatic arch.

Gendarmes or **Gens d'Armes** (Fr.). In the fourteenth and fifteenth centuries, the heavy French cavalry, which constituted the only national force, were termed *gens d'armes*, or *hommes d'armes*, men-at-arms. Each lancer had several followers on horseback, attached to him in various capacities; so that a *lance*, in the language of historians of that epoch, comprehends from three to ten men. In course of time the name of gendarmes ceased to be thus applied, and was given to the king's guards. It was afterwards transferred to a corps of police, and is now applied to the ordinary police force of the country, except in Paris, which is under special regulations. The French gendarmerie is composed of six legions, comprising about 15,800 men. (Bouillet, *Dictionnaire Universel*.) In all the German states, there is a body of mounted military police, with this appellation, of which the German equivalent is *Landdragoner*.

Gender (Lat. *genus*). In Grammar, the designation of sex by the form of a word.

Genealogy (Gr. *γενεαλογία*, from *γενεα*, family, and *λόγος*). The pedigree of a family. A series of several persons, descended from a common progenitor, is called a *line*. A direct line is either ascending (father, grandfather, &c.): in the civil law particular names were given to seven degrees in this line) or descending (son, grandson, &c.). The collateral lines comprehend the several lines which unite in a common progenitor; and are either equal or unequal, as the number of degrees in the lines is the same or different. The collateral relations on the father's side are termed in the civil law *cognati*, on the mother's *agnati*.

General. In the Army, this, next to that of field-marshal, is the highest military title adopted by the European states. The name designates

GENERAL ASSEMBLY

his command as having the *general* or highest orders to give in battle. There are a number of general officers in all European armies. In our service there are three ranks, the highest *general*, the second *lieutenant-general*, the junior rank *major-general*. The colonels of regiments are always general officers.

General Assembly of the Church of Scotland. [ASSEMBLY; PRESBYTERIANS.]

General, Brigadier. [BRIGADE.]

Generalisation. In Logic, has been defined as the act of comprehending under a common name several objects agreeing in some point which we abstract from each of them, and which that common term serves to indicate. (Whately's *Logic*, p. 388.)

Generalissimo. A title conferred, especially by the French, on the commander-in-chief of an army consisting of two or more grand divisions, each under the superintendence of a general. According to Balzac, this dignity was first assumed by Cardinal Richelieu on the occasion of his leading the French army into Italy; but the term does not appear to have found favour among the other European states.

Generality. A French territorial division under the government prior to the Revolution. The generalities amounted in all to thirty-four. This division was principally with reference to the collection of taxes.

Generating Function. A name given by Laplace in his *Théorie des Probabilités* to that function which, when developed in a series of powers of its independent variable, *generates* given expressions in the form of coefficients. Thus

the generating function of n is $\frac{x}{(1-x)^2}$ since

the coefficient of x^n in the expansion of this fraction is n . Generally, if $u_n x^n$ be the general term in the expansion of a function $\phi(x)$, then the latter is said to be the *generating function* of u_n , and the relation between $\phi(x)$ and u_n is expressed by the symbolical equation

$$\phi(x) = G(u_n).$$

Thus, in the above example,

$$\frac{x}{(1-x)^2} = G(n).$$

The theory of generating functions is of importance in the calculus of differences. (Sir J. Herschel's *Examples of the Calculus of Differences*, 1813; and Boole's *Treatise on the Calculus of Differences*, 1860.)

Generator (Lat.). In Geometry, denotes a point, line, or surface by whose motion another curve or surface is or may be conceived to be described or defined. The term is most frequently applied to the right lines on a ruled surface.

Genesis, Book of. [PENTATEUCH.]

Genethliac (Gr. γενεθλιακον, from γενεθλη, birth). An ode or other short poem composed in honour of the birth of an individual.

Genethliaci (Lat. from Gr. γενεθλη, birth).

A name given at Rome to those who professed to predict the future of a man by means of the stars which presided at his nativity. They were

GENIUS

also called *Mathematici*, from their use of diagrams like those employed by geometers.

Genette (Fr.). A small variety of horse. Also an animal of the civet kind (*Viverridæ*), having a musky odour.

Geneva. [GIN.]

Geniculate (Lat. geniculatus; from genu, the knee). In Botany, bending abruptly in an obtuse angle, like the knee when a little bent, as in the stems of some grasses.

Genii. Called by the Eastern nations Ginn or djinn, are a race of beings created from fire, endowed with a corporeal form, which they are capable of metamorphosing at pleasure. They are said to have inhabited this earth many ages before the creation of man, and to have been at last driven thence for rebellious conduct against Allah. Their present place of abode is *Ginnistan*, the Persian Elysium; but they are represented as still interesting themselves in the affairs of this earth. A more correct idea may be formed of their origin, characteristics, and history, from a perusal of the *Arabian Nights' Entertainments*, than can be conveyed by the most elaborate dissertation. For an account of the superstitions of the modern Arabs in regard to genii, see Lane's *Modern Egyptians*. [GENIUS.]

Genioglossi (Gr. γένειον, the chin, and γλῶσσα, the tongue). In Anatomy, a pair of muscles by which the tongue is protruded.

Genipa (genipapo, the Guiana name). The Genipap fruit of South America, as large as an orange and agreeably flavoured, is obtained from a plant of this Cinchonaceous genus called *G. americana*. In Surinam it is known by the name of Marmalade Box.

Genista (Lat. the broom plant). A genus of *Leguminosæ*, one of which is the *planta genista* or *plante genêt* of the French, from which the Plantagenets took their name. *G. tinctoria* was formerly of some importance as a dye plant, and was known by the name of Dyer's Greenweed, or Dyer's Broom, the green colour being obtained by dipping the yellowed articles obtained by its agency in a solution of wood. Kendal green was obtained by this process. The common Broom is now, however, generally referred to the genus *SAROTHAMNUS*.

Genitive Case (Lat. genitivus, generative). That inflection of the noun which denotes relation. With Aristotle it was the predicating case, which determined the class or genus to which a thing belonged. As such, it had no reference to origin or birth. The Greek genitive was formed by the same suffix which converted a noun substantive into an adjective. (Max Müller's *Lectures on Language*, first series, p. 104.) [GRAMMAR.]

Genius (Lat.). According to the belief of the old Italian races, especially the Etruscans, the genius was a spiritual agency of very indeterminate character, which seems to have been appropriated not only to every human family, but to every god, and even to places and things. The life of the genius ceased with that of the

GENNET, ORDER OF THE

person whom he guarded. (Sir G. C. Lewis, *Astronomy of the Ancients*, p. 313.) This conception was altogether foreign to Grecian mythology, although in later times it became mingled in that of Rome with the Grecian notions respecting demons. [Dæmon.] Censorinus (*De Die Natali*) says, 'The genius is that god under whose protection every mortal is born and lives.' Hence the worship of the genius was closely connected with all domestic ceremonies and feelings; the marriage bed was *lectus genialis*; the day of the genius, *genialis dies*, was sacred to mirth and relaxation; the genius accompanied human fortunes in their vicissitudes (*Vultu mutabilis, albus et ater—Hor.*); and death was typified by the figure of a genius with a lamp reversed. The genii of places were usually represented and worshipped under the figure of snakes. Whether there is any connection between the Italic genius and the djinn of Oriental nations [GENII] is a doubtful point.

Gennet, Order of the. The first order of chivalry known in France, founded by Charles Martel after his defeat of the Saracens at Tours in 726. It received its name from the gennet or wood-martin, to commemorate the aid supposed to be given by St. Martin of Tours towards defeating the enemy.

Genouillère (Fr.). In Fortification, the part of the interior slope of the parapet below the sill of an embrasure. It covers the lower part of the gun-carriage. In armour of the fourteenth century, the knee-piece or knee-boss.

Genre (Fr. du genre bas, of a low kind). In Painting, a term applied to express a class of pictures which belong to none of the higher or specific classes of art. It refers commonly, as the full French expression implies, to ordinary scenes of vulgar life. Yet a *peintre de genre* or *genre-painter* is not necessarily a painter of low subjects, nor need a *genre* picture be vulgar in the common acceptance of the word. The Dutch are the great *genre* painters; and the style was also known to the ancients. Pyreicus, a famous Greek painter of this class, was called *πυραγορυπιδος*, literally *dirt-painter*, or *πυρορυπιδος*, from *πυρος*, *common ware* or *trumpery*. He painted barbers' shops, cobblers' stalls, shell-fish, eatables of all sorts, and the like, and his pictures were highly valued. (Pliny xxxv. 37.)

Gens (Lat.). In ancient History, a clan or sect, forming a subdivision of the Roman people next in order to the curia or tribe. The members and houses (*familia*) composing one of these clans were not necessarily united by ties of blood, but were originally brought together by a political distribution of the citizens, and bound by religious rites, and a common name, derived generally from some eponymous hero. This common name, which distinguished the *gentiles* or members of the same clan, was the second of the three borne by a Roman citizen, and was specially termed the *nomen*. It is supposed that each of the *curies* originally contained ten *gentes*, and that each of these

GENTLEMAN

was represented in the senate by one of its members. (Vico, *Scienza Nuova*; Niebuhr's *History of Rome*; Mommsen's *History of Rome*.)

Gentian (said to be so named after Gentius, an Illyrian king). The Gentian root of the shops is the produce of plants of this genus, and principally of *G. lutea*, but those of *G. purpurea*, *annonica*, and *punctata* are similarly employed, and indeed all the species are pervaded by a pure bitter principle which renders them valuable as tonics. Some of the species are found on the European Alps near the snow-line, and their bold cerulean blossoms are greatly admired.

Gentianaceæ (Gentiana, one of the genera). A natural order of herbaceous Exogens of the Gentianial alliance inhabiting most parts of the world. They are very near to *Apocynaceæ*, from which they differ in their herbaceous habit, permanent corolla, want of milk, and in many other characters. From *Scrophulariaceæ* they are distinguished by their regular flowers, the stamens of which are equal in number to the lobes of the corolla. Their chief sensible property is an intense bitterness, which resides both in the stems and roots.

Gentianic Acid. *Gentianin*. A crystallisable body contained in Gentian root.

Gentile (Lat. gentilis, from gens, nation). The original meaning of the Latin word *gentilis* is, one of the same kith or nation with the speaker. The Jews designated all who did not profess their religion indiscriminately as the *nations*, *τὰ ἔθνη*; and hence the Greek word *ἔθνος* and the corresponding Latin word *gentile* became used to signify Pagans, in opposition to Christians and Jews. The word *gentilis* is used in this sense by St. Jerome, Prudentius, and Christian writers of that age in general. The jealousy with which the Jews regarded all foreign nations, and the obstinacy with which they clung to the notion of their own peculiar sanctity, are well known. The earlier half of the history of the Acts contains the account of the struggle which Christianity maintained against these prejudices before it finally subdued them. The observance of certain Jewish ceremonies continued, however, for a long time to be a stumbling block to the most devout and sincere Christians. Even in the post-apostolic age, the judaising party formed a distinct division of the Christian world, split itself into various sects, such as the Ebionites and Nicolaitans, and for a long time exercised considerable influence even within the pale of the church.

Gentleman (the English word *gentile* in its original sense signifies one belonging to a race or family; Lat. gens). In Heraldry, a rank expressed in Latin by the term *generosus*. All entitled to coat-armour are gentlemen; but the name is more commonly applied to the lowest rank of those who have no other distinguishing title. Gentlemen by blood were those who could show four generations of gentlemen, both in the paternal and maternal line. Those who could not prove this, but against whom the contrary was not known within memory of

GENTLEMAN USHER

man, were gentlemen by prescription. Gentlemen were also created by letters patent of the king. Officers (not menial) of the king's household, persons holding a royal commission, civil or military, persons who had taken a degree in the liberal arts, and persons adopted by gentlemen, were considered entitled to this rank, which has now been long obsolete as a distinction.

Gentleman Usher of the Black Rod.

An officer belonging to the Garter, whose duty it is to attend the House of Lords during the sessions of parliament, and to carry messages to the House of Commons.

Gentlemen-at-Arms. A corps of forty gentlemen whose duties are to attend the sovereign on state occasions. The corps was established by Henry VIII. in 1509, under the name of 'The Band of Gentlemen Pensioners.' It consisted entirely of men of noble blood, and was called *His Majesty's Honourable Corps of Gentlemen-at-Arms* by William IV. in 1834, and is now recruited entirely from retired army officers.

Gentles. The maggots or apodal larvæ of the flesh fly (*Musca carnaria*), and other Diptera, are sometimes so called.

Genus (Lat.). In Logic, one of the predicables, which is considered as the material part of the *species* of which it is affirmed. [Logic; PREDICABLE.]

GENUS. In Music, the general name for any scale of music. If a scale proceed by tones, it is called the *diatonic* genus; if between the tones semitones are introduced, it is called the *chromatic* genus. When the subdivisions are smaller, as quarter tones, it is called the *enharmonic* genus.

GENUS. In Natural History, that distinct but subordinate group of animals and plants which gives its name as a prefix to that of all the species of which it is composed.

Geocentric (Gr. γῆ, earth, and κέντρον, centre). A term frequently used in Astronomy, signifying literally *having the earth for its centre*. The apparent motion of any planet, as seen from the earth, is called its *geocentric motion*. The *geocentric latitude* of a planet is the angle formed by a straight line, supposed to be drawn from the planet to the earth, with the plane of the earth's orbit or the plane of the ecliptic. *Geocentric longitude* of a planet is the angle at the earth formed by two straight lines, one of which is drawn to the first point of Aries, and the other to that point of the ecliptic which is intersected by a perpendicular circle, the plane of which passes through the earth and planet. *Geocentric* is opposed to *heliocentric*, which refers to the centre of the sun. These terms are used only in speaking of bodies belonging to the solar system. The fixed stars are at such prodigious distances, that they are referred to the same points in space, whether we consider them as seen from the earth or the sun.

Geodes (Gr. γᾰῶδης, earthy). Hollow nodules the interior of which is frequently lined with crystals of Quartz, Calc Spar, &c. Bodies

GEODESY

of this kind are of frequent occurrence in the New Red Marls of Somersetshire and Gloucestershire, where they commonly go by the name of *Potato-Stones*.

Geodesic Curvature. [CURVATURE, GEODESIC.]

Geodesic Line. In Geometry, a curve traced on a surface, so that its osculating plane at every point contains the normal to the surface at that point. A *geodesic* may also be defined as the curve which a string, lying on the surface, would assume if subjected to tension at its extremities. From this definition it follows that a geodesic must, under ordinary circumstances, be the shortest line that can be drawn on the surface between any two of its points. The geodesics on a sphere are its great circles; the geodesics on a developable surface become, of course, right lines when the surface is unfolded into a plane. The geodesics on an ellipsoid have very beautiful properties; as an example, we may mention the theorem discovered by Prof. Roberts of Dublin (*Liouville's Journal*, vol. ii. 1846), according to which the sum (or difference) of the two geodesics joining any point of a line of curvature to two umbilics is constant. Every surface may be said to have a geometry of its own in which geodesics correspond to right lines on a plane. On the ellipsoid, therefore, the lines of curvature correspond to plane conics. The geodesics on a quadric surface are examined at some length in Salmon's *Analytical Geometry of Three Dimensions*; and interesting general properties of geodesics will be found in Gauss' *Disquisitiones generales circa Superficies Curvas*, as well as in the notes to Liouville's edition of Monge's *Application de l'Analyse à la Géométrie*, in which this memoir of Gauss' is reprinted. The differential equations of a geodesic are easily deduced from the first definition. If $u=0$ be the equation of the surface, and s denote an arc of a geodesic, we have

$$\frac{d \frac{dx}{ds}}{du} = \frac{d \frac{dy}{ds}}{du} = \frac{d \frac{dz}{ds}}{du}.$$

Geodesy (Gr. γεωδαισία, from γῆ, and δαίω, I divide). This term signifies literally *the division of the earth*, in which sense it is synonymous with land surveying; but it is usually employed in a more general sense to denote that part of practical geometry which has for its object the determination of the magnitude and figure either of the whole earth, or of any given portion of its surface. In this sense it comprehends all the geometrical or trigonometrical operations that are necessary for constructing a map of a country, measuring the lengths of degrees, &c. In order to construct an accurate map, or determine the form and dimensions of a country, it is necessary, in the first place, to determine the absolute distances between the several stations or points; secondly, to determine the azimuths of the lines thus measured, that is

their situation with respect to the meridian; and thirdly, the differences of latitude and longitude of the stations. The operations necessary for determining the absolute distances, comprehending the measurement of a base, the observation of angles, the computation of the sides of the triangles, and their reduction to the same level, are called the *geodesical* or *geodetical* operations; while those which are required for determining azimuths and latitudes are called the *astronomical* operations. The determination of the figure and dimensions of the earth is a problem of very great importance to astronomy and geography, and has accordingly at all times been a subject of much interest to mathematicians; but it is only since the middle of the last century that operations on an adequate scale for its solution have been undertaken in different parts of the world. For the results of the more important of these operations, see *DIGREE*.

Geognosy. [*GEOLOGY*.]

Geography (Gr. *γεωγραφία*, from *γη*, and *γραφω*, *I describe*). The description of the earth. The subjects comprehended in the science of Geography are usually arranged under three great divisions—*ASTRONOMICAL*, *PHYSICAL*, and *POLITICAL GEOGRAPHY*.

GEOGRAPHY, ASTRONOMICAL.—This division of geography has for its object the determination of the form and dimensions of the earth and its relations with the celestial bodies.

In order to describe the earth, the first point to be ascertained is its general form. That the surface of the earth is convex, is apparent from the phenomena presented by the gradual coming on of day and night, and the displacement of the stars in proceeding towards the north or south; for if the earth were flat, the sun, in appearing above the horizon, would illumine the whole of its surface at the same instant; and on the supposition of its being either flat or cylindrical, the pole star would maintain the same elevation, whereas to the traveller who advances northward it gradually appears more elevated, and to him who advances southward more depressed. All these appearances are observed in the same manner on whatever part of the earth we are placed; and from them alone the globular form of the earth might be inferred, even if the fact had not been placed beyond doubt by the voyages of circumnavigators. Astronomers in modern times have indeed discovered that it is not a perfect sphere, being flattened in a slight degree at two opposite points (which are the poles of rotation); but the deviation from perfect sphericity is so small, that for all the purposes with which geography is concerned it may be neglected without sensible error. [*FIGURE OF THE EARTH.*]

In order to determine the relative positions of points on a sphere in the most commodious manner, mathematicians refer them to two *great circles*; that is to say, circles formed by the intersection of the surface of the sphere by a plane passing through its centre. The earth is

a body which revolves about an *axis* of rotation; the position of this axis, therefore, with respect to the celestial constellations, determines one great circle, namely, the *equator*, or the circle which is equally distant from the two poles of rotation and divides the globe into two opposite hemispheres. The equator, therefore, being marked out by nature, or by the apparent revolutions of the celestial bodies arising from the real diurnal rotation of the earth, is a circle to which all places are most conveniently referred: and it has this property, that it never undergoes any change of place on the sphere; for astronomers have proved that since the date of the earliest observations, the poles of rotation, and consequently the equator, have always maintained the same invariable position on the earth's surface.

The distance of a place from the equator cannot be directly measured; but by means of astronomical observations we can determine that distance in aliquot parts of the earth's circumference, that is in degrees of a great circle. It is not, however, sufficient to know how many degrees a place is distant from the equator. It is necessary, also, in order to distinguish it from all other places, to know how it is situated with respect to a certain *meridian*, or great circle perpendicular to the equator, and consequently passing through the poles. In reference to the diurnal rotation of the earth, all meridians are in precisely the same circumstances; the choice is consequently entirely arbitrary, and geographers, as well as astronomers, generally select that which passes through the capital of their own country as the circle to which they refer all other places. The equator and the assumed meridian thus form the coordinates of the sphere. The distance of any place from the equator, measured on the arc of the meridian, is the *latitude* of the place; its distance from the assumed meridian, measured on a circle parallel to the equator, is its *longitude*; and when the latitude and longitude of any place are both known, the position of the place itself is entirely determined. The latitude of a place is ascertained by observing the height of the pole above the horizon of that place; and the longitude of one place in respect of another, by the interval of time which elapses between the passage of any celestial body over their respective meridians. [*LATITUDE AND LONGITUDE.*]

Besides the rotatory motion about its axis, the earth has also a motion of revolution about the sun, which is completed in the course of one year. The first of these motions causes the succession of day and night; the second the vicissitudes of the seasons, and the inequality of the length of the natural days. These two last phenomena depend on two circumstances: first, that the axis of the earth is not perpendicular to the plane of the ecliptic, or the plane in which the annual revolution is performed; and second, that the extremities of this axis, or the two poles of rotation, continue to be directed to the same points of the celestial sphere during

GEOGRAPHY

the whole time of the revolution. Hence it follows that the plane of the equator, though invariable in respect of absolute space, is continually changing its position in respect of the sun; and the apparent effect is the same as if the sun

had a vibratory motion in the heavens, rising above the plane of the equator $E E$ one half of the year, and falling below it, during the other half. When the sun is in the equator at S , the two poles of the earth n and s are in the great circle which divides the illuminated from the dark hemisphere. When the sun reaches his greatest northern declination at S' , the illuminated hemisphere is $a E a'$, and the north pole n comes considerably within it. On the other hand, when the sun's declination is south, as at S'' , the south pole s comes into the illuminated hemisphere, while n is left in darkness. When the sun is at S , his apparent diurnal motion is performed in the equator, and the days and nights are of equal length all over the world. The angle which the planes of the equator and ecliptic make with each other is about $23\frac{1}{2}^\circ$; consequently, since the greatest declination of the sun from the equator is the same quantity, it must happen that at midsummer the sun is $23\frac{1}{2}^\circ$ to the north of the equator, and at midwinter $23\frac{1}{2}^\circ$ to the south of it. The inequality of the natural days is an immediate consequence of the sun's declination: for as the solar rays come to the earth nearly parallel, one half of the globe must always be illuminated at once, and the other half in darkness; consequently when the sun declines $23\frac{1}{2}^\circ$ to the north of the equator, all that part of the earth which is within $23\frac{1}{2}^\circ$ of the north pole will remain, while the earth performs its diurnal revolution, within the illuminated hemisphere. A small circle of the sphere parallel to the equator, and at the distance of $23\frac{1}{2}^\circ$ from the pole, is called the *polar circle*; and at this latitude the sun, when at his greatest declination, comes exactly to the horizon at midnight, without setting; consequently the length of the longest day is twenty-four hours. At the equator the length of the day is always twelve hours; and from the equator to the polar circle the length of the longest day increases with the increase of latitude; and from the polar circle to the pole the length of time during which the sun continues above the horizon without setting increases with the latitude from twenty-four hours to six months. The two small circles of the sphere parallel to the equator, which limit the sun's greatest declination, are called the *tropics*; and the whole surface of the globe is divided by the two tropics, and the two polar circles, into five *zones* or spaces; namely, the *torrid zone*, which is included between the two tropics, or extends $23\frac{1}{2}^\circ$ on either side of the equator; the two *temperate zones*, or the spaces included between the tropic and polar circle in each hemisphere; and the two *frigid zones*, or the spaces between the

poles and their respective polar circles. These may be called the astronomical divisions of the globe, as they depend on the position of the earth's axis of rotation with respect to the plane of its orbit, and are determined by astronomical observations.

GEOGRAPHY, PHYSICAL.—Has for its object the description of the principal features of the earth's surface, as consisting of land and water; the extent and configuration of the continents and islands; the elevation and direction of the mountain chains; the conformation of the plains and valleys; their altitude above the level of the sea; the soil, climate, and animal and vegetable productions of different countries. It embraces also the various phenomena of the ocean, which may be classed under the term **HYDROLOGY**; the depth of the sea, and the inequalities of its depth, its saltness and temperature; the direction and velocity of currents, the tides, the polar ice, &c. In like manner it comprehends also many of the questions which are usually treated under the terms **METEOROLOGY** and **CLIMATE**; the mean temperature of different countries; the height of the snow-line; the prevailing winds; the barometric pressure; the quantity of annual rain, of evaporation, &c.; and the effect of all these circumstances on the condition of the human race.

On casting our eye on a globe or map, we immediately perceive the very unequal distribution of land and water on the surface of the earth. The land occupies a very little more than one-third of the whole surface, and the water all the remaining portion. Nor is the inequality of the distribution in respect of the two hemispheres less remarkable. Of the whole land about four-fifths is situated in the northern hemisphere, and the remaining one-fifth in the southern. In a general view, the land consists of three great masses: the *old continent*, which comprehends Europe, Asia and Africa; the *new continent*, or America; and *New Holland*—which are separated from each other by the great oceans. The general features of the two continents differ remarkably. In the old continent the general direction of the land, and of the great mountain chains, is from west to east almost parallel to the equator; while in America the general direction is from north to south, along the meridian. Thus the four great systems of mountain ranges in Asia—namely, the Altai, the Thian-shan, the Kuen-lun, and the Himalaya—all stretch from west to east; and the Andes, which extends from one extremity of America to the other, ranges at right angles to this direction from north to south. Another striking feature of the land is, that all the great peninsulas are pointed to the south pole. This is the case with South America, Africa, Arabia, Hindustan, Malaya, Cambodia, the Corea, Kamtschatka, California, Alaska, Greenland, Florida, Italy, &c.; in short, the only two exceptions are Yucatan in the gulf of Mexico, and Jutland in the German Sea, which

GEOLOGY

are both formed of alluvial land, and may therefore be supposed to owe their formation to partial influences which have not operated on the great continental masses. This similarity of disposition can only be attributed to the agency of some mechanical cause; and the phenomena strongly suggest the idea of the terraqueous masses having been shaped into their existing forms by the action of a great wave or current flowing from the southern to the northern pole. [ATMOSPHERE; CLIMATE; GEOLOGY; TIDES; WIND; &c. See also an excellent article on the general subject by Dr. Traill in the *Encyclopædia Britannica*.]

GEOGRAPHY, POLITICAL.—Wherever the natural features of portions of the globe lead, or seem to lead, to characteristic political phenomena, geography may help to interpret the laws of this branch of practical science. For instance, the peculiar configuration of Greece was cited in ancient times as suggestive of those municipal constitutions which belonged in an eminent degree to its political system, and which developed or aided in so marked a manner the peculiar intellectual capacity of its former inhabitants. Similarly, the physical features of the central part of the North American continent have constantly been cited as necessitating the adoption and maintenance of federal institutions. Again, the geographical position of the British Islands may be fairly understood to contribute, in no small degree, to the great commercial importance which they have achieved.

Political geography is closely related to statistics, and supplies, indeed, the principles for which statistics supply facts. It need hardly be said, however, that there is a strong tendency towards hasty generalisation from statistics, and towards rash inductions from geography. The danger is the greater in the latter case, for the obvious reason that though societies are largely influenced by external circumstances, they may nevertheless adapt themselves to them, and will be greatly controlled by antecedent facts. For instance, any argument adverse to the possible organisation of a united political system in the Italian peninsula, if gathered from its mediæval history, might be a fallacy similar to that which led the first Napoleon to call Italy a mere geographical expression. [STATISTICS.]

Geology (Gr. *γη*, earth, and *λόγος*). The science which treats of the earth's history, of the causes that have produced change in the materials of the earth's crust, of the successive changes that have taken place in the organic and inorganic kingdoms of nature, of the influence of these changes in modifying the materials, and of the nature and various conditions of rocks and their contents.

Geology proper is either, 1. **DESCRIPTIVE GEOLOGY**; 2. **PHYSICAL GEOLOGY**; or 3. **PRAC- TICAL GEOLOGY**. Physical Geology is too incomplete to admit of distinct notice. The other departments are treated under their respective headings.

A rational history of the world may be said to have originated with Aristotle, who carefully observed the changes going on upon the earth, and referred various phenomena to similar causes of change. In the twelfth chapter of the *Meteorics* he observes that the distribution of land and sea, in particular regions, does not endure through all time, but that sea covers ancient land, and land now exists where there was once sea. He adds, 'There is reason for thinking that these changes take place according to a certain system and within a certain period.'

After Aristotle, Strabo speculated with singular judgment and profoundness on the causes suggested to explain the frequent occurrence of marine shells where the sea has never been known to reach in modern times. He accounts for them by assuming that the same land is sometimes raised up and sometimes depressed, the sea being also simultaneously raised and depressed. 'It is proper,' he concludes, 'to derive our explanations from things which are obvious and in some measure of daily occurrence, such as deluges, earthquakes, and volcanic eruptions, and sudden swellings of the land beneath the sea.'

Although, then, before the Christian era and for many centuries afterwards there was no very clear comparison of facts relating to the earth's history, there were sensible and useful suggestions, and a sound basis of philosophy. There is, however, no proof of research in this department of science during the middle ages, nor did geological phenomena again attract attention till the beginning of the sixteenth century.

The origin of fossils was the first subject of enquiry, and the north of Italy the place of discussion. To Fraacastoro, in 1520, is due the credit of having clearly put forward the only rational explanation. It was long, however, before this was admitted, and another century elapsed during which the subject was still under discussion. Even so lately as in 1670 it was necessary seriously to controvert the notion that fossils were due to accidental causes, or, in other words, were *lusus nature*, 'tricks of nature.'

During the whole of the eighteenth century, the progress of geology proper was irregular. Already before the commencement of that period, Lister had intimated that many fossils belonged to extinct species, and Leibnitz had theorised on the result of repeated invasions of the sea. Ray also had enlarged on the effects of running water, and Woodward had made those collections which show how closely he observed. It was not till 1760 that any more rational views than those of the physico-theologists were advanced; but from that time commenced the publication of a series of special descriptions which ultimately led to the establishment of the doctrines at present held. The battles between the Neptunists and Vulcanists then raged, and continued to distract the attention of those who would otherwise perhaps have devoted themselves to the study of facts.

GEOMANCY

At last, in 1790, appeared the 'tabular view' of William Smith, a contribution far more important than might at first appear, inasmuch as it laid the foundation of that great series of observations on which all progress of the science has since rested. Leaving the advocates of Werner and Hutton to fight in words, the Geological Society of London was soon afterwards founded for the purpose of obtaining and publishing positive knowledge. This and other societies that have succeeded it, and the labours of many eminent individuals, have at length placed the science on its proper basis. The present state and modern discoveries in geology will be noticed in other articles. They are the result of a large amount of patient investigation, and include a variety of facts in various departments of science. The conclusions and theories of modern geologists are generally put forward with a sounder basis of facts, and less reference to merely speculative views, than was formerly the case; but there is still much tendency among a large class of writers to mix up other enquiries and introduce foregone conclusions even when treating of questions of pure geological science.

The progress of discovery in geology for many years past has been much governed by the advance of PALÆONTOLOGY. Fossils are regarded as characteristic of formations; and by a careful knowledge and comparison of groups of fossils, all the principal groups of strata in different countries, or different parts of the same country, can alone be clearly identified as contemporaneous. As, however, only certain parts of plants and animals are generally preserved in a fossil state, and these are not always the most important for determining species, it is evident that a very limited number of natural groups are available. In botany especially, as the comparison of species is uncertain and difficult without all the floral and germinating parts, the mere fragments of leaves and wood usually found are of little value. In zoology it is only the shells and cases of many animals that remain, while very many large groups of soft animals without skeletons are never indicated at all. Even of the higher animals, as the vertebrata, the skeletons of fishes, a few detached bones of birds, and bones of reptiles and quadrupeds, must form the basis for all investigations. Thus geological discovery is unable to advance so rapidly as might be expected from the varied nature of the observations. [See DESCRIPTIVE GEOLOGY; ECONOMIC GEOLOGY; ENGINEERING GEOLOGY; ROCKS; CLASSIFICATION; PALÆONTOLOGY, and the articles referred to under these headings.]

Geomancy (Gr. *γῆ*, earth, and *μαντεία*, prophecy). Divination by points or circles made on the earth. It was termed by old writers 'a part of natural magic, the daughter and abbreviation of astrology.' Geomancy was among the acts of divination most sedulously cultivated by professors of that science in the fifteenth and sixteenth centuries. Nativities were cast, fortunes predicted, and oracular

GEOMETRY

obtained to questions, by the inspection of certain combinations of lines and figures representing the conjunctions of the planets, &c. [ASTROLOGY.]

Geometrical Mean. The second term of a geometrical progression consisting of three terms, or the second of three continued proportionals. In the case of two numbers, it is easily shown to be equal to the square root of their product. Any number of terms inserted between two given terms, so that the whole may form a geometrical progression, are said to be geometric means between those two. The celebrated *Dulian problem* reduces itself to the insertion of two geometric means between given extremes. [DUPLICATION OF THE CUBE.]

Geometrical. The meaning of this adjective as opposed to *algebraical* is sufficiently obvious; when applied to a construction, however, it has a more technical signification. The ancient geometers admitted only two instruments: the straight line and the circle. Every construction which required the use of any other curve or instrument, they called *mechanical* as opposed to *geometrical*.

Geometrical Progression. A series of numbers, each of which is obtained from the preceding one by multiplication by a constant number called the common ratio. According as the latter is greater or less than unity, the progression will be an increasing or decreasing one. If, generally, a_n denote the n^{th} term of a geometrical progression whose common ratio is r , and s_n denote the sum of the first n terms, we have $a_n = a_1 r^{n-1}$ and

$$s_n = a_1 \frac{1-r^n}{1-r},$$

two equations which embrace the whole theory of geometrical progression. From them any two of the five elements a_1 , a_n , r , n , and s_n , can, theoretically, be found when the remaining three are given. When r is positive and less than unity, the term r^n in the numerator of s_n becomes of less importance, the greater the value of n ; that is to say, the sum of the series is always less than $\frac{a_1}{1-r}$, but approaches more

and more to this limit, the greater the number of terms; $s_\infty = \frac{a_1}{1-r}$ is accordingly said to be

the sum of the infinite geometrical progression, whose first term is a_1 , and ratio r .

Geometry (Gr. *γεωμετρία*, from *γῆ*, earth, and *μέτρον*, measure). The science which treats of the properties of figured space. The etymology of the term suggests the object to which geometry was first applied, viz. the measurement of land. It is pretended that the science was invented in Egypt, where the annual overflowing of the waters of the Nile obliterated the landmarks, and rendered it necessary to have recourse to measurement in order to ascertain the proper allotment of each individual; but whatever may have been the origin of the

GEOMETRY

term, the occasions on which it is necessary to compare things with one another in respect of their forms and magnitudes are so numerous in every stage of society, that a geometry more or less perfect must have existed since the first dawn of civilisation. In geometry, bodies are considered only in reference to the properties of extension or magnitude, figure, and divisibility. Every body occupies an indefinite space, a certain determinate place, or finite portion of space, which is called its *volume*. The limits or boundaries which distinguish the place of the body, and separate it from the surrounding space, are called *surfaces*; a surface is therefore common to the two portions of space which it separates. As the limitation of space gives rise to the idea of surface, so the limitation of surface produces *lines*, a line being the boundary of a surface, or the place in which two surfaces intersect each other, and therefore common to both. In like manner the limitation of a line, or the intersection of two lines, produces a *point*. But a point marks only position, and has no properties. A line has length; a surface length and breadth; and a volume length, breadth, and thickness. Hence the properties of lines, the properties of surfaces, and the properties of volumes or solids, comprehend the objects of geometry.

From Egypt the science of Geometry is said to have been transported into Greece by Thales; but the assertions on which this supposition is grounded are utterly rejected by Sir G. Cornewall Lewis (*Astronomy of the Ancients*). The celebrated proposition of the square of the hypothenuse was the discovery of Pythagoras. Anaxagoras of Clazomene composed a treatise on the quadrature of the circle; and Plato had certainly made considerable advances in the science, as is proved by the simple and elegant solution which he gave of the duplication of the cube. About fifty years after the time of Plato, Euclid collected the propositions which had been discovered by his predecessors, and formed of them his famous *Elements*; a work which, in England, is still regarded by many as the best introduction to the mathematical sciences. It consists of fifteen books, of which thirteen are known to have been written by Euclid; but the fourteenth and fifteenth are supposed to have been added by Hypsicles of Alexandria. Apollonius of Perga, about 250 years B.C., composed a treatise on the *conic sections*, in eight books; and he is said to have been the first who applied to those curves the appellations by which they have ever since been distinguished—namely, the *parabola*, the *ellipse*, and the *hyperbola*. [CONIC SECTIONS.] About the same time flourished Archimedes, the most illustrious of the ancient philosophers. He distinguished himself in geometry by the discovery of the beautiful relations between the sphere and cylinder, by his work on *conoids* and *spheroids*, by his discovery of the exact quadrature of the parabola, and of the approximate rectification of the circle. In the list of names which

have come down to our times in connection with geometry, we may mention Eudoxus, Archytas, Eratosthenes, Aristarchus, Dinostratus, and Nicomedes; but for an account of the discoveries or inventions by which they are individually celebrated, we must refer to Montucla's *Histoire des Mathématiques*. The school of Alexandria produced Pappus and Diophantus; but the Greek geometry, though it was afterwards enriched by many new theorems, may be said to have reached its limits in the hands of Archimedes and Apollonius; and a long interval of seventeen centuries elapsed before this limit was passed. In 1637, Descartes published his *Geometry*; a work which will ever be remarkable, as containing the first systematic application of algebra to the solution of geometrical propositions. Soon after this followed the discovery of the *infinitesimal calculus*; and from that time to the present geometry has shared in the general progress of all the mathematical sciences. Besides Montucla's work, Chasles' *Aperçu Historique* (Brussels 1837) may be consulted with advantage with respect to the origin and development of geometrical methods. Of the works on Ancient Geometry, the following may be mentioned: Euclid, *Elements of Geometry*, and *Book of Data*; Apollonius, *Conics*; Archimedes, *Opera*; Pappus, *Mathematicæ Collectiones*; Vieta, *Opera Mathematica*; Huygens, *Opera*; R. Simson, *Opera Reliqua* and *Loci Plani*; Stewart, *Propositiones Geometricæ*; T. Simpson, *Elements of Geometry*; Legendre, *Elements of Geometry*; Leslie, *Elements of Geometry*, &c. For an account of the numerous editions of Euclid's *Elements* (which have been translated into every European language), see Murhard, *Bibliotheca Mathematica*; but to the list contained in that work should be added the more recent edition of Peyrard, in Greek, Latin, and French (Paris 1814). An edition of the first six books, in Greek and Latin, by Camerer and Hauber (Berlin 1824), also deserves to be noticed, on account of the valuable notes with which it is accompanied.

The modern works on Algebraic or Coordinate Geometry are very numerous: we can only mention those of Plücker, *Analyt. Geom. Entwicklungen* 1828–31, *System der Analyt. Geom.* 1835 and 1852, *Theorie der Algebraische Curven* 1839, and Möbius' *Barycentrische Calcul* 1827, as having marked an epoch in the history of the science, and Salmon's *Conic Sections* 1863, *Higher Plane Curves* 1852, and *Anal. Geom. of Three Dimensions* 1862, as treating the subject from the most modern point of view.

The modern works on *pure*, as distinguished from *coordinate* Geometry, are less numerous. Poncelet's *Traité des Propriétés Projectives des Figures*, Paris 1822; Steiner's *Systematische Entwicklung der Abhängigkeit Geometrischer Gestalten*, Berlin 1832, and his *Geometrischen Constructionen*, 1833; Chasles' *Cours de Géométrie Supérieure*, Paris 1847, and his *Traité des Sections Coniques*, 1864;

GEPONICA

Cremona's *Thoria Geometrica delle Curve Piane*, Bologna 1862; Mulcahy's *Modern Geometry*, 1864; and Townsend's *Modern Geometry of the Point, Line, and Circle*; may be mentioned as the most important and useful.

Geponica (Gr. *γεπονικός*, from *γη*, the earth, and *πόνος*, labour). The name of a Greek compilation of precepts on rural economy, extracted from ancient writers. The name of the compiler is unknown; but the authorities which he quotes are numerous, and deservedly celebrated. (Niclas's edition, 4 vols. 8vo. Leipsic 1781.)

Georama (Gr. *γη*, and *σφαῖρα*, I see). A name given to a large concave globe, or spherical chamber, having the features of the earth delineated on the concave surface, like the large globe exhibited for many years in Leicester Square. A spectator in the interior of such a globe sees a much larger portion of the surface at once than if he occupied an exterior position.

Georgics (Gr. *τὰ γεωργικά*, things pertaining to husbandry). The title of a poem by Virgil, in four books, on agriculture, and the care of cattle, bees, &c. It is considered by critics the most perfect of his works.

Georgium Sidus. [URANUS.]

Geothermometer. An instrument for measuring the earth's heat at different depths, as in wells and mines, and for determining its rate of increase with the depth. The temperature rises about one degree of Fahrenheit's scale for every seventy or eighty feet of descent; hence the inference that at the depth of a few miles the earth must be incandescent. [GLACIÈRES.]

Geraniaceæ (Geranium, one of the genera). A natural order of herbaceous or shrubby Exogens, representing the Geranial alliance, growing in most parts of the world, and nearly related to *Oxalidaceæ*, *Balsaminaceæ*, and *Tropæolaceæ*, with which they are by some botanists associated. They are distinguished by the peculiar dehiscence of their fruit, which consists of several carpels combined round a beaked torus, by the tumid joints of their stem, and by their stipulate leaves. Their sensible properties consist in an astringent principle, and an aromatic or resinous flavour. Many of them, especially those of the genus *Pelargonium*, are beautiful objects, and much cultivated in gardens.

Geranium, Oil of. A name given by perfumers to the essential oil of an andropogon. [GRASS OIL.]

Germ-cell. In Physiology, the cell which results from the union of the spermatozoon, or spermatie matter conveyed by it, with the germinal vesicle, or its nucleus. The germ-cell assimilates the surrounding yolk and propagates its kind by spontaneous fission, whence the first or parent-cell has been termed the *primary germ-cell*, and its progeny the *derivative germ-cells*.

Germ-mass. In Physiology, the materials prepared for the future formation of the

GERMINAL AREA

embryo, consisting of the derivative germ-cells and the yolk which they have assimilated.

Germ-yolk. In Physiology, that portion of the primary yolk of the egg which is to be assimilated by the derivative germ-cells in the formation of the germ-mass. In some animals the whole yolk is so assimilated; in others, as e.g. the bird, only a very small portion; that, viz., which is included in the germ-mass or *cicatricula*.

German School. In Painting. In this school we find an attention to individual nature, as usually seen, without attempt at selection or any notion of ideal beauty. The early German painters seem to have set a particular value on high finishing, rather than on a good arrangement and disposition of the subject. Their colouring is far better than their drawing, but their draperies are generally in bad taste. Though among the painters of this school there are some who do not deserve this censure, they are not sufficient in number to change the general judgment that must be passed upon it. Wohlgenuth, Martin Schoen, Holbein, and Albert Dürer are the heads of it. Martin Schaffner, Aldegrever, Amberger, and Lucas Cranach were also masters of ability, but utterly void of taste. So were also the later masters who pursued their studies in Italy, as Golzius, and Spranger, Heintz and Van Aachen. The later masters of the seventeenth century gave more attention to nature, but of them few have handed down their names to our times, with the exception of John Rottenhammer, Adam Elzheimer, and Balthasar Denner. Compared with Italy, Spain, and France, the German school has never emerged from mediocrity. These remarks do not apply to the school now rising in Germany, which (with such leaders as Overbeck, Cornelius, Schnorr, Hess, and Kaulbach, and other still more sentimental masters of the school of Düsseldorf, now deservedly renowned both for its oil and its fresco painters) seems likely to put the German school of painting on a level with its great intellectual powers in other branches of art and science, though the German artists do not yet display the masterly powers of execution developed by the modern painters of France. In enumerating the artists of Germany of the present century, the highest praise is due to their best landscape painters, many of whom are unsurpassed by those of any other country.

German Silver. A silver-like alloy generally composed of nickel, copper, and zinc; various proportions are given, amongst which the following are said to be the best: 1 nickel, 1 zinc, 2 copper; and 8 nickel, 3½ zinc, 8 copper. It resembles the tutenag of the Chinese.

Germen (Lat. *a bud*). In Botany, the organ commonly called the *ovarium* or ovary.

Germinal Area. In Physiology, the circular or oval space formed by liquefaction and metamorphosis of a peripheral portion of the

GERMINAL MEMBRANE

germ-mass, preparatory to the appearance of the first trace of the proper embryo. It is divided into a central clear part called *area pellucida*, and a peripheral part called *area opaca*; the portion of the latter in which blood and blood-vessels are developed is called the *area vasculosa*.

Germinial Membrane. In Physiology, the strata of cells and nuclei of cells originally forming, and afterwards extending from, the germinal area: the external stratum is the *vertebral* layer, also called the *serous* and *animal* layer; the internal stratum is the *visceral* layer, also called the *mucous* and *vegetal* layer.

Germinial Spot. In Physiology, the nucleus of the germinal vesicle: it consists of a finely granulated substance, strongly refracting the rays of light.

Germinial Vesicle. In Physiology, a clear nucleated cell, which is the first formed and most essential part of the ovum: it is surrounded by the yolk, and passes to the periphery of that part prior to impregnation, after which the germinal vesicle becomes opaque, or disappears. It is sometimes called, after its discoverer, the *Purkiningian vesicle*.

Germination (Lat. *germinatio*, from *germen*). The process by which a plant is produced from a seed. The phenomena of germination are best observed in dicotyledonous seeds; such, for instance, as the bean, pea, lupin, &c. These seeds consist of two lobes or cotyledons, enveloped in a common membrane; when this is removed, a small projecting body is seen, which is that part of the *germ* which afterwards becomes the root, and is termed the *radicle*: the other portion of the germ is seen on carefully separating the cotyledons, and is termed the *plumule*; it afterwards forms the stem and leaves. When the ripe seed is removed from the parent plant it gradually dries, and may be kept often for an indefinite period without undergoing any change; but if placed under circumstances favourable to its germination, it soon begins to grow: these requisite circumstances are a due temperature, moisture, and the presence of air. Where these are present, the seed gradually swells, its membranes burst, and the germ expands. The root is at first most rapidly developed, the materials for its growth being derived from the cotyledons; and when it shoots out its fibres or rootlets, these absorb nourishment from the soil, and the plumula is developed, rising upwards in a contrary direction to the root, and expanding into stem and leaves. For this growth the presence of air is requisite; if it be carefully excluded, though there be heat and moisture, yet the seed will not vegetate. Hence it is that seeds buried very deep in the earth, or in a stiff clay, remain inert; but, on admission of air by turning up the soil, begin to shoot forth. From experiments which have been made upon the germination of seeds in confined atmospheres, it appears that carbonic acid is evolved, and that part of the starch of the cotyledons

GERMINATION

passes into gum and sugar; so that most seeds, as we see in the conversion of barley into malt, become sweet during germination. Light is injurious to the growth of a seed. It is, therefore, obvious that the different requisites for germination are attained by placing a seed under the surface of the soil warmed by the sun's rays, where it is moistened by its humidity and by occasional showers, and excluded from light, but within reach of the access of air. The most favourable temperature is between 60° and 80°; at the freezing point none of the more perfect seeds vegetate; and at temperatures above 100° the young germ is usually injured.

When the young plant is perfected, the cotyledons, if not converted into leaves, rot away, and the process of nutrition is carried on by the root and leaves. The principal nourishment is taken up from the soil by the root, and chiefly by its small and extreme fibres; so that when these are injured or torn, as by careless transplantation, the plant or tree generally dies. The matters absorbed, consisting of water holding small portions of saline substances and of organic matter in solution, become the *sap* of the plant; and this is propelled upwards in the vessels of the stem, or of the outer layer of wood, into the leaves; here it is exposed to the agency of air and light: it transpires moisture, and occasionally carbonic acid. But the leaves also at times absorb moisture, and during the influence of light they decompose carbonic acid, and, retaining the carbon, evolve oxygen; the sap thus becomes modified in its composition, and the characteristic proximate principles of the vegetable are formed. These return in appropriate vessels from the leaves, chiefly to the inner bark, where we accordingly find the accumulation of the peculiar products of the plant: they also enable it annually to form a new layer of wood. Hence it is that the transverse section of the wood exhibits as many distinct zones as the tree is years old. We are ignorant of the causes of this circulation of the sap; but that it follows the course which has been stated is proved by the operation which gardeners call *ringing*, and which they sometimes resort to, to make a barren branch bear flowers and fruit: it consists in cutting out and removing a circular ring of bark, so as to prevent the return of the sap by the descending vessels, which at first ooze copiously; but afterwards the wound heals, and the juices are accumulated in all parts above the extirpated ring, producing tumefaction in the limb, and often inducing a crop of flowers and fruit, or causing them to appear earlier than on the uncut branches. If a tree be wounded so as to cut into the central portions of the wood, or the outer layer of new wood, the flow of ascending sap is then seen to take place upon the lower section, where are the vessels that carry it up to the leaves; and the flow of descending sap is principally confined to the upper section of the inner bark, from which, after a time, new bark is produced, and the parts again become united.

GEROCOMIA

Gerocomia (a word coined from Gr. *γέρω*, old, and *κατέω*, I am concerned about). That part of medicine which relates to the diet and treatment of old age.

Gerund (Lat. *gerundium*). In Grammar, a term applied to the oblique cases of the neuter of the Latin participle passive in *us*, which serve as a declinable infinitive active and govern the case of their verbs.

Gerusia (Gr. *γερουσία*, an assembly of elders). In Ancient History, the senate of Sparta, the aristocratic element of Spartan polity. The number of this council was thirty, including the two kings; and the qualifications of its members were, pure Spartan blood, and an age not below sixty years. The election was performed in a primitive manner by acclamation, the candidates being brought forth one by one before the people. He who was greeted with the loudest applause was held to receive the highest honour next the throne. The functions of the *gerusia*, so far as they can be determined, were partly deliberative, partly judicial, and partly executive. It prepared measures which were to be laid before the popular assembly; it exercised a criminal jurisdiction, with power of capital punishment, and was also invested with a kind of censorial authority for the correction of abuses; but it is not likely that the ephors would permit any exercise of this authority which would interfere with their own. (Müller's *Dorians*.)

Geuth. [THANE.]

Gesneraceæ (Gesneria, one of the genera). A natural order of herbaceous Exogens, inhabiting the tropics, allied to *Bignoniaceæ*; from which it differs in the partly inferior one-celled ovary, apterous seeds, and habit; from *Cyrtandraceæ* in the one-celled ovary, simple placenta, and albuminous seeds; from *Scrophulariaceæ* by the same characters, with the exception of the seeds. The fruit, when succulent, is sometimes eatable, mucilaginous, and sweetish. Many beautiful species of *Gloxinia*, *Gesneria*, and *Sinningia* are known in our gardens. Botanists have generally united the *Cyrtandraceæ* with them as a sub-order. [CYRTANDRACEÆ.]

Gesture Language. The gesture language of savage tribes must be carefully distinguished from the alphabet in which the deaf and dumb are taught to converse by teachers who can speak. In the latter system, the signs represent letters or words: in the former, they directly represent ideas. Hence savages who are accustomed to converse by signs, can with ease communicate with deaf and dumb children in civilised countries. The imperfect spoken language of many tribes is still eked out by the help of this gesture language, which, in the belief of some recent writers on the subject, is the original utterance of mankind, out of which speech has developed itself more or less fully among different tribes. (Tylor's *Researches into the Early History of Mankind*.)

Gesum (coined from Gr. *γεῦω*, to give a relish). The Avens or Herb Bennett, *G. urba-*

Ghibellines

num, is a native plant of the Rosaceous order with lyrate pinnate leaves and small yellow flowers. Its root, called by the old herbalists Clove-root, has an aromatic clove-like odour, and possesses astringent properties. It was at one time put into ale to give it a clove-like flavour and prevent its turning sour, and has been recommended to be chewed by those who are troubled with foul breath.

Geysers (from an Icelandic word signifying *raging* or *roaring*). The celebrated spouting fountains of boiling water in Iceland. The Geysers are situated about thirty miles from the volcano Hecla, in plains full of hot springs and steaming fissures. Their jets are intermittent, and the height to which they rise appears to vary much at different times. Olafsen and Povelsen estimate that of the Great Geyser, when they saw it, at 550 feet. Few English travellers have seen it spout higher than 90 or 100 feet; but Mr. Henderson saw it reach 150 feet in 1815, and one of the smaller Geysers, when a stone was thrown into it, spouted to the height of 200 feet.

For the most recent views regarding the origin, duration, and ultimate extinction of the Geysers, see Professor Bunsen's 'Researches on the Volcanic Phenomena of Iceland,' and a lecture on the same subject by Professor Tyndall. (*Proceedings of the Royal Institution* 1853.) [SPRING, INTERMITTENT.]

Ghaunts. A term applied originally to the narrow and difficult passes in the mountains of Central Hindustan, but which has been gradually extended to the mountains themselves. They consist of two great chains extending along the east and west coasts of the Deccan, parallel to each other, or rather diverging, and leaving between them and the sea only a plain of forty or fifty miles in breadth. The precise altitude of these mountains has not been ascertained, but their general elevation is from 3,000 to 4,000 feet; and while the extent of the Eastern Ghaunts has been limited to a line of 300 miles, the chain of Western Ghaunts is said to extend without interruption nearly 1,000 miles. (Murray's *Encyclopædia of Geography*.)

Ghea Butter, also called **Galam**. A fat oil, closely resembling palm oil. It is the produce of a West African palm, the *Micadenia* or *Bassia Parkii*, is of a greyish-white colour, and melts at a temperature of 97° Fahr.

Ghebres. [GUEBRES.]

Ghee. A kind of butter used by the natives of India. It is prepared by boiling fresh-drawn milk in earthen pots for about an hour, and adding to it, when cooled, a little curdled milk, called *tyre*, to make it coagulate. It is afterwards churned, some hot water being added during the process. The smell and flavour are strong and coarse.

Ghibellines. In Italian History, the name of a political party, which maintained the supremacy of the German emperors over the Italian states, and their claims to investiture, &c., disputed by the popes. [GUELFES.]

GHOST, HOLY, ORDER OF THE

Ghost, Holy, Order of the. The principal military order of France under the old régime; instituted in 1574 by Henry III., for nobles only; abolished at the Revolution; reconstituted by the Bourbons.

Giant's Causeway. [BASALT.]

Giants (Gr. *γίγαντες*). In the Homeric mythology, the aboriginal inhabitants of Thrinakia, who for their impieties were extirpated by Eurymedon. (*Od.* vii. 59.) In Hesiod they are beings produced by the blood of Uranus (or heaven) falling upon Ge (the earth); by later writers they are frequently confused with the Titans. In Northern mythology, the Trolls, Frost Giants, &c. represent, like the Homeric *gigantes*, the original people of the land. See a learned and amusing article on this subject in the *Encyclopædia Metropolitana*.

Giaour (Turk. *a dog*). An epithet applied by the Turks to all, but more especially to Christians, who do not profess adherence to Mohammedanism.

Gib. The fixed iron wedge used in conjunction with the *cotter*, or movable one, for the purpose of wedging up the parts of machinery. It has several other meanings in mechanics; thus, the arm of a crane, which supports the weight and round which the movement takes place, is called a *gib*.

Gibbose (Lat. *gibbosus*, from *gibba*, *a hump*). Humped. When a surface presents one or more large elevations.

Gibbous (Lat. *gibbus*, *protuberant*). This term is applied in Astronomy to the swelling or convex appearance of the moon when more than half full or enlightened. In the telescope, the planets Mercury, Venus, and Mars exhibit a similar appearance.

Gibbsite. The native hydrated alumina of Massachusetts, named after Colonel Gibbs.

Giddiness. [SCOTODINIA.]

Gieseckite. A mineral discovered in Iceland and by Giesecke. It is a hydrated silicate of alumina and potash, and occurs in brownish hexagonal prisms.

Gift. In Law, in its general sense, a conveyance which passes either lands or goods. But when restricted to immovable property, it signifies in its proper sense the creation of an estate tail. [ESTATE TAIL.] At the present time, however, the term *gift*, even in legal documents, usually bears only its popular sense of a gratuitous donation of money or some other description of property.

Gig. A light carriage drawn by one horse. *Gigs* or *gig machines* are rotary cylinders covered with wire-teeth, for teasing woollen cloth.

Gro. In Naval Language, a light boat attached to a ship. It is rowed by two, four, or six alternate oars, and is ordinarily kept for the use of the officers.

Giga or **Jig** (Ital.). In Music, an air for dancing in triple time, usually $\frac{3}{8}$ or $\frac{12}{8}$.

Gigantomachia (Gr.). In Painting, representations of combats with or between giants. The term is more particularly applied to the conflicts waged between Jupiter and the giants. [GIANTS]

GILDING

The most remarkable work of this class is the 'Fall of the Giants' in the Palazzo del Té at Mantua, painted under the superintendence of Giulio Romano.

Gilbertines. A religious order founded by Gilbert of Sempringham, in Lincolnshire, in the twelfth century. It possessed about twenty-five houses in England at the time of the dissolution.

Gilbertite. A white micaceous mineral composed chiefly of silica, alumina, and lime, from St. Austel, in Cornwall, named by Dr. Thomson, after Mr. Davis Gilbert, formerly President of the Royal Society.

Gilding. The application of a superficial coat of gold on wood, metal, and other materials. The beauty and durability of gold render it the most valuable of all ornamental substances; but, on account of its weight and high price, its use in these respects would be greatly restricted, were it not the most extensible and divisible form of matter, so that it may be made to cover a larger surface than an equal quantity of any other body. Metals are usually covered with gold by various processes: one of these, called *water-gilding*, is now almost disused: it consisted in perfectly cleaning their surface, and then, in the case of silver, for instance, rubbing it over with a solution of gold in mercury, *amalgam of gold*: the vessel was then heated over a clear charcoal fire, by which the mercury was driven off, and the gold left adhering to the silver surface, upon which it was afterwards burnished. The surface of copper or brass was prepared by cleaning and rubbing it over with a solution of nitrate of mercury, which amalgamated the surface, and enabled the gold amalgam, when subsequently applied, to adhere; heating and burnishing were then resorted to as before. Brass and copper buttons were gilt in this way; the quantity of gold used being so small that twelve dozen buttons of one inch diameter were completely gilt upon both surfaces by five grains of gold. A present, nearly all gilding upon metals is performed by electro-chemical agency. The surface to be gilt is rendered electro-negative, and immersed in a proper solution of gold. Other kinds of gilding are performed by gold leaf, which, if intended for outdoor work, is laid on by the help of *gold size*, i.e. drying oil mixed with calcined red ochre; or, if for picture and looking-glass frames, they are prepared by a size made by boiling parchment clippings to a stiff jelly, and mixed with fine Paris-plaster or yellow ochre. The leaves of books are gilt upon the edges by brushing them over, while in the binder's press, with a composition of four parts of Armenian bole and one of powdered sugar candy mixed up with white of egg; this coating, when nearly dry, is smoothed by the burnisher, then slightly moistened, and the gold leaf applied and burnished. To impress gilt figures on book covers, the leather is dusted over with finely powdered mastic; the iron tool by which the figure is made is then moderately heated and pressed upon a piece of leaf-

GILL

gold, which slightly adheres to it; being then immediately applied to the leather with a certain force, the tool makes an impression, and, softening the mastic, transfers and fixes the gold. In gilding glass and porcelain, powdered gold is blended with gum-water and a little borax, and applied by a camel-hair pencil; the article is then put into an oven or furnace; the gum burns off, and the borax, by vitrifying, cements the gold to the surface, upon which it may afterwards be polished by the burnisher. Sulphide of gold is also used in the potteries for the same purpose.

Gill. A measure of capacity equal to the fourth part of a pint. Miners apply the term to a pint.

Gilliesiaceæ (Gilliesia, one of the genera). A small natural order of Exogens, allied very nearly to *Liliaceæ*. Their principal peculiarity consists in having irregular flowers, surrounded externally by calyx-like bracts. They inhabit Chili, and are of no known use.

Gills (A.-Sax. geahlas). In Physiology, parts of the body are so called in which the blood-vessels are in greater number than is necessary for mere preservation or growth, and are minutely subdivided for the purpose of submitting the blood to the influence of air contained in water.

Gimbals or **Gimbols** (Lat. gemellus, *turn*). A piece of mechanism consisting of two brass hoops or rings which move within one another, each perpendicularly to its plane, about two axes, placed at right angles to each other. A body suspended in this manner, having a free motion in two directions at right angles, will assume the vertical position: hence the apparatus is employed for suspending portable or mountain barometers, sea compasses, &c.

Gimbernati's Ligament. The tendinous expansion of the lower portion of the oblique muscle of the abdomen, by some defined as the third insertion of *Poupart's ligament*.

Gimp. Silk twist, interlaced with brass or other wire.

Gin (Fr. genièvre, *juniper*). Alcohol flavoured by the essential oil of juniper. It was originally made by the Dutch, and is hence distinguished in this country by the name of Hollands. The liquor bearing the above name in this country is of British manufacture, and is frequently flavoured by oil of turpentine, and rendered biting upon the palate by caustic potash. In Holland, the finest gin bears the name of Schiedam, the principal place of its manufacture, where there are many distilleries. [SPIRITS.]

GIN. A species of machinery used in mining operations, whereby a rope, wound round a large horizontal drum, raises, or lowers, the buckets containing the workmen or the produce of the mine. These engines are often worked by a horse traversing a circle.

Ginger (Gr. *zingiberis*). The dried rhizome of *Zingiber officinalis*, a native of the East Indies, and abundantly cultivated in America and the

GIRAFFE

West India islands, whence Europe is chiefly supplied. It is a good stimulant and carminative; and the fresh root preserved makes an agreeable, warm, and not very unwholesome sweetmeat. The acrimony of ginger appears to reside in a resinoid substance, which is soluble in alcohol; hence a spirituous tincture of ginger contains the virtues of the root, and is used under the name *essence of ginger*.

Gingelly. The name of an oil imported from the East Indies for use in lamps. It is expressed from the seeds of *Sesamum indicum*.

Gingham. The name given to a kind of cotton cloth, the manufacture of which was long confined to Lancashire.

Ginglymostoma. In Ichthyology, a genus of small sharks or dog-fish belonging to the family of *Scylliide*, subdivided into two species. They are characterised by a blunt snout, a long barbel from the inner side of the nostrils; the corner fold of the mouth divided by a deep transverse furrow, while the under portion is subdivided by a longitudinal furrow. The teeth, of which there are ten rows, have a simple rhomboidal base, a conical mesial point, and from two to four toothlets on each side. Their liver abounds in a fine oil, which is the only product they yield useful to man.

Ginkgo-tree. The *Salisburia adiantifolia*, a deciduous tree, native of Japan, where it is called Ginkgo, Gin-an, or Its-jo. It forms a conical spiry-topped tree of considerable height, and is remarkable for its leaves, which in their fan-shaped form and straight venation resemble those of the Maidenhair fern, whence it is called also the Maidenhair-tree.

Ginglymus, Ginglymoid (Gr. γγγλυμοειδής, from γγγλυμος, a *joint*). Hinge-like. An anatomical term applied to joints formed for motion in one plane.

Ginseng. A Chinese word applied to the root of the *Panax Schinseng* and *P. quinquefolium*. It has a bitter-sweet flavour, and is considered as a powerful restorative in China, where its consumption is very great. *P. quinquefolium* is found chiefly in the northern parts of Asia, and in America; but the Chinese draw their supplies almost wholly from America. In 1852, there were sent from the United States to China 500,000 lbs. of ginseng, valued at 120,000 dollars. (*Commercial Dict.*)

Gipsy. [GYPSY.]

Giraffe (Arab. kh'ariffa). The tallest quadruped, and the largest and most singular of the Ruminant order. The head of the giraffe resembles that of the camel in the absence of a naked muzzle, and in the shape and organisation of the nostrils, which are oblique and narrow apertures, defended by the hair which grows from their margins, and surrounded by cutaneous muscular fibres, by which the animal can close them at will. This is a beautiful provision for the defence of the air-passages and the irritable membrane lining the olfactory cavities, against the fine particles of sand which the storms of the desert raise in almost suffocating clouds. The large, dark,

and lustrous eyes of the giraffe, which beam with a peculiarly mild but fearless expression, are so placed as to take in a wider range of the horizon than is subject to the vision of any other quadruped. While browsing on his favourite acacia, the giraffe, by means of his laterally projecting orbits, can direct his sight so as to anticipate a threatened attack in the rear from the stealthy lion, or any other foe of the desert. To an open attack he sometimes makes a successful defence by striking out his powerful and well-armed feet; and the lion is said to be frequently repelled and disabled by the wounds which the giraffe has thus inflicted with his hoofs. It is essentially a true Ruminant, having a stomach divided into four compartments, the paunch being simply papillose, without water-bags; and the reticulum with extremely shallow hexagonal cells, as in the reindeer. It is also a horned Ruminant, the horns being two in number, small, straight, and simple, like those of the pricket deer. But in the giraffe the bony base of each horn is articulated by a broad rough epiphyseal basis to the cranium; it is covered by a vascular periosteum and a hairy integument, which is not deciduous. These horns, or rather antlers, terminate in a truncate extremity capped with a callous plate, and fringed with long and strong black hairs: they are present in both sexes, as in the reindeer, but are larger in the male, and are by no means the insignificant weapons that they have been supposed to be. The median protuberance is a simple thickening of the contiguous parts of the frontal and nasal bones. In the form of the mouth the giraffe differs from every other Ruminant. The upper lip is not bifid, as in the camel; and though it is prolonged and covered with hair, as in the elk, it differs in its elegant and tapering form.

The giraffe has a long neck, and has not spurious hoofs, and so far it resembles the camel; but the cervical vertebrae in the camel tribe present a peculiarity of structure, combined with their length, in which the giraffe does not participate. The camels have many other peculiarities of internal organisation, to some of which we find resemblances in certain ordinary Ruminants, but not in the giraffe. Its place in the Ruminant series is between the deer and the antelope. These extensive families are respectively distinguished, not only by the nature of their horns, but by a well-marked anatomical character: the gall-bladder is present in the antelopes, and not in the deer. In three giraffes lately dissected in this country, a gall-bladder was present in one, and not in the other two. In that in which it was discovered it presented an abnormal structure, being bifid at the fundus, and divided into two compartments. We may infer, therefore, that in this part of their organisation, as in the structure of their horns, the giraffes are more nearly akin to the deer tribe than to the antelopes. Yet it must not be forgotten that while we search in vain among the *Cervidae* for an equine mane

and tufted tail, such as ornament the giraffe, we find both these peculiarities combined in the gnu among the antelopes. A giraffe more than two-thirds grown will eat daily in confinement eighteen pounds of clover hay, and eighteen pounds of a mixed vegetable diet, consisting of carrots, mangold wurtzel, barley, split beans, and onions; and will drink four gallons of water. They copulate in March. The female has four inguinal adders; she brings forth one fawn at a birth; and the period of gestation is fifteen months. The new-born giraffe measures six feet from the fore-hoofs to the top of the head. In a few hours it is able to follow the dam. It resembles the mature animal in the markings of the hide. The first giraffe known to have been produced in captivity was brought forth in June 1839, at the gardens of the Zoological Society of London.

Girasol (Ital. girasole). A milk-white or bluish Opal, which, when turned to the light, reflects a reddish colour; hence its name, from the Latin *gyrus*, a circle, and *sol*, the sun.

GIRASOL. The Italians gave this name to the artichoke as being a kind of sunflower; hence the English corruption of Jerusalem artichokes, followed by the invention of Palestine soup.

Girder. In Architecture, a principal beam in a floor, for supporting the binding or other joists, whereby their bearing, or length, is lessened. Girders are of several sorts, such as cast iron, wrought iron, boxed, framed, and trussed; they are now used quite as much for the support of the main walls of a building, or for the support of the roadway of a bridge, as for floors.

Girdle (A.-Sax. *girdan*, to encircle, Goth. *gairda*). A belt or band, of leather or some other substance, used in girding up the loins. The girdle (Gr. *ζώνη*, Lat. *cingulum*) was in use among the Hebrews, Greeks, and Romans, for various purposes, and chiefly while at work or on a journey. They were also worn by young women at all times before marriage. Hence *Zonam solvere virginem* was a well-known phrase appropriated to the marriage ceremony. To Aphrodite or Venus was attributed by the poets the possession of a particular kind of girdle, called *cestus*, which was said to have the power of inspiring love.

It was formerly the custom in England for bankrupts or other insolvent persons to put off and surrender their girdles in open courts.

Gironde, the. In French History, a celebrated political party during the Revolution, the members of which were termed Girondists or Girondins. The name was derived from that of the department *La Gironde* (in which Bordeaux is situated), which sent to the legislative assembly of 1791, among its representatives, three men of eloquence and talent (Guadet, Gensonné, Vergniaud), who were among the chief leaders of the party. Its principles were republican. During the continuance of that assembly the

Girondists formed a powerful, but not always consistent party. Out of these Louis XVI. chose his republican ministers in the beginning of 1792. But after the massacres of September in that year the party in general withdrew from all connection with the Jacobins, and approximated towards the Constitutionalists. In the Convention the Girondists at first commanded a majority, but on the king's trial they were much divided; and, being pressed by the violence of the sections of Paris, they were at length expelled the assembly: thirty-four of them were outlawed, and finally twenty-two of their leaders guillotined (Oct. 7 and Oct. 31, 1793), while a few escaped, and others put an end to themselves. Perhaps the most celebrated member of the Gironde party was a lady, Madame Roland, the wife of the minister of that name, who was executed when the party fell, and whose principal writing—the *Appel au Peuple*—bears all the stamp of that high republican enthusiasm which characterised them. Various apologies and eulogies of the party have appeared. Its members were not without high qualities; but its counterpart will be found in all revolutions, in that body of men of high theoretical views of social reform and little practical knowledge, who, being commonly lifted into power by supporters more energetic but less high-principled than themselves, are sure to be thrust down in a short time by their own former adherents. (See particularly the histories of Thiers and Louis Blanc for general views on the subject; for details, the *Histoire Parlementaire* of Messrs. Buchez and Roux; and the famous, but somewhat romantic, *History of the Girondins* by Lamartine, which produced so great an effect on the public mind in the Revolution of 1848.)

Girouette (Fr. *a weathercock*). Public characters who turn with every political breeze. The French published a *Dictionnaire des Girouettes*, containing the names of the most celebrated revolutionary characters, with a number of weathercocks against each, corresponding to the number of his political changes.

Girt Line. A rope to lift the rigging and riggers up to the masthead on first rigging the ship.

Gismondine. A native hydrated silicate of alumina, lime and potash, first noticed at Capo di Bove, near Rome, by Gismondi, after whom it was named.

Githagin. A soap-like matter found in the corn cockle (*Agrostemma Githago*).

Gizzard (fr. *gésier*). The proper stomach of birds; its texture differs remarkably in granivorous and carnivorous birds, being thick in the one and thin in the other.

Glabrous (Lat. *glaber*, *smooth*). A term applied in Mammalogy to those parts of the surface of a quadruped which are naturally devoid of hair; and in Botany and Entomology, when a surface is smooth, and devoid of hair or pubescence.

Glacial Drift. The surface of much of

Northern Europe and North America is strewed at intervals with remarkable accumulations of large and small blocks of stone (some angular, some rounded), mixed with sand and clay, all heaped irregularly on the other rocks, but sometimes including stratified deposits. The solid rocks are often greatly scratched, and not unfrequently polished, under these deposits, as if they had been dragged or drifted along for some distance. Sometimes the deposits are in definite lines; sometimes the heaps have definite forms. To account for these curious heaps, of which GRAVEL is one of the component parts, it is necessary to study the action of ice, whether moving over a surface of land loaded with stones and rubbish, or broken away from the land and drifted along by marine currents. The former condition introduces the subject of GLACIERS, the latter of ICEBERGS [see those articles].

The action of a glacier in producing drift is peculiar, but easily understood. Large quantities of stones, sand, mud, and other material, derived from the hourly disintegration of rocks on high exposed mountain sides, fall into the valleys, and are there caught up by the snow, and at length, by the constant change going on in the newly forming ice, are arranged in long lines distributed through the mass. Those at the sides and bottom, pressed on by the whole weight of the moving ice, rub, scratch, and cut away the ground below, thus adding to the material moved. The whole at length reaches the place where the ice is melting, and is there accumulated or carried away by the stream. The path of the glacier is inevitably marked by these accumulations; and if at any time the glacier should melt away entirely, the rubbish would be left as drift. Such drift cannot have been moved far, and may generally be traced to its origin.

Where, however, in cold climates the glacier reaches to the sea coast, and then advances into the water till it becomes broken off, the accumulation of drift may be so distributed among the mass, that when separated, the portion of a glacier, now an iceberg, may contain an enormous load of broken rock and mud. Entering the sea, and drifted by marine currents, the huge mass thus loaded will either melt by degrees as it enters warmer latitudes, or will be caught by some shoal and stopped on its way. In the first case a multitude of blocks and stones will be strewn with a certain degree of regularity along a line of sea bottom, and will probably be drifted into hollows, or large heaps of all kinds without order or arrangement. Otherwise it will be left on the shoals and higher ledges of rock on which the bergs have stranded. Thus have been produced the various phenomena of glacial drifts. They are often greatly complicated in nature, by subsequent elevation and denudation, and the partial covering by other newer accumulations. [GLACIERS and GLACIAL PHENOMENA.]

Glacial Phenomena. Phenomena indicating glacial action. They are very numerous

GLACIERES

and varied, and include many appearances that would not at first be thought referable to such action as that of ice. Gravel deposits generally, gravel hills of a certain form having one side steep and the other an easy slope always in the same direction, isolated boulders, surfaces of rock smoothed, rounded, scratched, or otherwise acted on by the friction of heavy bodies—these are the ordinary phenomena. Long trains of gravel and sand, indentations scooped out of rocks like ledges, ancient beaches partly covered by gravel, partly by shells belonging to arctic regions, certain bones and other remains of quadrupeds—all these are also glacial phenomena. They are all indications of a time not very distant, geologically speaking; when the greater part of the temperate region of the northern hemisphere was covered with water (the land extending towards the pole), and large quantities of glacial ice stretched away into the open valleys and floods of the high mountain chains, breaking off into icebergs which float far down and not unfrequently strand on shoals and on some of the islands. This period is so distinctly marked by the phenomena in question, that no doubt can exist as to its continuance for a long period. [GLACIERS and GLACIAL DRIFT.]

Glacières (Fr.). In Geology, this name is given to caves full of ice, which are found chiefly in the Alpine mountains in spots quite unconnected with any glacial system. These caves are interesting chiefly as occurring in localities where the mean temperature of the surface of the earth is much above the freezing point, and at depths below the surface varying from 50 to 200 feet, thus furnishing exceptions to the rule of the increase of temperature from the surface towards the centre of the earth. One of these caves, at Monthezy in the Val de Travers, exhibits the phenomenon of alternating currents of air, moving in each direction for about twenty-two seconds, with an interval of four seconds of inaction. Among such ice-caves are the glacières La Genollière, S. Georges, Prê de S. Livres, in the Jura, and of La Baume near Besançon. Similar caves are found in Hungary, and at Yeermalik in Koondooz: and to these may be added the caves of the Jurtshellir in Iceland, and the gypsum cave of Illetzkaya-Zastchitsa, in the steppes of the Khirghis, south of Orenburg. (Browne's *Ice-caves of France and Switzerland*.)

Glaciers (Fr.). The name given to the immense masses of ice which accumulate on the peaks and slopes, and in the upper valleys, of lofty mountains. The phenomena of glaciers form one of the most interesting subjects of scientific investigation, whether we regard their formation, structure, or appearance. In all parts of the globe glaciers have the same general characteristics; but though the glaciers of other countries have often been described by geographers and naturalists, it is chiefly in respect to those of Switzerland that we possess detailed information. In that country, as indeed in every other, those parts of the mountains that

GLACIERS

rise above the line of congelation are covered with perpetual snow, which being partially thawed during the summer months, is on the approach of cold converted into ice, thus constituting what is called a *glacier*. The ice so formed descends along the slopes of the mountains into the valleys, by which their ridges are furrowed, and there it accumulates into vast beds or fields, presenting, where the descent is gradual, a very level surface with few crevices, but where there is a rapid or rugged declivity being rent with numerous chasms and covered with elevations rising from 100 to 200 feet. These chasms are frequently many feet wide and more than 100 feet deep. Their formation never takes place in winter, but is frequent during summer; and the daily, and almost hourly, changes to which these chasms are subject, are the chief causes of danger to travellers in ascending glaciers. (*Geographical Dictionary*, art. 'Alps.') Though the snow-line on the Alps is found at an elevation of about 8,000 feet above the level of the sea, some of the glaciers descend so far downward that their lower extremity is not more than 3,500 feet above it. This is particularly the case in the valley of Chamouni, where the singular spectacle is presented of huge pyramids of ice of a thousand fantastic shapes in juxtaposition with the most luxuriant pastures, or towering in majestic grandeur in the midst of verdant for

the descent of the glaciers is twofold: viz. one of a slow and gradual character, by which a progressive movement of about twenty-five feet annually is effected; the other of a rapid and impetuous kind, in which a portion of the ice having been severed from the main body glides down the mountain's side, accumulating as it goes, and precipitating into the valleys beneath immense stones, fragments of rock, and other substances to which it had adhered. When the débris which the glaciers accumulate in their descent has been deposited in the valleys, it constitutes what in Savoy is termed their *moraine* or border, an essential feature in the Alpine glaciers. These borders present every variety of aspect; but their most usual appearance is that of unfathomable bogs or morasses wholly destitute of vegetation, and in many instances fraught with extreme peril to the traveller. They are generally arranged in long ridges or mounds from thirty to forty feet high; and being often two, three, or even four in number, resemble so many lines of intrenchment.

The Alpine glaciers occupy a superficial extent of 1,184 square miles. From Mont Blanc to the borders of the Tyrol there are reckoned about 400, of which the greater number vary from 10 to 15 miles long, and from 1 to 2½ broad; their mean vertical thickness ranges from 100 to 600 feet. Besides the grand and picturesque appearance which they present externally, their lower extremities are sometimes excavated by the melting of the ice into the form of immense grottoes, adorned with the finest stalactitic crystallisations, whose bril-

GLACIERS

liant azure tints are reflected on the streams and torrents which generally issue from these caverns, forming altogether a picture so beautiful as to defy the most faithful pencil to portray it adequately. The glacier ice does not resemble the ice found in ponds and rivers. Not being formed in layers, but consisting of small grains or crystals of congealed snow, it has neither the compactness, the solidity, nor the transparency of river ice; and though every single crystal seems perfectly white, the whole mass is of a blue colour, passing through every variety of shade, from the most feeble sky-blue to that of the lapis lazuli. From the large accessions of snow and ice which the glaciers receive, especially in winter, it might reasonably be conjectured that they must be gradually increasing in size, and would consequently in the course of time break through their usual limits and overwhelm the cultivated lands of the surrounding country. This, however, is by no means the case. It no doubt often happens that on some occasions the glaciers are observed to descend lower than usual; but, when this takes place, the warm atmosphere of the lower valleys into which they have advanced, and of which the temperature rises in proportion to their depression, operates with such powerful effect in reducing their bulk, that they are invariably found to recede proportionably. Thus nature has established a compensating process, by which an effectual though simple check is administered to the encroachment of the glaciers upon the cultivated lands of the Alpine valleys.

The results of glaciers will be best understood by a reference to the special articles on GLACIAL DRIFT and GLACIAL PHENOMENA. They have been produced on the surface of the land in many parts of Europe now altogether free from ice except during a short season in winter. This is so clear as to render it certain that there was a time, geologically not very remote, when much of the land now cultivated was covered with ice proceeding from elevations so low as to be utterly inadequate in the present climate of the district to produce a glacier of importance. It follows that they afford valuable points of geological evidence of change of climate when carefully studied with this view.

The structure and motion of glaciers have been elaborately investigated by Rendu, Agassiz, Forbes, and Tyndall. The last-named physicist, who has most recently studied the subject with much success, gives the following summary of glacier phenomena:—

1. Glaciers are derived from mountain snow, which has been consolidated to ice by pressure.
2. That pressure is competent to convert snow into ice, has been proved by experiment.
3. The power of yielding to pressure diminishes as the mass becomes more compact; but it does not cease even when the substance has attained the compactness which would enable it to be called ice.
4. When a sufficient depth of such a substance collects upon the earth's surface, the

lower portions are squeezed out by the pressure of the superincumbent mass. If it rests upon a slope, it will yield principally in the direction of the slope, and move downwards.

5. In addition to this, the whole mass slides bodily along its inclined bed, and leaves the traces of its sliding on the rocks over which it passes, grinding off their asperities, and marking them with grooves and scratches in the direction of the motion.

6. In this way the deposit of consolidated and unconsolidated snow, which covers the higher portions of lofty mountains, moves slowly down into an adjacent valley, through which it descends as a true glacier, partly by sliding and partly by the yielding of the mass itself.

7. Several valleys thus filled may unite in a single valley the tributary glaciers, welding themselves together, to form a trunk glacier.

8. Both the main valley and its tributaries are often sinuous, and the tributaries must change their direction to form the trunk; the width of the valley often varies. The glacier is forced through narrow gorges, widening after it has passed them; the centre of the glacier moves more quickly than the sides, and the surface more quickly than the bottom; the point of swiftest motion follows the same law as that observed in the flow of rivers, shifting from one side of the centre to the other as the flexure of the valley changes.

9. These various effects may be reproduced by experiments on small masses of ice. The substance may moreover be moulded into vases and statuettes. Straight bars of it may be bent into rings, or even coiled into knots.

10. Ice capable of being thus moulded is practically incapable of being stretched. The condition essential to success, is that the particles of the ice operated on shall be kept in close contact, so that when old attachments have been severed new ones may be established.

11. The nearer the ice is to its melting point in temperature, the more easily are the above results obtained; when ice is many degrees below its freezing point, it is crushed by pressure to white powder, and is not capable of being moulded as above.

12. Two pieces of ice at 32° Fahr., with moist surfaces, when placed in contact, freeze together to a rigid mass; this is called *regelation*.

13. When the attachments of pressed ice are broken, the continuity of the mass is restored by the regelation of the new contiguous surfaces. Regelation also enables two tributary glaciers to weld themselves to form a continuous trunk; thus also the crevasses are mended, and the dislocations of the glacier, consequent on descending cascades, are repaired. This healing of ruptures extends to the smallest particles of the mass, and it enables us to account for the continued compactness of the ice during the descent of the glacier.

14. The quality of *viscosity* is practically absent in glacier ice. Where pressure comes

GLACIERS

into play, the phenomena are suggestive of viscosity; but where tension comes into play, the analogy with a viscous body breaks down. When subjected to strain, the glacier does not yield by stretching, but by breaking; this is the origin of the crevasses.

'15. The crevasses are produced by the mechanical strains to which the glacier is subjected. They are divided into marginal, transverse, and longitudinal crevasses; the first produced by the oblique strain consequent on the quicker motion of the centre; the second by the passage of the glacier over the summit of an incline; the third by pressure from behind and resistance in front, which causes the mass to split at right angles to the pressure.

'16. The moulins are formed by deep cracks intersecting glacier rivulets. The water, in descending such cracks, scoops out for itself a shaft, sometimes many feet wide, and some hundreds of feet deep, into which the cataract plunges with a sound like thunder. The supply of water is periodically cut off from the moulins by fresh cracks, in which new moulins are formed.

'17. The lateral moraines are formed from the débris which loads the glacier along its edges; the medial moraines are formed on a trunk glacier, by the union of the lateral moraines of its tributaries; the terminal moraines are formed from the débris carried by the glacier to its terminus, and there deposited. The number of medial moraines on a trunk-glacier is always one less than the number of tributaries.

'18. When ordinary lake-ice is intersected by a strong sunbeam, it liquefies, so as to form flower-shaped figures within the mass; each flower consists of six petals, with a vacuous space at the centre; the flowers are always formed parallel to the planes of freezing, and depend on the crystallisation of the substance.

'19. Innumerable liquid discs, with vacuous spots, are also formed by the solar beams in glacier-ice. These empty spaces have been hitherto mistaken for air-bubbles, the flat form of the discs being erroneously regarded as the result of pressure.

'20. These discs are indicators of the intimate constitution of glacier-ice, and they teach us that it is composed of an aggregate of parts, with surfaces of crystallisation in all possible planes.

'21. There are also innumerable small cells in glacier-ice holding air and water; such cells also occur in lake-ice; here they are due to the melting of the ice in contact with the bubble of air. Experiments are needed on glacier-ice in reference to this point.

'22. At a free surface within or without, ice melts with more ease than in the centre of a compact mass. The motion which we call *heat* is less controlled at a free surface, and it liberates the molecules from the solid condition sooner than when the atoms are surrounded on all sides by other atoms which impede the molecular motion. Regelation is the comple-

GLADIATORS

mentary effect to the above; for here the superficial portions of a mass of ice are made virtually central by the contact of a second mass.

'23. The dirt-bands have their origin in the ice-cascades. The glacier, in passing the brow, is transversely fractured; ridges are formed with hollows between them; these transverse hollows are the principal receptacles of the fine débris scattered over the glacier; and after the ridges have been melted away, the dirt remains in successive stripes upon the glacier.

'24. The ice of many glaciers is laminated, and when weathered may be cloven into thin plates. In the sound ice, the lamination manifests itself in blue stripes, drawn through the general whitish mass of the glacier; these blue veins representing portions of ice from which the air-bubbles have been more completely expelled. This is the veined structure of the ice. It is divided into marginal, transverse, and longitudinal structure; which may be regarded as complementary to marginal, longitudinal, and transverse crevasses. The latter are produced by tension, the former by pressure, which acts in two different ways: firstly, the pressure acts upon the ice as it has acted upon rocks which exhibit the lamination technically called *cleavage*; secondly, it produces partial liquefaction of the ice. The liquid spaces thus formed help the escape of the air from the glacier; and the water produced, being refrozen when the pressure is relieved, helps to form the blue veins.

Glacies Mariæ (Lat.) or **Glace de Marie** (Fr.). Terms applied to largely foliated Mica.

Glacis (Fr.). In Fortification, a bank of earth, which forms the parapet of the counterscarp, and conceals the scarp wall. It slopes gently off to the level country.

Gladiators (Lat. *gladiatores*, from *gladius*, a sword). In Roman Antiquities, sword players, who were originally employed to fight at the funerals of illustrious Romans, in order to appease their manes by the effusion of blood. They were subsequently introduced into the public amphitheatres, and became one of the most favourite spectacles of the Roman people. The gladiators were either captives or condemned criminals, or else people of the lowest rank, who served for hire, the profession being considered one of the greatest infamy. In spite of this, however, under some of the emperors, persons of the first families, who had enjoyed the highest honours of the state, entered the arena, either at the command of the despot, or in order to gratify him; and even females of patrician blood, in some instances, followed their example. Gladiators did not merely use the sword, as their name strictly implies, but were armed in various ways. Thus, the *Laqueatores* used a noose (*laqueus*) to catch their opponents: and the *Retiarii* carried a three-pointed lance with a net (*rete*) wherewith to entangle their adversaries. The gladiators were, in general, desperate and ruffian characters; and considerable bodies of them were sometimes kept in the pay of wealthy and tur-

GLADIOLUS

bulent citizens, or hired as bullies. Perhaps the best exposition of the opinion of the more philosophical Romans on the subject is thus given by Cicero: 'Crudele gladiatorum spectaculum et inhumanum nonnullis videri solet: et haud scio an non ita sit, ut nunc fit: cum vero fontes depugnabant, auribus fortasse multa, oculis quidem nulla poterat esse fortior contra dolorem et mortem disciplina.' (*Thuc. Quæst. 2.*) It is commonly but inaccurately said, that the shows of gladiators were put a stop to by the Christian emperors. They certainly had not ceased in A.D. 404, and probably not before the conquest of Italy by the Goths. (Beugnot, *Destruction du Paganisme en Occident*, book ix. ch. ii.)

Gladiolus (Lat. dim. of *gladius*, a sword). The beautiful plants which bear this name in modern gardens are the results of intercrossing of some two or three South African species, especially *G. natalensis*, *floribundus*, and *cardinalis*.

Gladius (Lat.). The name of the internal horny plate of the calamaries, which was called by the Greeks *ἐλπίς*, or the sword.

Glaïr. The white of an egg; or any viscous transparent substance resembling it.

Glaïrin. *Baregin*. A nitrogenous matter existing in some sulphurous springs.

Glaïce Coal. [ANTHRACITE.]

Gland (Fr. *glande*, from Lat. *glans*). In Anatomy, this term is applied to those organs of the body in which *secretion* is carried on, and which appear to consist of a congeries of blood-vessels, nerves, and absorbents: they are frequently distinguished according to their secretion, into mucous, sebaceous, lymphatic, and lachrymal; or, according to their form and texture, into simple, compound, conglobate, and conglomerate.

GLAND. The cupped collar, lined with brass, which encircles the piston or air-pump rod of a steam engine where it passes through the cylinder cover; it is introduced for the purpose of holding oil or tallow for the lubrication of the working parts, and for compressing the packing of the stuffing box upon which it is screwed down. The term is generally applied in the sense of a joint holding lubricating fluid, with tight packing.

Glands or Glandules. In Botany, wart-like swellings of various forms, found on the surface of plants, or at the base or apex of their hairs. Lenticular glands are brown oval spots found upon the bark of many plants, especially willows, indicating the points from which roots will appear if the branch be placed in circumstances favourable to their production. They are, in fact, nothing but protuberances formed by the pressure upon the epidermis of subjacent roots attempting to pierce through it.

Glands, Buccal (Lat. *bucca*, the cheek). These glands are divided into the *parotid*, *sublingual*, and *maxillary*. They secrete the saliva or lubricating fluid of the mouth.

Glanders. A disease so called from its inflaming the glandular system. It attacks the

GLASS

horse, the mule, and the ass. It appears to be contagious, and from recent observations has been shown to assume two forms: the being the true glanders, a local disease especially attacking the nasal mucous membrane; and the other a more general affection, known under the name of *farcy*, and attacking the lymphatic or absorbent system.

Glanders may extend to the bronchial membrane, and assume several different forms. Thus, there may be merely a mild discharge, lasting for many weeks, and a cure may then be brought about; or, on the contrary, the secretion from the nose may become green, black, or sanguinolent, and ulceration of the nasal bones may ensue, with great destruction of soft parts.

Farcy has been differently designated, as different parts of the lymphatic system become involved. Thus we hear of *button* and of *bud* *farcy*, terms applied to the disease when it affects the lymphatic glands, and forms bosses on the extremities and other parts of the animal; and again the term *pape* *farcy* is used when the lymphatic vessel is diseased.

Acute glanders is sometimes observed in the human subject, owing to the foul secretion from the brute animal becoming absorbed. Persons so inoculated show marked adynamic symptoms, great discharge from the nose, while a pustular eruption breaks out upon the skin. The lungs soon become involved in inflammation, and death speedily ensues.

Glaïss (Lat.). In Botany, an inferior indehiscent fruit, one-celled by abortion, and seated in a cupule or cup; as represented in the acorn.

Glaïss (Dan. *glas*). The manufacture of glass is one of the highest interest; and considering the comparative worthlessness of the materials of which it is made, and the purposes, useful, ornamental, and which it subseves, may be regarded as the most important of inventions. The of its discovery is involved in great obscurity; but if we believe Pliny, we are indebted for it to the Phenicians—his tale being that a merchant-ship laden with natron (impure soda) having been driven upon the coast near the mouth of the river Belus in tempestuous weather, the crew were compelled to cook their victuals ashore; and having placed lumps of the natron upon the sand as supports to the kettles, found, to their surprise, masses of transparent stone among the cinders. But, be this as it may, the Egyptians were certainly acquainted with the art of glass-making; for in some nomes [Nomes] glass beads have been found coloured with a metallic oxide, and pieces of glass have been discovered in the ruins of Thebes. (M. Boudet, *Desc. de l'Égypte*, vol. ix.; *Aul. Mémoires*.) In the time of Strabo and Pliny, the inhabitants of Sidon were famed for the production of beautiful glass, which they cut, engraved, and stained of the richest colours, in imitation of precious stones, and exported to all parts of the then civilised world. For a long time

Venice is said to have excelled all the countries of Europe in this manufacture; of which, indeed, it enjoyed a monopoly till about the middle of the seventeenth century. The period at which the manufacture of glass was introduced into England is not precisely known; but there can be no doubt that till near the close of the seventeenth century, this country was obliged to have recourse to foreigners for the supply of the common article of drinking glasses. In 1673, the duke of Buckingham materially improved the fabrication of British plate glass by bringing over several Venetian artisans to the works at Lambeth, which were under his patronage; and the manufacture was still further improved by the arrival of the French refugees after the revocation of the edict of Nantes. The above works, however, were soon abandoned; and it was exactly one century (1773) later that the first large establishment for the production of plate-glass was formed, under the title of 'The Governor and Company of British Cast Plate-Glass Manufacturers.' This company was incorporated by Act of Parliament, and soon after erected works on an extensive scale at Ravenhead near St. Helens, in Lancashire, which have continued in constant operation down to the present time. Since that period immense improvements have been made in the manufacture of every species of glass throughout all the countries of Europe.

Crown glass and flint glass have reached the highest perfection in England; in plate glass Great Britain is more than rivalled by France; while in glass for philosophical apparatuses, Germany and France are greatly in advance of this country. But although the French plate is superior to ours in quality, it is considerably higher in price. In fact, the great reduction that has been effected in the cost of this glass has, of late years, led to its largely extended use for window glass in Great Britain.

The application of glass to the glazing of windows is of comparatively recent introduction into dwelling-houses, though it was general in churches and other public buildings as early as the third or fourth century. In London, this manufacture was first begun in 1557; but that the use of window glass was by no means universal even twenty years later, is evident from the fact that at Alnwick Castle, the residence of the duke of Northumberland, the glass case-ments used at that period to be taken down in the absence of the family, to preserve them from accident. (*Domestic Architecture in England from Richard II. to Henry VIII.* part i. p. 121.) In Scotland, even in the early part of the last century, glass was seldom seen in the windows of country houses; and a few years previously, even in the royal palaces and the town houses of the nobility, the windows of the upper storeys alone were furnished with it. Since that period, however, a great change has been effected; for now even the windows of the meanest cottage are, almost without excep-

tion, supplied with glass, which ought rather to be considered as a necessary of life, than as the most elegant and useful of conveniences.

Composition and Manufacture of Glass.—Glass is essentially a compound of silica with potash or soda; other silicates, more especially those of lead and lime, being occasionally added. Transparency and insolubility in water are among the essential qualities of glass; but it should also resist the action of other solvents, such as acids and alkalies, and for many purposes it should not fuse or even soften at a red heat. The insolubility of glass depends much upon its aggregation, for if reduced to fine powder it reddens turmeric paper when moistened, and a portion of its alkali is frequently abstracted by long exposure to air and water; so also the glasses containing oxide of lead are readily discoloured by sulphuretted hydrogen, when in powder and diffused in water, although they long resist its action when in their ordinary state. The more fusible glasses, containing excess of alkali, of oxide of lead, or of lime, are also apt to be acted on by acids and alkalies, and are unfit for the retention of such solutions; and all glass is more or less disintegrated by the action of water at very high temperatures.

As the varieties of glass are mixtures rather than definite compounds of their component silicates, they scarcely admit of being represented by formulae, though in some cases the proportion which the oxygen of the bases bears to that contained in the silica may be usefully stated. The large proportion of oxide of lead in *flint glass* gives it a high refractive power and brilliancy when cut, but renders it soft, easily fusible, and liable to be acted on by many chemical agents. In *plate glass* the predominance of silicate of soda gives a more liquid combination than potash, and enables it to be poured out of the crucible in which it is melted, upon a cast-iron table, and rolled into sheets, which, after careful annealing, are ground to a level surface with emery, and ultimately polished with colcothar. Large quantities of the waste and broken glass of former operations are frequently melted up (under the name of *cullit*) with the materials in the crucible. The remarkably tenacious viscosity of glass, when in a fit state for the operations of the glass-house, and the facility with which it is shaped, by blowing, moulding, and other manipulations, into its infinitely various forms, can only be understood by personal inspection.

The following table will give an approximate notion of the relative proportions of the components of several kinds of glass in common use:

	Plate		Crown		Flint		Bottle		Tube		Optical	
Silica	78	63	62	59	73	43						
Potash	2	22	14	2	12	12						
Soda	13	10	3	..						
Lime	5	13	..	20	11	..						
Alumina	2	3	1	2	1	1						
Oxide of Lead	33	44						
Oxide of Iron	7						
	100	100	100	100	100	100						

A glass composed of borate and silicate of lead

GLASS

has been used by Faraday for some optical purposes, and the borosilicate of zinc has been similarly applied by Maetz and Clemandot.

All glass requires to be carefully *annealed*—that is, suffered to cool very slowly—otherwise it becomes liable to fly to pieces upon the slightest touch of any substance hard enough to scratch its surface. Small unannealed flasks, blown from samples taken from the pot, for the purpose of ascertaining the quality of the glass, and known in the glass-house under the name of *proofs*, well show this. When a fragment of flint is dropped into them they immediately crack; and if melted bottle glass be dropped into water, so as to form what are called *Rupert's drops*, the instant that their thin end is broken off they crumble into powder with a kind of explosion. This probably arises from the unequal tension of the layers of glass in consequence of the sudden cooling of the exterior, whilst the interior remains dilated, or even red-hot. When large masses of glass are slowly cooled, crystallised nodules are sometimes formed, more or less opaque, and embedded in the transparent glass. These appear to arise from the crystallisation of definite silicates.

When glass, embedded in sand, is heated up to a point a little below that of fusion, and allowed to cool slowly, it is converted into *Reaumur's porcelain*: it has become hard, white, opaque, and somewhat less fusible—changes which have been referred to the formation of certain definite crystallisable silicates, more especially those of lime and alumina. These phenomena of *devitrification* are best shown with common green bottle glass.

A peculiar glass is used for the manufacture of artificial gems, called *strass* or *paste*, containing a large quantity of oxide of lead, and frequently borate of lead. It is easily fusible, highly refractive, and very soft. [GEMS, ARTIFICIAL.]

The art of *colouring glass* depends upon its power of dissolving certain metallic oxides. The principal metals thus employed are: 1. *Gold*: it imparts various shades of red or pink, inclining to purple; 2. *Silver*: oxide, chloride, or phosphate of silver give a yellow colour; 3. *Iron*: The oxides of iron produce blue, green, yellow, or brown, dependent upon the state of oxidation and quantity. The protoxide gives various shades of green; the peroxide of brownish yellow; 4. *Manganese*: The protoxide leaves the glass colourless, but the peroxide gives it various tints of violet, and, if added in excess, renders it black. This oxide was formerly called *glass soap*, from its property of destroying the green tint communicated by protoxide of iron, derived from the use of impure materials; this it effects by converting the protoxide of iron into peroxide, which, in small proportions, does not materially affect the colour of the glass; whilst the peroxide of manganese, losing oxygen, becomes protoxide, and in this state is also not injurious. A little nitre is sometimes used for the same purpose;

GLASS PAINTING

5. *Copper*: the protoxide gives a rich green, and the dioxide a ruby red. The glittering appearance of *aventurin* glass is due to the dissemination of minute crystals of metallic copper, produced by the fusion of a mixture of iron and copper scales in the glass; 6. *Cobalt*, in the state of oxide, gives beautiful blues of all shades—in large quantity black; 7. *Chromium* produces greens and red, depending upon its state of oxidation; 8. *Uranium* is the source of the peculiar opalescent yellowish-green glass; 9. *Tin*, in the state of binoxide, gives the varieties of opalescent glass, terminating in opaque white enamel, in which there is also a little oxide of lead. An alloy of 1 part of tin and 2 of lead is calcined for the production of the oxides, and these are mixed with powdered glass. When surfaces are to be enamelled, this mixture is applied with a brush, and then fused by exposure to heat in a muffle. The colours used in enamel painting are derived from the metals above enumerated. A species of enamel is sometimes applied to iron saucers and other vessels; it is a vitrifiable mixture of powdered flint with carbonate of soda, borax, and Cornish clay, with a little oxide of tin; this is brushed over the surface, then carefully dried, and heated in a muffle to bright redness; 10. *Arsenic*: Arsenious acid is much employed for giving an *opal* tint to glass. This glass is translucent, of a pale bluish-white colour, with a reddish hue when viewed in certain lights. On powdering this glass, and applying the usual tests for arsenic, the presence of this substance may be readily detected. Arsenious acid, in small quantity, by peroxidising iron, which usually gives a green tint, tends to render glass colourless.

Glass Gail. The saline scum which rises to the surface of fused glass in the glass pots; it is also called *sandiver*.

Glass Painting. The art of painting upon glass, with vitrifiable colours, in contradistinction to the use of coloured glass, in which the colour forms part of the composition of the glass itself. Remains of painted glass have been discovered in the ruins of the Assyrian, Egyptian, Greek, Etruscan, and Roman cities; but the introduction of painted glass, for windows, does not seem to have been practised generally till the twelfth century of the Christian era. From that period to the end of the sixteenth century, the art appears to have been cultivated with great splendour; it then began to decay, and it is only within thirty years that it has again recovered its hold upon public attention.

The ancient glass painting was generally executed in pieces of that material cut out to the shape of the colour which the artist wished to introduce, so that the windows resembled tables of mosaic work, in which there was no attempt at shading or modification of the tone. The colours used to form the ground of the pictures are the red, blue, and yellow; the two compound colours, the green and violet; the plain glass, and the slightly yellow, which being mixed with red yielded carnation; they

GLASS PAINTING

were sometimes shaded with brown, which seems to have been the only vitrifiable colour then known. Latterly, the artists have aimed at producing the effect of oil painting upon glass, and they have modified the system of employing the detached portions; they have shaded the whole of their compositions, and have thus materially diminished the effect of them. The old glass was always set in lead, which had a material influence upon the design adopted by the artists, because the setting defined the outline and limited the colours in a very distinct manner; this is not effected in the large paintings now executed, in which the artist is obliged to trust to the shadows, and to the variations of tint, for the definition of their outline; and the modern glass-painting lacks the sharpness and brilliant colour of the old precisely on account of this modification in detail. One great difficulty, however, attends every painting on glass, arising from the fact that the light being transmitted through the picture instead of being, as in oil painting, reflected from the surface, the artist is obliged to resort to a different set of principles to produce the effect. It requires, in fact, a distinct series of experiments before the method of obtaining the desired lights and shades with any peculiar colour can be ascertained; the depth of tone and the thickness of the glass must also be settled in this manner. We must not, however, forget, whilst discussing this branch of the subject, that the red glass used in the ancient windows is always double, or consists of white glass lined or coated with red. The mode of effecting this was by dipping the blow-tube into white glass in fusion, and subsequently into red, which was then blown into cylinders, and flattened.

There are two systems of painting on glass now used; the one consists of applying the colours with a water vehicle, somewhat in the same manner as water colours; the other consists in applying them with an essential oil vehicle, which does not evaporate so easily, and requires a higher temperature to fix the colours. Nearly all the English works have of late years been produced by the water-colour process, and they seem to have faded, at least when compared with the foreign works. One of the most successful specimens of modern glass painting is the decoration of the church of St. Vincent de Paul, in Paris; and among the most beautiful specimens of ancient art are the painted windows in the cathedral church of St. Michel and St. Gudule, at Brussels.

Four kinds of glass painting have been practised in England from the eleventh century; the first was the mosaic, in which white or stained glass only was used, such designs as were required being hatched and smeared on the pot-metal, in enamel brown; this method is described by Theophilus: the flesh was of a tan colour; the ornaments were commonly taken from the illuminated MSS. (See Theophilus, *Diversarum Artium Schola*, or the translation

GLASS FOR TELESCOPES

of Robert Hendrie, *An Essay upon various Arts* &c. London 1847.) In the fourteenth century a great advance was made, so that various colours could be got on the same piece of glass, by means of a yellow stain from calcined silver on white or coloured metal; ruby was always coated. During this century and the following, the flesh is generally white, and the hair yellow—this was the mosaic-stain method. In the sixteenth century enamel painting was introduced, in which ordinary enamel colours were painted on white glass; giving two additional methods, the pure enamel, and the mosaic enamel, i.e. when coloured pot-metal was used instead of the white to paint on. There are thus four distinct methods of glass painting, the *mosaic*, the *mosaic stain*, the *enamel*, and the *mosaic enamel*, the last being the ordinary method of the present day, though the Sévres painters still produce pure enamel paintings. William of Marseilles (1475-1537) has the credit of having been the first distinguished enamel painter on glass, and he is also said to have introduced the method of *abrasion*, producing a variety of effects by partially rubbing off the coat from coated glass. Norman and early English windows are *mosaic*; in Gothic work the *mosaic stain* prevails; and in Renaissance and Cinquecento glass, the *enamel* and *mosaic enamel* are the exclusive methods applied. There is a method now in practice of embossing or etching glass by means of asphaltum and fluoric acid; light and shade may be effected by this process, by graduating the *biting in*. (Lasteyrie, *Histoire de la Peinture sur Verre* &c. en France, Paris 1838; *An Inquiry into the Difference of Style in Ancient Glass Painting*, by an Amateur, Oxford 1847; Mrs. Merrifield's *Original Treatises* &c. London 1849; Gessert, *Rudimentary Treatise on Painting on Glass*, &c. London 1851.)

Glass, Soluble. When glass is fused with excess of potash or soda, compounds are obtained which are more or less soluble in water, and have been applied to various useful purposes. When 8 parts of dry carbonate of soda, and 15 parts of white sand or powdered flint are fused together, a glass is obtained which is soluble in about 6 parts of boiling water. This solution has been used to arrest the decay of some building stones, and also for the purpose of diminishing the combustibility of wood, canvas, and similar materials, and more especially of theatrical scenery; it prevents its burning with flame, by forming a glaze upon the surface.

Glass for Telescopes. Till lately, English artists had failed in producing large discs of glass for the formation of object-glasses for telescopes; all the large object-glasses in the public and private observatories being of foreign manufacture. Since the duty has been taken off glass, considerable energy has been shown in England with respect to this branch of manufacture; and Messrs. Chance & Co. of Birmingham have succeeded in manufacturing a disc of pure glass twenty-nine inches in diameter,

whose thickness was two and a quarter inches, and weight 200 lbs. This disc was produced at the Great Exhibition of 1851, and was subjected to a very severe examination for the purpose of detecting defects arising from striae, tension arising from imperfect annealing, bubbles, &c. The only serious defect which was detected after a very lengthened examination, was the existence of a group of striae occupying a space of about six inches and a half in length, and two inches and a half in breadth, beginning at about one inch and a half from the edge, and having its longer dimension directed towards the centre. It was found that if it were ultimately thought necessary to sacrifice the defective portion, a disc of absolutely pure glass of at least twenty-two inches, or probably even of twenty-five inches in diameter, would still be left.

Glassites. [SANDMANIANS.]

Glauber Salt. The name given to sulphate of soda, in honour of the German chemist Glauber, by whom it was made by the action of oil of vitriol on common salt; he called it *sal mirabile*. This salt also exists native, when it forms efflorescent crusts of a greyish or yellowish white colour.

Glauber's Secret Sal Ammoniac. Sulphate of ammonia; a salt first described by Glauber.

Glauberite. A native double sulphate of lime and soda, occasionally associated with rock salt.

Glaucine. A crystalline salifiable alkaloid, occurring in the leaves of the *Glaucium luteum*.

Glaucolite (Gr. γλαυκός, *azur*, and λίθος, *a stone*). A blue-green mineral from near Lake Baikal, in Siberia: it is a silicate of alumina, lime, and potassa.

Glaucoma (Gr. from γλαυκός). A disease of the eye, supposed to arise from dimness of the vitreous humour, and giving it a bluish green colour.

Glaucinite (Gr. γλαυκός). A constituent of the *greensand* formation; it is also sometimes found in the cavities of certain trap-rocks. Under the name of *green-earth* it is used as a pigment. It is a hydrated silicate of iron and alumina with a variable amount of alkalis.

Glaucopictine (Gr. γλαυκός, and πικρός, *bitter*). An alkaloid occurring with *glauoine* in the *Glaucium luteum*.

Glaucopsis (Gr. γλαυκώπις, *grey-eyed*). A genus of Passerine birds established by Forster, and including certain species remarkable for the presence of fleshy wattles attached to the base of the beak; whence they are commonly termed *wattle-birds*. Temminck characterises the genus as follows: Bill moderate, strong, and thick, with the base enlarged towards the commissure; upper mandible convex, vaulted, curved towards the end, and without any notch; lower mandible following the curvature of the upper, straight below, hidden in part by the sides of the upper mandible. Nostrils basal, lateral, round, partially closed by a large membrane, and entirely hidden by curled feathers advancing from the

forehead. Feet robust, the tarsi longer than the mid-toe; toes nearly of the same length; the base of the inner toe, and nearly the whole of the outer toe, attached to the middle toe. Wings short; the first quill short, the three following graduated, and the fifth the longest. Tail long and graduated.

Glaucous (Gr. γλαυκός). In Botany, sea-green; a term used in describing the colour of bodies, to denote a dull green passing into blue. Also used in describing the polish of bodies, to denote their being covered with a fine bloom of the colour of a cabbage leaf. *Glaucouscent* is the diminutive of this.

Glaucus. In Greek Mythology. [SARFÉDOR.]

GLAUCUS. In Zoology, the name of a genus of Nadibranchiate Molluscs, remarkable for their beautiful azure tint. The species of *Glaucus* are found in the warmer latitudes floating in the open sea.

Glaze (another form of the word *glass*). The operation of covering earthenware or porcelain with a coating of vitrified matter is called *glazing*. It usually consists of oxide of lead, salt, or pulverized felspar, according to the nature of the base; the lead glaze being used for earthenware and pottery; the salt glaze, for the commoner descriptions of stoneware; and the felspar glaze for porcelain or china. [GLASS; POTTERY.]

Gleaning (Fr. glaner). The practice of collecting corn left in a harvest field after the harvest has been carried. The Levitical law (Lev. xix.; Deut. xxiv.) ordained that the corn so left should be for the poor. The right of the poor to glean is, however, not admitted in the English common law.

Glebe (Lat. gleba, *arable soil*). In Law, church land; usually taken for that which is annexed to a parish church of common right, and belongs to the parson or vicar.

Glechoma (Gr. γλήχων, *a sort of thyme*). The Linnæan name for the wild plant now more usually called *Nepeta Glechoma*, and known under the popular name of Ground Soy. It furnishes a favourite popular remedy for coughs.

Glee (A.-Sax. glig, gliv, *music, sport*). In Music, a composition for voices in three or more parts. The subjects of the words are various, being gay, grave, amatory, pathetic, or bacchanalian. It may consist of only one movement, but usually has more.

A glee is distinguished from a madrigal, in that the former is sung with one voice only to a part, but the latter with several, like a chorus.

Glee-man. Itinerant minstrels were so called by the Anglo-Saxons; by the Latin writers of the middle ages they are termed *joculatores*. The name appears to have been supplanted by the Norman *minstrel*, shortly after the Conquest.

Glenoid (Gr. γληνοειδής, *socket-like*). A term applied in Anatomy to certain articular surfaces of bones: thus the surface of the scapula which articulates with the head of the

GLIADINE

humerus is called the *glenoid cavity* of the scapula or blade-bone. The same term is also applied to the surface which receives the articular head of the lower jaw.

Gliadine (Gr. γλία, *glue*). A chemical term applied to one of the constituents of the gluten of wheat.

Glires (Lat. pl. of *glis*, a dormouse). The Linnæan name of the order of Mammalia distinguished by two long chisel-shaped incisors in each jaw. [RODENTIA.]

Globe (Lat. globus). A round body, or sphere; a term commonly applied to the earth. The term *artificial globe* is more particularly used to denote a globe of metal, plaster, paper, &c., on the surface of which a map of the earth or of the celestial constellations is delineated, with the principal circles of the sphere. In the former case it is called the *terrestrial*, in the latter the *celestial globe*. Artificial globes are used for the purpose of conveying to children the first ideas of the figure and rotation of the earth, of latitude and longitude, and the situation of places with respect to each other, and to the sun at the different seasons of the year. It is usual to employ them also for the purpose of solving mechanically a few elementary problems of astronomy, relative to the difference of the hour of the day at different places, the times of the rising and setting of the sun, the limits of the visibility of eclipses, &c.

Globular Chart. A delineation, on a plane, according to the method of *globular projection*, of any part of the earth's surface. The method was proposed by Lahire. [MAP; PROJECTION.]

Globular Sailing. [GREAT CIRCLE SAILING.]

Globulariaceae (Globularia, one of the genera). A small natural group of shrubby or herbaceous perigynous Exogens, inhabiting the hot and temperate parts of Europe, combined by Lindley with the *Sclaginaceae*, an order of the Echioal alliance. Their sensible properties are bitter tonic and purgative.

Globuline. A term given by Kieser to the green globules lying amongst the cells of cellular tissue. This word has been applied by Turpin, a French phytologist, to all minute vesicular granules of a vegetable nature, which he considers the organic elements of vegetation. It is either cellular or vesicular tissue in a young state and disintegrated, or granules of starch, or particles of colouring matter collected into microscopical balls. The term *globuline* has also been applied to a modification of albumen found in the humours of the eye, and by some physiologists to the colourless part of blood corpuscles.

Glochis (Gr. γλωχίς, a projecting point). A form of hair occurring in plants, forked at the apex: a *barb*.

Glorify (Lat. gloria). In Painting and Sculpture, a nimbus or circle, either plain or radiated, surrounding the heads of saints, &c. It was used by the Greeks and Romans for the heads or statues of divinities or deceased emperors. [AUREOLA.]

GLUCINUM

Gloss (Gr. γλῶσσα, *tongue*). In the *Rhetoric* of Aristotle, this word is used in the sense of a foreign, obsolete, or otherwise strange idiom; which, when judiciously employed, he reckons among the ornaments of style. From the sense of 'something requiring interpretation' the word came to mean the interpretation itself; strictly, of a single word or phrase. In the twelfth century, the comments or annotations of learned jurists on passages in the text of the Roman law were denominated *glosses*; when these extended to a running commentary, they were termed an *apparatus*. The glosses were collected by Accursius in the thirteenth century, and from that period they formed for a long time a body of authority reckoned equal or even superior to the text itself.

Glossary (Lat. glossarium). A dictionary of difficult words and phrases in any language or writer; sometimes used for a dictionary of words in general. Of all the works published under the title of *glossary*, the most celebrated is the *Glossarium Medicæ et Infimæ Latinitatis* of DuRoi. The best edition of this great work is that by Carpenter, in 6 vols. folio, 1733—1736. Carpenter's *Supplement*, in 4 vols. folio, 1766, is an indispensable addition.

Glossopetres (Gr. γλῶσσα, *tongue*, and πέτρα, *rock*). The small teeth of certain fishes.

Glossitis (from *Glossa*, the river Clyde). A white mineral from the vicinity of Glasgow. It is a hydrated silicate of lime and magnesia.

Glossitis (Gr. γλωττίς). The superior opening of the larynx or windpipe.

Gloves (A.-Sax. glof). Well-known articles of dress used for covering the hands. The practice of covering the hands with gloves has been almost universal from time immemorial. In the middle ages, gloves constituted a costly article of dress, being often highly decorated with embroidery and precious stones. In the age of chivalry it was usual for the soldier who had gained the favour of a lady to wear her glove in his helmet; and, as is well known, the throwing of a glove upon the ground was the most usual mode of challenging to duel. This latter practice prevailed as early as the year 1245.

Glow-worm. [LAMPYRIS.]

Gloxinia (after Dr. Gloxin, a botanist of Colmar). Among the more popular of hot-house flowers are the many forms of this genus of *Genecræa*, well known to gardeners by their foxglove-shaped flowers of varied colours each standing on a separate stalk—in some forms with the opening of the tube directed downwards; in others (which have originated in a freak of nature) standing erect. These plants are among those which generate buds from fragments of their leaves, under the hands of the cultivator.

Glucic Acid. *Kalisaccharic acid*. A body formed by the spontaneous decomposition of combinations of grape sugar with alkalis.

(Gr. γλυκύς, from the sweet taste of its salts). The metallic base of the earth glucina, discovered by Vauquelin in

GLUCOSE

1798, and hitherto only found in a few rare minerals. The metal, which is of a dark grey colour, was first obtained in 1828 by Wöhler; he procured it by acting upon the chloride of glucinum by potassium. The equivalent of glucinum is 7, glucina being represented as a sesquioxide = G_2O_3 .

Glucose. [GRAPE SUGAR.]

Glucosides (Gr. γλυκός). Natural combinations of grape sugar with other neutral organic bodies.

Glue (Gr. κόλλα, Lat. gluten). Glue is prepared from the clippings of hides, hoofs, &c. These are first washed in lime water, and afterwards boiled and skimmed; the solution is then strained through baskets, and gently evaporated to a due consistency; then cooled in wooden moulds, cut into slices, and dried upon nets. Good glue is semitransparent, deep brown, and free from spots and clouds. When used, it should be broken in pieces, and steeped for twenty-four hours in cold water, which causes it to soften and swell; the soaked pieces are then melted over a gentle fire, or, what is better, in a water bath, and in that state applied to the wood by a stiff brush. Glue will not harden in a freezing temperature, the stiffening depending upon the evaporation of its superfluous water. The chemical properties of glue are those of an impure *gelatine*.

Glume (Lat. gluma, the husk of corn). In Botany, the exterior series of the scales which constitute the flowers of grasses. The inner series, commonly called *pales* or *palea*, are sometimes called *Glumella*, and the term *Glumellula* is applied to the hypogynous scale found in the flowers of this tribe of plants.

Glut. In Political Economy, such a production of any commodity as is temporarily in excess of the demand.

It is the object of every producer to anticipate the demand for his product; and, as a rule, supply and demand coincide. But there may be, and constantly are, errors in calculation inducing an over-production of some manufactured or accumulated commodity; or the seasons may be so favourable as to induce a large depreciation in the value of existing stocks, and even to lower the prices of articles below the ordinary cost of producing them. Such occasional circumstances are more likely to arise when any hindrance is put upon the natural tendencies of the market, or when the anticipations of the producer are made difficult by legislative acts, such as protective measures, prohibitions and taxes on exportation, bounties and the like.

Over-production cannot be general, but only special. If everyone produced more, everybody would purchase more, and matters would by this very fact be righted. Indeed, the tendency of mechanical and agricultural improvement is to induce greater general productiveness, and thereupon to bring commodities more and more within the reach of consumers. The dread, therefore, of what has been called a *general glut* is wholly irrational, though it has often

GLYCERIA

induced hasty legislative action, and serious loss to those whom the administration has attempted to assist. Nor can a special glut last long. Persons will not long produce at a loss. The capital which had previously been diverted into unprofitable channels is directed to other employments, and comparative scarcity restores prices. There is obviously a tendency towards equal profits in all occupations; and if action be free, no calling can appropriate exceptional advantages. A fallacy in terms similar to that of general glut, is contained in the hypothesis of a general rise or fall in values. [VALU.]

Gluteal (Gr. γλουτός, the buttocks). Of or belonging to the buttocks: as *gluteal muscles, arteries, &c.*

Gluten (Lat.). The viscid elastic substance which remains when wheat flour is wrapped in a coarse cloth, and washed under a stream of water, so as to carry off the starch and soluble matters. Gluten exists in many grains, and occasionally in other parts of vegetables; but it is a characteristic ingredient in wheat, giving wheat flour its peculiar toughness and tenacity, which particularly fits it for the manufacture of bread, and for viscid pastes, such as macaroni and vermicelli. There is generally more gluten in the wheat of warm climates than of cold; hence the excellence of wheat grown in the south of Europe for the manufactures just mentioned. Gluten contains nitrogen, and has consequently been called the *vegeto-animal principle*: it yields ammonia when subjected to destructive distillation, and the vegetables which contain it give out a peculiarly disagreeable odour during their putrefaction. Sulphur is also one of the ultimate components of gluten. Raw gluten appears to contain several azotised principles, such as vegetable fibrine, caseina, &c., but all closely allied in ultimate composition, which may be represented by—

Carbon	55
Hydrogen	7
Oxygen (and Sulphur)	22
Nitrogen	16
	100

Gluteus (Gr. γλουτός, the buttocks). The large and thick muscle upon which we sit, and which serves to extend the thigh by pulling it directly backwards. It also assists in its rotatory motion.

Glutton (from the same root with Lat. glutio, I swallow, and gula, the throat, Sansc. gala). The name of a carnivorous plantigrade quadruped (*Gulo arcticus*); also applied by some micrographers to a diaphanous species of Naïa.

Glyceria (Gr. γλυκερός, sweet). A genus of Grasses found in wet situations, represented in our own Flora by *G. striata* and one or two other species. *G. striata* is called Ma Grass, and its seeds are collected in countries, and prepared for sale under the name of Manna Croup.

GLYCERIC ACID

Glyceric Acid (Gr. γλυκός). A non-crystalline acid, produced by the action of nitric acid on glycerine.

Glycerine (Gr. γλυκερός). A sweet substance evolved in the process of saponification. It was originally observed in the formation of common plaster by boiling oil with oxide of lead and water. It has now become an article of commercial manufacture, and is used in certain pharmaceutical preparations: it is principally supplied by the wholesale manufacturers of stearine candles, who obtain it in large quantities as a product of the decomposition of fatty matters. It is represented by $C_3H_5O_3$.

Glyceryl. The radical of glycerine = C_3H_7 .

Glycine (Gr. γλυκός, sweet). A genus of *Leguminosæ* to which was formerly referred a very handsome woody creeper, much used for training on walls and houses, which it decorates in spring with its pendent racemes of lilac pea-shaped blossoms. This species, *G. frutescens*, is now called *Wistaria frutescens*.

Glycocoil (Gr. γλυκός, and κόλλα, glue). *Glycocoin*. A sweet crystalline body produced by the action of alkalies on gelatine.

Glycol. A sweetish viscid liquid soluble in water and alcohol. Its composition is $C_2H_4O_2$, so that it differs from alcohol in containing two more atoms of oxygen.

Glycolic Acid. A crystalline body derived from glycol by direct oxidation.

Glycyrrhiza (Gr. γλυκύριζα, having a sweet root). The Liquorice of the shops is the produce of a plant of this genus of *Leguminosæ*, called *G. glabra*. It is a strong-growing plant, with thick deeply-penetrating roots, from which the demulcent extract is obtained by slicing the root, boiling it in water, and straining and evaporating the liquor. The prepared extract is popularly called Spanish Liquorice, from its being largely imported from Spain. In Italy it is prepared from an allied plant, *G. echinata*.

Glycyrrhizin. The peculiar saccharine matter of the root of *Glycyrrhiza glabra*, or common liquorice.

Glyph (Gr. γλυφός, a notch). In Architecture, a vertically sunken channel. From their number in the Doric order, they are called *triglyphs*.

Glyphography (Gr. γλύφω, I engrave, and γράφω, I draw). A method of engraving, by which drawings are made through a thin whitened wax ground laid on a blackened copper plate, the thickness of the wax ground forming the depth of the engraving.

Glyptic (Gr. γλύφω). In Sculpture, a term denoting the art of curving in stone or any other hard substance.

Glyptodon (Gr. γλυπτός, carved, and ὀδούς, a tooth). The name of an extinct gigantic quadruped belonging to the family of Armadillos (*Dasypodidae*), and covered, like them, with a tessellated osseous armour. It is distinguished from the existing armadillos not only by its size, which equals that of the rhinoceros, but by its teeth, which are longitudinally fluted, whence its generic name.

GNEISS

Glyptotheca (Gr. γλυπτός, and θήκη, a store). A building or room for the preservation of works of sculpture; a word adopted by the Germans, as in the instance of the celebrated Glyptothek at Munich, constructed for the late king of Bavaria, Ludwig I., by Leo von Klenze, in 1816-30. It is profusely decorated with frescoes by Peter von Cornelius.

Gmelinite. A hydrated silicate of alumina, potash, and peroxide of iron; named after Gmelin, the mineralogist. It has also been called *Hydrolite*, from the quantity of water which it includes.

Gnaphalium (Gr. γναφάλιον). The plants of this genus of *Compositæ* are amongst those called *Everlastings*. It formerly included most of those met with in gardens; but they are now distributed in several other genera, of which the principal are *Helichrysum* and *Antennaria*.

Gnat. [CULEX.]

Gnathidia (Gr. γνάθος, a jaw). A technical term in Ornithology for the lateral parts or rami of the mandible or lower jaw, which are joined to the cranium behind, and meet in front at a greater or less angle.

Gnathotheca (Gr. γνάθος, and θήκη, a sheath). In Ornithology, the horny or cutaneous integument of the beak.

Gnawers. In Zoology. [RODENTIA.]

Gneiss (Ger.). Gneiss is generally described as stratified granite. It is, in fact, composed of the same materials as granite, namely, quartz, felspar, and mica; but instead of the mass being a multitude of crystals embedded in a base, the whole being compact and possessed of neither cleavage nor foliation, it is, on the contrary, arranged in parallel plates, almost like strata. Gneiss varies exceedingly in its mechanical state, and admits of great modifications, consistent with its metamorphic origin.

Gneiss, when the mica is abundant and the felspar rare, often passes into *mica schist* or *mica slate*, which consist theoretically of mica and quartz alone. The difference between true gneiss and the two rocks thus named is neither very considerable nor very clear. One passes into the other. The whole group of schistose rocks must be regarded as, to some extent, related; and the following illustrations are sufficient to make this clear.

Gneiss and mica-slate often form mountain masses in association with each other and with the varieties of granite. The former is seen singularly contorted upon the coast of Lewes; and mica-slate rock is associated with the serpentine of Cornwall, and is seen in great perfection among the Scotch granitic scenery, more especially in the vicinity of Dunkeld, and in extraordinary magnificence in the lofty mountain of Benmore. Ben Lawers, on the north of Loch Tay, and many of the neighbouring mountains, furnish highly instructive specimens of granite passing into gneiss, mica-slate, and chlorite-slate. About three miles south of Dunkeld, stratified rocks may be seen incumbent upon chlorite-slate, gradually passing into a

GNETACEÆ

fine grey roofing slate, and this recumbent upon mica-slate. The peculiar and differing dip of the respective strata, the singular manner in which they are pierced and traversed by veins of felspar and quartz, and their association with micaceous iron, are circumstances highly interesting in respect to the origin of hypogene rocks; and the beauty and magnificence of the district in regard to scenery is not less than its diversified geological peculiarities.

Gnetaceæ (Gnetum, one of the genera). One of the few orders of Gymnogenous plants commonly called Joint Firs; *Ephedra*, one of the genera, consisting of jointed plants, with the aspect of *Equisetum*, but of a woody character. The order has been known generally by its stems being jointed at every node; but latterly the curious *Welwitschia mirabilis* has been associated with it, and in this there is only a short thick table-like trunk or stem, with a fungoid upper surface, and a pair of long simple leaves, produced at the time of germination, and remaining alone through the life of the plant. There is a branched inflorescence bearing cones, arising from the truncated upper part of the stem, which rises but a foot or two above ground, its two only leaves resting on the surface.

Gnome. A name given by the fanciful writers of the Cabalistic school to that class of elemental spirits which were said to inhabit the earth. Their name is more properly *Gnomons*, from the Greek γνῶμων, *knowing, cunning*.

Gnomic Poets (Gr. γνομικός, *dealing in maxims*). Greek poets, whose remains chiefly consist of short sententious precepts and reflections, are so termed in classical bibliography. The principal writers of this description, of whom a few fragments are extant, are Theognis and Solon, who lived in the sixth century before the Christian era. With them Tyrtæus and Simonides are joined by Brunn in his edition (*Poetæ Gnomici Græci*, Argent, 1784), although these writers have little of a gnomic character. The metre of these poets is elegiac.

Gnomon (Gr. γνῶμων). In Dialling, the style whose shadow marks the hour; generally it denotes a rod or pillar from whose shadow the altitude or position of the sun may be determined. Gnomons were probably the first astronomical instruments; and they appear to have been much in use among the Egyptians, the Chinese, and even the Peruvians. (Goguet, *Origine des Loix*.) It is evident that observations of this kind cannot give the sun's altitude with much exactness. The shadow is never so well defined that its limits can be ascertained with astronomical precision; besides, the observation requires to be corrected for parallax, refraction, and the sun's semi-diameter—elements which can only be determined by means of instruments of a very superior description to the gnomon, and which, consequently, render the latter useless. The astronomer Ulug-Beg, about the year 1437, erected a gnomon at Samarcand, the height of which was 165 Paris feet.

GNOSTICISM

In Geometry, a gnomon signifies the part of a parallelogram which remains when one of the parallelograms about its diagonal is removed; or the portion of the parallelogram composed of the two complements and one of the parallelograms about the diagonal. The term is seldom used, except in Euclid's *Elements*.

Gnomonic Projection. [PROJECTION.]

Gnomonics. The art of constructing dials. [DIAL.]

Gnosticism (Gr. γνωστικός, from γνῶσις, *knowledge*). A philosophical system of religion which prevailed in the East during the four first centuries of our era, and exercised great influence upon Christian theology, giving birth to numerous heresies, and insinuating itself even into the writings of the most orthodox fathers. In its leading principles this system seems to point to the Oriental philosophy as its genuine parent; but it is objected to this solution that the fathers refer it, together with the errors similarly introduced by Platonism, to a Greek origin, and appeal to the cosmogonies of Hesiod and others as the real exemplars from which it is imitated. It is to be remarked, however, that the fathers were universally ignorant of the Oriental philosophy; from which we may conclude that their opinion upon such a point is not necessarily decisive. A modern solution conceives Alexandria to have been the central point to which the speculations of the Greeks and the Orientals converged, and from which they frequently re-issued, after having undergone the process of fusion into a common mass. But although it is certain that Alexandria was, during the time we have spoken of, a celebrated resort of Gnostic opinions, both within and without the church, the close agreement of the leading principles of Gnosticism with those of the Zoroastrian philosophy seems to point to a common tradition, at once very ancient and very widely spread.

The grand principle of this philosophy seems to have been an attempt to reconcile the difficulties attending upon the existence of evil in the world. Evil, it was supposed, being the contrary of good, must be contrary to, and therefore the opponent of, God: if the opponent of God, then independent of Him and coeternal. From the many imperfections which are involved in all outward and sensible objects, it was held that matter must contain in itself the principle of all evil. The human soul, on the contrary, which aspires after and tends to a higher and more perfect development, was held to be the gift of the Supreme Deity, imparted to man for the sake of fighting against the material principle, and with the prospect of finally subduing it. From the Supreme God on the one hand, and matter on the other, succeeding philosophers produced various fanciful genealogies of superior intelligences, under the name of *Æons*—a Greek word signifying properly periods; thus representing these divinities themselves by a name expressive of the time and order of their generation. The Demiurgus,

GNU

who formed the world out of matter, appears to have been an *Æon* derived from the evil principle. He was also the God of the Old Testament, who was considered by the Gnostics to be an object of aversion to the One Supreme God, to counteract whose machinations the *Æon* Christ was sent into the world. This is the earlier and simpler system, which is attributed to Simon Magus: the number of the *Æons* was fancifully multiplied in later times, and an extravagant theory of morals founded upon the system. The object of these principally was, as may be supposed, to depreciate the honour due to the body, as being a part of matter, and to elevate the thinking faculty, or at least to remove it from all consideration of worldly things. The Gnostics imagined that by assiduous practice of certain mental and bodily austerities they could obtain an intuition of the divine nature, and dwell in communion with it; and this part of their system is adopted to a considerable extent by Clemens Alexandrinus, whose opinions, as expressed in his *Pædagogus*, are very similar to those of a Pietist of more modern times.

The Gnostics split in process of time into various sects, distinguished rather by their different cosmogonies than by any variation in principle. Of these the principal were founded by Carpocrates, Basilides, Tatian, and Valentinus. The system did not survive the fourth century, although its spirit continued for some time longer to colour the Christianity of the East. The Christians seem sometimes to have adopted the general designation of Gnostics. (Burton's *Bampton Lectures*; Neander; Gieseler, *Text-book of Eccl. Hist.*; Riddle's *Christian Antiquities*; E. Bunsen, *Hidden Wisdom of Christ*; King's *Gnostics and their Remains*.)

GNU. The *Antelope Gnu* of Linnaeus, a large bovine antelope, which is found in herds in the arid deserts near the Cape of Good Hope. Three species are known.

Goat (Old Norse, *geit*). The English name for the well-known ruminant of the genus *Capra*. The goat is characterised by its long horns, which are rounded posteriorly, angular on the anterior edge; transversely rugose, rising at first perpendicularly, afterwards bending outwards and a little backwards. It is clothed by long hair, which, in the Cashmere breed, is soft and fine, and forms the staple of the celebrated shawls of that name. Beneath the long hair is a soft wool. The female produces two kids at a birth, which derive their nourishment from two teats supported on a large pendent udder. The period of gestation is five months. The milk of the goat is regarded as more easily digestible than that of the cow, and therefore better adapted for the weak and consumptive. The flesh of both the goat and kid is much esteemed in many countries, though it has a peculiar flavour, arising, it is said, from the shrubs and heaths on which they browse. In Portugal and other countries, the goat is used as a beast of draught.

Goat-sucker. The *Caprimulgus europæus*

GOLD

of Linnaeus, a small passerine bird, more correctly termed the Nightjar. [*CAPRIMULGUS*.]

Gobbing. In Mining, the refuse thrown back into the excavations remaining after the removal of the coal.

Gobelin Tapestry. A species of tapestry, so called after Giles Gobelin, a well-known French dyer in the reign of Francis I. His house in the suburb of St. Marcel in Paris is still called the Gobelins. A manufactory for tapestry was established in this quarter by Colbert in 1666.

Goby. A genus of osseous fishes (*Golius*), allied to the cod. The three-spined goby, common in England, is an example.

Godbold's Vegetable Balsam. A quack remedy composed, according to Dr. Paris (*Pharmacologia*), chiefly of honey and vinegar.

Godfather and Godmother. [SPONSORS.]

Godfrey's Cordial. A quack medicine made by infusing 9 ounces of sassafras shavings and of bruised caraway, coriander, and anise seeds each 1 ounce, in 6 pints of water, simmering the mixture till reduced to 4 pints, then adding 6 pounds of treacle, boiling for a few minutes, straining, and adding lastly 3 ounces of tincture of opium. It is often administered as a sedative to children, but is highly dangerous from the opium which it contains.

Godroon. In Architecture, an inverted fluting, beading, or cabling, used in various ornaments or members.

Godwit. [*LIMOSA*.]

Gog and Magog. The names of two symbolical warriors noticed in some books of the Old Testament (Gen. x., Ezekiel xxxviii. &c.). Since the Christian era they have been regarded as nearly synonymous with Antichrist. The author of the Apocalypse (xx. 8) uses the terms to express the nations hostile to Christianity; and Mohammed, in the Koran (21, 96), employs them in an analogous sense, to denote the enemies of Islam. (For the imaginary rampart of Gog and Magog, see Gibbon's *Roman Empire*, ch. xl.) The names Gog and Magog are given to two huge warlike figures which adorn the Guildhall of London.

Goltre. [*BRONCHOCELE*.]

Gola or **Gala.** In Architecture, the same as *Cyma* [which see].

Gold (Ger.). This metal has been known from the remotest ages: it is the *Sol* of the alchemists, who represented it by the circle \odot , the emblem of perfection: its symbol is Au. (*aurum*). It occurs in nature in a metallic state alloyed with silver or copper, and is called *native gold*. It is found disseminated in primitive or igneous rocks, or in the beds of rivers, and in alluvial deposits. The largest supplies have been derived from Australia and California; from Brazil, Mexico, and Peru; from the Ural Mountains; and from some parts of Africa. The rivers of Hungary, Transylvania, and Piedmont have also yielded the metal; and it has been found in Cornwall, Wicklow, and North Wales. Though it generally occurs in small nodules and granules, *nuggets* are some-

GOLD

times found weighing many pounds. It is usually separated from the matrix by grinding and washing, or by amalgamation with mercury.

Gold is of a peculiar yellow colour. It melts at a bright-red heat, equivalent to about 2,000 of Fahrenheit's scale, and when in fusion appears greenish; as it solidifies, it contracts in bulk. Its specific gravity, in its least dense state, after fusion, is 19.2; by hammering and rolling it may be brought up to 19.3 or 19.4. It is so malleable, that it may be beaten into leaves which do not exceed the $\frac{1}{100000}$ th of an inch in thickness; a single grain may be extended over 56 square inches of surface; and it is so ductile that a grain may be drawn out into 500 feet of wire. It may be kept for several hours in fusion without perceptible loss of weight; but when subjected to an intense heat, it affords evidence of volatility. The concentrated mineral acids have separately no action upon pure gold; neither has sulphur nor sulphuretted hydrogen. Chlorine, iodine, and bromine, on the contrary, act upon it; the latter is commonly resorted to for dissolving it is chlorine, generally in the form of nitrohydrochloric acid, or *aqua regia*. If a small portion of leaf-gold is added to a freshly-made solution of chlorine, and the mixture heated, the gold is dissolved, forming a yellow-coloured liquid, any silver that may have been present remaining undissolved. The equivalent of gold is 197; it forms a *protosulphide*, $=\text{Au}_2\text{O}$, and a *peroxide*, $=\text{Au}_2\text{O}_3$, and there are two corresponding chlorides. The *aurocyanide of potassium*, obtained by dissolving cyanide of gold in a solution of cyanide of potassium, is used for gilding silver and copper, and especially for electroplating.

Of the *alloys of gold*, those with copper, mercury, and silver are the most important. With copper gold forms a ductile alloy, of a deeper colour, harder, and somewhat more fusible than pure gold. This alloy, in the proportion of 11 parts of gold to 1 of copper, constitutes our *standard gold*; its specific gravity is 17.167, being a little below the mean. One troy pound of this alloy is coined into 46 $\frac{2}{3}$ sovereigns, or 20 troy pounds into 934 sovereigns and a half. The pound was formerly coined into 44 guineas and a half. The standard gold of France consists of 9 parts of gold and 1 of copper. Standard gold is not affected by nitric acid; but the inferior alloys which are made to imitate gold, consisting chiefly of copper and zinc, immediately decompose it, and set free deutoxide of nitrogen. In testing small articles of jewellery, the metal may be rubbed upon a surface of flint, basalt, or Jasper, so as to transfer a portion to the stone. One or two drops of nitric acid are then placed on the metallic streak. If the article is a base alloy, the metallic appearance is speedily destroyed, and dissolved: if gold, it remains unaffected. Base alloys are frequently plated with gold, and in this case the best method of judging of their quality is by taking the specific gravity, which should be at least 17 for *standard gold*.

Trinket gold is seldom above 15; and the so-called gold chains, ordinarily met with, vary from 11 to 13. Common gilt articles vary from 7 to 9. *Mercury* and gold combine readily, especially when heated. When rich in gold, the amalgam is of a buttery consistence, and may be separated from the more liquid portion by pressure through leather; it then consists of about two parts of gold and one of mercury: the amalgam used for gilding bronze contains about one-eighth of gold. *Silver* and gold mix readily when the fused metals are stirred together. The standard gold at present coined is for the most part alloyed with copper only; previous to the year 1826, the alloy consisted in part of silver, hence its paler colour. To separate the silver from gold, the alloy is melted with a great excess of silver, granulated, and boiled in sulphuric acid, by which the silver is oxidised and converted into sulphate, the metallic gold remaining in the form of a dark insoluble powder, which is afterwards collected, washed, and fused into a button or ingot. In the same way, the small quantity of gold contained in silver coin, which used to pass unheeded, is extracted by sulphuric acid; the recently coined silver will accordingly be found, in most cases, destitute of those traces of gold which are contained in our coin of a date anterior to 1826. When gold and silver are parted by the action of nitric acid, it is necessary, as in the case of sulphuric acid, that the silver should be in great excess; it is otherwise protected by the gold from the solvent power of the acid.

Assay of Gold.—The quantity of standard or other gold used for assay is generally about 8 grains: to this, about three times its weight of pure silver, together with the proper proportion of lead, is added, and the whole subjected to *cupellation*. [CUPEL; LEAD.] The silver and gold are thus thoroughly combined, while the oxides of lead and copper are absorbed by the cupel. The auriferous button is then flattened under the hammer, and after having been annealed, is passed between a pair of small rollers, so as to extend it into a thin riband: it is then again annealed, and coiled up so as to form what is called a *cornet*, which is put into a flask containing about an ounce of hot nitric acid, sp. gr. 1.180, and boiled for about ten minutes, by which the silver is dissolved, and the gold, retaining the form of the cornet, remains: this is again boiled for about twenty minutes in somewhat stronger nitric acid, and then carefully washed and transferred to a small crucible, in which it is heated to redness. When cold, the loss upon the original weight of the sample is carefully ascertained. The weight of the alloy operated upon is generally represented as = 1,000, and the weights used are so adjusted as to give the value of the alloy in thousandths. In the process of gold-assaying, as in that of silver, various errors have to be compensated for, more especially in reference to the traces of copper, lead, and silver which may have been left in the gold.

Tests for the Salts of Gold.—Such of these

GOLD FISH

— are soluble are distinguished by the peculiar purple precipitates which they afford with the mixed chlorides of tin. Potemphosphate of iron, and oxalic and sulphureous acids throw down metallic gold. They are all decomposed by heat, and the residuary gold is easily recognised.

Gold Fish. The *Cyprinus auratus* of Linnaeus, a Chinese species of carp, which has been naturalised in our artificial waters.

Gold Leaf. [GOLD.]

Goldbeater's Skin. The membrane used by goldbeaters, and interposed between the leaves of gold when they have attained considerable tenuity; the intestinal membrane of the rectum of the ox is generally used.

Golden Fleeces. [ARGONAUTS; FLEECE, GOLDEN.]

Golden Number. [CYCLES.]

Golden Rod. A common garden name for the species of *Solidago*.

Golden Rule. In Arithmetic, synonymous with the Rule of Three. The term is now rarely used.

Goldfinch. The common name of our well-known and brightest-plumaged songster; the *Carduelis elegans* of most modern ornithologists, *Fringilla Carduelis* of Linnaeus. This species feeds chiefly on the seed of the thistle and plantain; but builds its nest, which is of the neatest construction, in the fork of a branch of some densely-leaved tree, and lays four or five eggs, of a bluish white, spotted with brown at the greater end. The female is less brightly clad than the male, and the young have a comparatively simple plumage, in which brown predominates.

Golf. A game with a ball and clubs, almost peculiar to Scotland, where it enjoys a degree of popularity equal to cricket in England.

Gomarites. In Ecclesiastical History, the Calvinist divines of the church of Holland in the seventeenth century were so called, from Francis Gomar, a colleague and opponent of Arminius at Leyden. [ARMINIANS.]

Gomphiasis (Gr.). A disease of the teeth, when they loosen and fall out of the sockets. The grinding teeth are also called *gomphioi*.

Gompholite (Gr. γόμφος, a nail; λίθος, a stone). A term applied by Brongniart to the conglomerate rocks of the tertiary series, called by the Swiss *Nägelfels*.

Gompholobium (Gr. γόμφος, and λοβός, a pod). This beautiful genus of Australian Leguminous shrubs has the unenviable notoriety, like its ally *Gastrolobium*, of being a sheep-poisoner, one of the most deleterious species being *G. uncinatum*.

Gomphosis (Gr. γόμφος). A species of junction of bones where they are let into each other, something like pegs in a board, e.g. as in the teeth of mammalia.

Gomuti. The name applied to an Eastern Palm, and to a bristly kind of fibre obtained from it. The Palm is *Saguerus saccharifer*.

Gondola (Ital.). The name given to the pleasure boats used at Venice, where the numerous canals with which it is intersected

GONIOMETER

generally render it necessary to substitute boats for carriages. The gondola is from twenty-five to thirty feet long, and five feet wide in the centre, where a sort of cabin is constructed for passengers. It is sharp-pointed both at the prow and stern, and is rowed by two men called *gondolieri*. The cabins are furnished with black curtains, which give a sombre appearance at a distance. For an accurate description of the gondola, see Lord Byron's *Beppo*, 19, 20.

Gonfanon or **Gonfalon** (Ital.). In Heraldry, a banner; that of the Roman Catholic church carried in the pope's army. The gonfanon or standard-bearer was a high officer in the Italian republics of the middle ages.

Gong or **Tam-tam** (of the Chinese). A species of cymbal, which on being struck produces a very loud sound. According to the analysis of Klaproth, Chinese gongs consist of about seventy-eight parts copper and twenty-two of tin. As this alloy is brittle, and the instrument always exhibits marks of the hammer, it is inferred that the Chinese possess the art of rendering it malleable, and afterwards hardening it. It is struck with a wooden mallet covered with leather.

Goniatites (Gr. γωνία, an angle). A genus of extinct Cephalopods with chambered spiral shells; nearly allied to the *Ammonites*, but differing in having the lobes of the septa free from lateral crenatures or denticulations, so that the outline of these is continuous and uninterrupted. Goniatites are found in the mountain limestone of Yorkshire.

Goniometer (Gr. γωνία, angle, and μέτρον, measure). An instrument for measuring angles, and more particularly the angles formed by the faces of crystals. The instrument, chiefly used by mineralogists, was invented by Dr. Wollaston. It consists of a brass circle graduated on the edge, and furnished

with a vernier, by which the divisions may be read correct to a minute. The circle moves in a vertical plane, and is supported on a stand. The axis of the circle is a hollow tube, within which is a smaller axis, fitting so tightly that when turned round it carries the other axis and consequently the wheel along with it, unless the latter is purposely prevented from moving. The interior axis is furnished with a milled head *a*, and the exterior with a milled head *b*; so that when the head *a* is held and *b* turned, the circle may be moved independently of the smaller axis; and when *b* is held and *a* turned, the smaller axis may be turned independently of the circle. Attached to the end of the smaller axis is a sort of universal joint, capable of being fixed in different positions by means of screws. The crystal to be examined is attached to the joint at *c* by a little soft wax,

and placed so that its edge shall be parallel to the axis of motion; this adjustment is obtained by placing it so that the image of some horizontal object, as the bar of a window, successively reflected from the two faces of the crystal, shall coincide with another horizontal line seen by direct vision. When this adjustment has been made, the instrument is turned till the horizontal object is seen reflected from one of the faces. The smaller axis is then held fast, and the other turned till the index of the vernier points to the zero of the graduated limb. The circle is then turned round, along with the smaller axis, till the same object is seen in the same position by reflection from the other face of the crystal, when the arc passed through by the circle is obviously the supplement of the angle formed by the two faces of the crystal. In order, however, to avoid the need of calculation, the supplements of the angles are marked on the limb, so that the angle to be measured is read off immediately.

Other forms of the goniometer have been proposed by Charles, Malus, and Brewster. (Biot, *Traité de Physique*, tom. iii.; and Brewster's *Treatise on Philosophical Instruments*.)

Goniometry. The measurement of angles. The term is in many respects preferable to *Trigonometry*, by which it is now replaced; for the latter, strictly speaking, signifies merely the measurement of triangles.

Goniatopholis (Gr. γωνία, *angle*, and φολίς, *a scale on a reptile's skin*). A genus of fossil Crocodiles, with subamphicelican vertebrae, which has been found in the Wealden and Purbeck deposits. The teeth have crowns, which are as round and as thick in proportion to their length as in the existing crocodiles and alligators. The name is derived from the peculiar angular form of the scutes, which are found in a fossilised state in the same strata with the bones.

Gonoplax (Gr. γόνυ, *a knee*, and πλάξ, *a plane*). A genus of crabs or short-tailed crustaceans (*Brachyuri*), characterised by the angular, square, or rhomboidal form of their upper crustaceous plate or carapace, and by the length of the eye-stalks. One species (*Gonoplax rhomboides*) inhabits the Mediterranean, and is a good swimmer; but most of the rest of the genus are tropical.

Gonyx (Gr. γόνυ). In Ornithology, the inferior margin of the symphysis of the lower jaw, or the united anterior extremities of the gnathidia.

Good Behaviour, Security for. In Law, a person on sufficient cause shown may be bound with one or more sureties in a recognisance or obligation to the crown before some judicial officer, the recognisance to be void if the person continue of 'good behaviour' for the duration of the recognisance.

Good Conduct Pay. A pecuniary reward to soldiers for good conduct. After three years clear of punishment, a soldier gets an additional penny per diem, and another penny after

each succeeding five years clear of the regimental defaulters' book.

Good Friday. The name given in England to the anniversary of our Saviour's crucifixion. The French and most other European nations substitute the epithet *holy* for *good*: the Germans designate this day *Stiller-freitag*, or *Char-freitag*: the latter appellation being derived from an old word *charen*, signifying *to do penance* or *to suffer*.

Good Will. In Law, the custom, or benefit of habitual patronage by customers, incidental to an established trade or business. It is usually divided into *local* and *personal* goodwill, though generally it partakes of both elements. It is frequently the subject of sale, and usually survives, on the death of a partner, to the other members of the firm.

Goodeniaceæ (Goodenia, one of the genera). A natural order of perigenous Exogens of the Campanal alliance, distinguished particularly by the induplicate corolla, the induplicate stigma and the two or more celled ovary. Some of them are showy garden plants, but they have no very remarkable properties.

Goodgeons, also called **Braces**. Metal eyes bolted on to the stern post of a ship, for the purpose of receiving the pintles of the rudder. They consequently form the immovable portion of the hinges on which the rudder is held suspended.

Goose. [ANAS.]

Gooseberry. A well-known garden fruit, the produce of *Ribes Grossularia*.

Goosefoot. [CHENOPODIACEÆ.]

Gordian Knot. In History, a knot said to have been made by Gordius, king of Phrygia, in the harness of his chariot, so intricate as to baffle every effort to untie it. The oracle having declared that he who untied this knot should be the conqueror of the world, Alexander the Great, as is well known, made the attempt; but fearing lest in the event of his failure it should be considered as a bad omen, he cut it asunder with his sword; and thus, says Quintus Curtius, either fulfilled the oracle or eluded it. Aristobolus, however, gives a different version of the story. (Arrian, book iii. c. 20; and Plutarch, *in vit. Alex.*)

Gordius (Lat.). The hair worm, or *seta equina*, found in stagnant water in Lapland and elsewhere.

Gorge. In Architecture, the same as CAVETTO [which see].

GORGE (Fr.). In Fortification, the gorge of a work is the line joining its inner extremities. [FORTIFICATION.]

Gorget (Fr. gorge, *a throat*). A piece of body-armour, either scale work or plate, for the protection of the throat; it appears to have been first employed early in the fourteenth century. The *camail*, or throat covering of chain mail, which is sometimes called the *gorget of mail*, belonged more to the helmet than to the body armour. In the seventeenth century the gorget was worn without any other body armour.

GORGET

GORGET. A surgical instrument used in the operation of lithotomy.

Gorgoneia. In Architecture, carvings of masks imitating the Gorgon, or Medusa's head.

Gorgonia Nobilis (Lat.). *Corallium rubrum*, or red coral.

Gorgons (Gr. *Gorgones*). In Greek Mythology, fearful beings akin in idea to such monsters as Echidna, Chimera, &c. Homer knows of only one Gorgon, whose head was placed on theegis of Athena. (*Iliad* v. 741.) Hesiod names three, Stheino, Euryalê, and Medusa. The latter, who alone was mortal, and whose face was so fearful that the sight of it turned the beholder into stone, was killed by Perseus.

Gorilla (derived from the African word 'ngwila' or 'ngwyla'; Hanno in his *Periplus* termed the females γορύλλαι). The larger species of chimpanzee, which is found in the neighbourhood of the Gaboon, Danger, and Fernan Vaz rivers. This animal has a greater resemblance to man than either of the five smaller species of the same genus, i.e. the chimpanzee (*T. niger*), the koolocamba (*T. koolocamba*), the nschiego 'mbouré (*T. calvus*), Burton's chimpanzee (*T. vellerosus*), or Aubry's tschego (*T. Aubryi*). The special points in which this resemblance to man is indicated, are: the mastoid processes, which are greater than in most monkeys; the conformation of the foot; the form of the nasal bones; and many minute anatomical points. The animal often reaches the height of nearly six feet; and the enormous ridges on the skull to which muscles are attached, give almost a carnivorous character to its physiognomy. The back is greyish; the under or fore part of the body being black; a reddish brown cap covers the head, whilst a whitish stripe extends over the shoulders. The animal was originally discovered by Dr. Savage at Gaboon, and has been copiously described in the writings of Professor Owen, in the *Zoological Transactions*, and also by Messrs. Duvernoy, Isidore Geoffroy St. Hilaire, and Gratiolet.

Gorse (connected by Mr. Wedgwood with Welsh *gores*, *waste*). [FOREST.] The Common Furze, *Ulex europæus*, sometimes cultivated for the sake of its young shoots, which while soft, or after being crushed by machinery, are given as food to cattle.

Goru Nut. [KOLA NUT.]

Gos-hawk. The *Astur palumbarius* of Cuvier.

Gospel (A.-Sax. Godspell). A word used to signify the whole system of the Christian religion, and more particularly, as the term literally implies, the good news of the coming of the Messiah. The word was also originally applied to the books which contained an account of the life of Christ, many of which were in circulation in the first century of the Christian era, though only four, those of Matthew, Mark, Luke, and John, were admitted into the canon by the council of Nicæa.

Gossip (A.-Sax. God, and sib, *kindred*). This word, now used to denote only a tattler

GOUT

or busybody, was originally applied to sponsors at baptism, from the spiritual relationship in which they stood to the child.

Gossypium (Lat. gossypion). This genus of *Malvaceæ* yields the Cotton-plant, one of the most important of all plants to man. The Cotton-plants are tall shrubs, with lobed leaves, large mallow-like yellow flowers, and somewhat egg-shaped angular pods, the seeds of which are enveloped in a covering of cellular filaments which form the Cotton of commerce. The principal species are *G. barbadense*, *herbaceum*, and *religiosum*; but the Cotton-plant has been so long cultivated and the varieties are so numerous, that their origin cannot be traced with any certainty. One of the most valued sorts is that known as Sea Island Cotton, which appears to have sprung from *G. barbadense*. At the present day, various experiments in hybridising cotton-plants, with the view of improving the staple of the sorts capable of cultivation in particular districts, are being carried on. (*Gardener's Chronicle*, 1864, p. 1085.)

Gothic Architecture. [ARCHITECTURE, GOTHIC.]

Gothic Language. One of the many dialects of the German race, belonging to the Low German class, with a grammar more primitive than the Anglo-Saxon of Beowulf. It is preserved to us in the translation of the Bible made by Bishop Ulfilas in the latter part of the fourth century.

Gouldard's Extract of Lead. A subacetate of lead, obtained by boiling powdered litharge in vinegar.

Gourd (Fr. gourd, courgourde). The species of *Cucurbita* are called Gourds, the Common Gourd being *C. Pepo*, of which there are numerous cultivated varieties. Some Gourds are good for food, either alone as a cooked vegetable, or as an ingredient in soups.

Gously. An old form of harp used by the Slavonians, whose bards were called Gousalas, the poetry which they chanted being styled *gouslo*.

Gout (Fr. goutte: if from the Latin gutta, a drop, this word points to the old medical theory which attributed all kinds of disorders to the settling of a drop of morbid humour on the part affected, as in the phrase *gutta serena* for loss of sight without visible affection of the eye: Wedgwood, *English Etymology*). Gout is a common disease among the higher classes of society, especially among those who indulge in the luxuries of the table, or inherit a disposition to its attack. Females are much less subject to it than males. Medical writers have distinguished several species of gout, and have called the disease in its ordinary form the *regular gout*. The first symptoms of its attack are those of dyspepsia and irregularity of bowels, low spirits, and some fever and restlessness; but these often pass unobserved, till the patient is roused in the night by violent pain in some part of the leg, generally in the vicinity of the great toe,

GOUT

and of one foot only : there is much throbbing and uneasiness, with more or less swelling and inflammation, and the least motion commonly produces great increase of suffering. After some hours the pain and fever abate, perspiration comes on ; the patient falls asleep, and awakes comparatively easy. These fits or paroxysms are apt to return at intervals, and often every evening ; but they decrease in violence, and at length go off, frequently with some decided increase of perspiration or other evacuation : the affected part itches, and the cuticle peels off, more or less lameness or uneasiness remaining. But the fit thus leaves the patient only for a time, and returns at intervals of longer or shorter duration, according to his habit of body and the care which he takes of himself. The attacks not only become more frequent and severe, but last longer, and extend to other limbs ; and when they have been frequently repeated, they leave a permanent stiffness of the joints, upon which *gouty concretions* are often deposited : and if much attention is not paid to the state of the urine, fits of sand and gravel not uncommonly precede or accompany those of gout. Where the disease is of long standing, and the form of it severe, the body becomes maimed and decrepit, and the mind often worn and irritable ; the joints of the feet and hands, and even the larger joints of the extremities, are stiff and nearly immovable ; and the formation of the chalky matter, as it is called, about the joints increases. If we consider the nature of this secretion in the joints, which is *urate of soda*, and the tendency of gouty persons to those morbid states of the kidneys and urine which depend upon excess of uric acid, and even upon the frequent alternation of fits of gravel with those of gout, the question will naturally suggest itself whether gout is not a symptom of what is often termed the *uric diathesis*, and whether the remedies applicable to it may not be beneficial in gout ; and that in many cases they are so, seems to have been amply proved by experience. [CALCULI.] It was once a favourite maxim that the gout was an effort of the system to relieve itself of some peccant matter ; that, therefore, it was to be left almost to itself, and that patience and flannel were the chief remedies. This method still has its advocates, chiefly in consequence of the presumed dangerous results that have sometimes attended more active plans of treatment in causing the revulsion of the gout from the limb to the stomach or head. But though there may be a difference of opinion in regard to certain energetic modes of relieving the disease, no one can object to the adoption of gentle means of quieting the urgency of the symptoms, and to the adoption of such diet and plan of living as appears to diminish the frequency of their recurrence. Warm laxatives, moderate diaphoretics and diuretics, and occasionally opiates, are among the former ; and plain food or vegetable diet, with moderate exercise and tonics, are good preventives. Those, however, who have witnessed the suf-

ferings of a regular paroxysm, and the evils of its duration and repetition, will see the necessity of doing something more ; that is, of speedily quelling the pain and carrying off the attack, if it can be done with any chance of safety and success ; and this experience shows to be often the case, though much care and judgment are undoubtedly requisite in conducting such treatment. With persons of strong and healthy habits, the affusion of cold water is one of the most effective palliatives of the pain and inflammation ; and by its timely application, in proper cases, the most beneficial results have ensued. Another celebrated remedy in this disease, and which by some has improperly been called a *specific*, is *colchicum*, or *meadow saffron*, a due dose of which, taken at bedtime, has carried off the paroxysm. This it often does without any remarkable evacuation, though it sometimes handles the patient severely as a purgative, and nauseates and depresses to an alarming extent. This method of cure must not be unadvisedly and generally adopted ; but in some cases, where gout had been long established, and where the frequency and duration of the fits and their inroads upon the constitution were increasing to a serious extent, and that at an advanced period of life, *colchicum*, carefully administered, seems to have carried off the severity, if not the frequency, of the attacks, and so to have prolonged life. But there are forms of gout, and consequences of gout, the management of which requires the utmost skill and experience : it is sometimes transferred or translated from the limbs to some internal part, in which case it is called *retrocedent gout* ; or it produces sickness, dejection of spirits, fainting, palpitation, and giddiness, as in what is termed *atonic gout* ; or it falls at once upon some internal part, especially the stomach, and is then called *misplaced gout*. In gout of the head and of the stomach the symptoms are often frightfully severe, and the pain excessive ; and as these forms of gout are of most common occurrence in debilitated habits and broken constitutions, they become, on that account, the more difficult to treat : the expulsion of the disease to the extremities is in such cases sometimes effected by ether, brandy, or what are termed *gout cordials*, which generally consist of warm aperient tinctures ; but before these are administered, it must be ascertained that the symptoms are really those of atony. In such cases, putting the feet in warm water has sometimes been serviceable. The moderate use of alkaline remedies, of a vegetable diet, of certain diuretics, and generally speaking the adoption of those plans of regimen and medicine which are useful in the uric diathesis, are also useful in gout ; and everything which tends to repair the constitution generally will lessen the liability to its attacks, and render them more manageable when they occur. The indolent and sedentary must use moderate exercise, and those who habitually over-exert either body or mind must endeavour to tranquillise both : unless such

GOUTY CONCRETIONS

precautionary measures are peremptorily enforced, no gouty person can expect much benefit from physic.

Gouty Concretions. These form in the joints of gouty persons, especially of the toes and fingers, and are sometimes, from their appearance, called *chalk stones*; they are chiefly composed of uric acid and soda.

Government (from Lat. *gubernare*, properly *I steer a ship*, like the Gr. *κυβερνᾶν*). In Politics, a word used in different senses: 1. As the collective body of the fundamental laws of a state: as when the government of a country is said to be monarchical, aristocratical, &c. 2. The body of persons charged with the conduct of the executive in any country: thus, the king or presiding magistrate, the cabinet ministers, chiefs of departments, &c. in every country, form what is commonly styled its government. [LIBERTY.]

Governor. The title of the supreme executive officer in British colonies. He is in all cases appointed by the crown, and has the right of *veto*, i. e. of negating any proposed legislative measure; while his own sanction of any such measure is subject to reversal by the crown at home. In other respects, his functions vary greatly according to the various constitutions of the colonies. The heads of the presidencies of Madras and Bombay in India are also styled *governors*. In the North American Union, the title has been retained, as a relic of the old colonial times, for the chief officer of the executive in each state, who is elected for a term by the people.

Governor of an Engine. A contrivance introduced by James Watt in the steam engine,

by which the motion of the fly-wheel shaft regulates the velocity of the engine, by causing two balls to revolve in such a manner that they open, or close, the passage of the steam from the boiler, by means of a butterfly valve, in proportion to the increase of velocity. Two heavy balls, BB, attached to the extremities of two rods BF, BF, play upon a joint at E, passing through a mortise in the vertical shaft DD. These are united by joints at F to the short rods FH, which again are connected by joints at H to a ring which slides on the shaft DD. A horizontal wheel, W, is attached to DD, having a groove to receive a rope or strap on its rim, by means of which the motion is communicated to DD from a corresponding wheel on some shaft of the machinery to be regulated. It is evident, from the disposition of the rods, that if the balls BB are by any means raised or drawn asunder, the extremities FF of the rods turning on the pivot E will also be separated, and their distance from the axis increased. This will draw the rods FH in the same direction, and cause the ring or collar H to descend. This ring is connected with the end I of a lever, whose fulcrum is at

GRACE

G, and whose other extremity K is connected by some means with the part of the machine which supplies the power. Suppose now the velocity from any cause to undergo a sudden increase; by reason of the increased centrifugal force arising from the whirling motion, the balls BB will recede from the shaft DD, and raise the extremity K of the lever. On the other hand, if the velocity is diminished, the centrifugal force of the balls will be diminished, they will fall by their own weight nearer the axis, and cause the end K of the lever to descend. When the governor is applied to a steam engine, the rod K I communicates with a flat circular valve V, placed in the principal steam pipe, and so arranged that when K is elevated as far as the divergence of the balls will allow, the opening of the pipe will be closed by the valve V, and the passage of steam entirely stopped. On the other hand, when the balls subside to their lowest position, the valve will be entirely open. Thus, when the velocity is increased, the supply of steam is checked; and when it is diminished, the supply of steam is immediately increased; by which means a uniform proper velocity of the machinery is maintained. [REGULATOR.]

Governor-General of India. The chief executive officer of that dependency: appointed by the crown, and usually serving for a term of five years. His powers are very high, extending to the declaration of war and peace, and making leagues and alliances; but subject in all matters to the control of the crown, through the Secretary of State for India. Almost all acts of state are performed by the governor-general 'in council;' that is, with the advice of his council, although not necessarily in accordance with the majority. This council consists of five ordinary members, three of whom must have been 'civil servants,' and the commander-in-chief as an extraordinary member. When the council meets for purposes of legislation, certain 'additional' members are summoned under the provisions of the Indian Council Act of 1861. But the governor-general is authorised by the same Act, in case of emergency, to make regulations of his own independent authority, having force of law.

Grabs. Small armed vessels used on the coast of Malabar.

Grace (Lat. *gratia*). In the language of the New Testament, is primarily the favour and love of God towards any person: thence it comes to be used in various derivative senses, being put generally for all the extraordinary means and assistances with which men are endowed to bring them to salvation. The term is used, further, for the good actions and dispositions of men, which may be supposed to be derived from the operation of the grace of God in the first instance. [PELAGIANISM.]

GRACE. In the Fine Arts, a quality arising from elegance of form and attitude combined. A figure may be just in its proportions, its parts and members may be all perfectly regu-

GRACE, DAYS OF

lated, yet it may be deficient in grace. It is scarcely possible in words to express this quality, yet it is constantly seen in nature; and it is scarcely possible to contemplate a picture by Raphael without feeling its power.

Grace, Days of. In Commercial Law, certain days allowed by the custom of merchants to be added to the time requisite for presentment of a bill. Thus, if an instrument drawn in this country be payable 'at certain time after date,' three days of grace are added: a bill drawn on August 27, payable 'two months after date,' is therefore due on October 30. So if a foreign bill be drawn at one, two, or more *usances*, the days of grace are added to the *usance*. The *usance* between London and Paris is one calendar month: a bill drawn in London on Paris, 'at one *usance*,' on Jan. 2, is consequently due on February 5. The number of days of grace varies in different countries. In France none are allowed.

Grace at Meals, The Saying of. A Jewish custom sanctioned by the practice of our Lord, and adopted by the early Christians. A custom of beginning meals by invocations was common in classical antiquity. (Livy xxxix. 43; Quintil. *Declam.* 301.)

Graces (Lat. *Gratiæ*). In Latin Mythology, the Graces answer to the Greek *CHARITES* [which see].

GRACES. In Music, ornamental notes attached to principal ones, such as the *APPOGIATURA*, *SHAKE*, &c. [which see].

Gracioso (Ital.). The buffoon; a favourite character on the Spanish stage.

Gracula (Lat. *graculus, a daw*). A genus of Dendrostrafal Passerine birds, characterised by a moderately long, slightly arched, and notched beak; nostrils situated anterior to the base of the beak, oblong, open, and notched; tongue with a short apex, often bifid. One species of this genus (*Gracula tristis*, Cur.) is a native of India, and has been imported into the islands of Bourbon and Mauritius, where it is held in the highest estimation for the services it performs in checking the increase of locusts. The bird commonly called the mino grackle (*Gracula religiosa* of Linnaeus) is the type of the genus *Eulabes* of Cuvier.

Gradatory (Lat. *gradus*). A term applied in Mammalogy to the extremities of a quadruped which are equal, or nearly so, and adapted for ordinary progression on dry land. In Ornithology, the *pides gradarii* are those in which the whole tibia is covered with feathers.

Grade (Lat. *gradus, a step*). According to the French method of estimating angles, a grade is the hundredth part of a right angle: each grade is further divided into 100 minutes, and each minute into 100 seconds, so that .0537730 of a right angle denotes 5 grades 37 minutes and 30 seconds, or as it is sometimes written 5° 37' 30". Whence may be deduced an easy method of converting grades into ordinary degrees.

radiant (Lat. *gradior, 1 step or go*). The

GRAFTING

inclination given to a road, canal, or river. The rate of inclination is expressed in England by taking the foot as the unity, and saying that the gradient is one in so many feet as there may be; in the continental style, the unity is always the metre, and the gradient is quoted in subdivisions thereof. Thus in English documents it is said that the gradient would be 1 in 100 feet when the rise, or inclination, is 1 in height to 100 feet base; in continental phrase it would be called a gradient of 0.01m. to 1.00m. Formerly it was thought necessary to employ much easier gradients for the locomotive than some which are now admitted, an inclination of 1 in 200 being then considered to be the maximum inclination that should be allowed, whereas 1 in 33 is considered quite within the limits of practice. The maximum inclination of mail coach roads is taken as 1 in 30; that of country roads as 1 in 20; that of occupation roads as 1 in 8 occasionally: the gradients of river navigation are usually considered to be from 1 in 2,000 to 1 in 1,250, at which rate the navigation of the Rhône was for a long time maintained with considerable profit.

Graduale (Lat. *gradus*). An anthem sung in the Mass of the Roman Catholic church after the epistle. [AMBO.]

Graduate (Lat. *gradus*). One who has taken a degree in a college or university. [DEGREE; COLLEGE; UNIVERSITY.]

Graduated. In Ornithology, when the quill-feathers of the tail increase in length by regular gradations.

Graduation. In Practical Astronomy, the division of circular arcs into degrees, minutes, &c. This is an art which, though depending on the geometrical properties of the circle, requires for its successful execution the application of very great practical skill. For the principles, see Mascheroni, *Géométrie du Compas*; and for the practical part, Troughton's 'Account of a Method of Dividing Astronomical and other Instruments. &c.' in the *Phil. Trans.* 1809, as also his article 'Graduation' in Brewster's *Encyclopædia*.

Graduator. A contrivance for accelerating spontaneous evaporation by the exposure of large surfaces of liquids to a current of air has been termed a *graduator*; and in some salt works, where the brine is strengthened by allowing a shower of it to trickle over faggots, the process is called *graduation*. Vinegar is sometimes manufactured in a kind of graduator, by suffering a mixture of alcohol and water, previously mixed with some ferment, to trickle through a tub filled with beech shavings, through which a current of air is at the same time passing.

Grafting (Fr. *greffe*). In Horticulture, the operation of affixing a portion of one plant to another in such a manner as that a vital union may take place between them. Grafting may be performed both with herbaceous and ligneous plants; but in practice it is chiefly confined to the latter, and more especially to the propagation of esteemed varieties of fruit-trees. A

GRAFTING

grafted plant consists of two parts: the stock or stem; which is a rooted plant fixed in the ground; and the scion, sometimes, but erroneously, termed the *graft*, which is a detached portion of another plant to be affixed to it. The operation of grafting can only be performed within certain physiological limits; but these limits have not yet been absolutely determined.

In general, all the species of one genus may be grafted on one another reciprocally; but this is not universally the case, because the apple cannot be grafted on the pear, at least not for any useful purpose. In general, it may be presumed that all the species of a natural order, or at least of a tribe, may be grafted on one another; but this does not hold good universally. The reverse of this doctrine, however, viz. that the species belonging to different natural orders cannot be grafted on one another, holds almost universally true; and therefore a safe practical conclusion is, that in choosing a stock, the nearer in affinity the species to which that stock belongs is to the scion, the more certain will be the success.

Grafting is one of the most important operations in horticulture, as affording the most eligible means of multiplying and perpetuating all our best varieties of fruit-trees, and many kinds of trees and shrubs not so conveniently propagated by other means. Varieties of fruits are originally procured by selection from plants raised from seed, but they can only be perpetuated by some mode which continues the individual; and though this may be done by cuttings and layers, yet by far the most eligible mode is by grafting, as it produces stronger plants in a shorter time than any other methods.

Grafting is performed in a great many different ways; but the most eligible for ordinary purposes is what is commonly called *splices grafting*, or *whip grafting*. In executing this mode both the scion and the stock are pared down in a slanting direction, and afterwards applied together, and made fast with strands of bast matting, in the same manner as two pieces of rod are spliced together to form a whip handle. To insure success, it is essentially necessary that the alburnum or inner bark of the scion should coincide accurately with the inner bark of the stock; because the vital union is effected by the sap of the stock rising up through the soft wood of the scion. After the scion is tied to the stock, the graft is said to be made; and it only remains to cover the part tied with a mass of tempered clay, or any convenient composition that will exclude the air. The season for performing the operation is, for all deciduous trees and shrubs, the spring, immediately before the movement of the sap. The spring is also the most favourable season for evergreens; but the sap in this class of plants being more in motion during winter than that of deciduous plants, grafting, if thought necessary, might be performed at that season.

Grafting by approach, or inarching, is a mode of grafting in which, to make sure of

GRAIN TIN

success, the scion is not separated from the parent plant till it has become united with the stock. For this purpose the stock and the plant containing the scion must be growing close together; and the scion being drawn to one side, and made to approach the stock, is spliced to it by cutting off a portion of its bark and wood, and a similar portion of the bark and wood of the stock, applying the one to the other so that their alburnums may join, and then making both fast by matting, and excluding the air by clay, grafting wax, or moss. When the scion has effected a vital union with the stock, its lower extremity is cut through, so as to separate it from the parent plant, and it now becomes an independent graft. In this way trees of difficult propagation may be propagated with certainty; while if any of the other modes of propagation, whether by cuttings or grafting, were adopted, a proportion of the cuttings or scions would, in all probability, be lost.

Grafting herbaceous plants differs in nothing from grafting such as are of a woody nature, excepting that the operation is performed when both stock and scion are in a state of vigorous growth. It is less practised than the grafting of woody plants.

Grafting the herbaceous shoots of woody plants—the *greffe herbace* of the French—has been extensively employed in France. The scions are formed of the points of growing shoots; and the stocks are also the points of growing shoots cut or broken over an inch or two below the point, where the shoot is as brittle as asparagus. The operation is performed in the cleft manner; that is, by cutting the lower end of the scion in the form of a wedge, and inserting it in a cleft or slit made down the middle of the stock. The finer kinds of *azaleas*, pines, and firs are propagated in this way in the French nurseries; and thousands of *Pinus Laricio* have been so grafted on *Pinus sylvestris* in the forest of Fontainebleau. At Hopetoun House, near Edinburgh, this mode of grafting has been successfully practised with *Abies Smithiana*, the stock being the common spruce fir.

Grain (Lat. *granum*). By a statute passed in the reign of Edward III. (1266), it was enacted that thirty-two grains of wheat, taken from the middle of the ear and well dried, should constitute a pennyweight, of which there were to be twenty in an ounce. The grain now in use, however, is the 7,000th part of a pound (avoirdupois); in other words, the 70,000th part of the weight of an imperial gallon of water at 62° Fahr., the barometer being at thirty inches. Under the same conditions, a cubic inch of water weighs 252.458 grains. The grain is the unit of our system of weights. [WmONTA.] The French decigramme is about 1.6 English grains, the gramme being = 15.434 English grains.

Grain Tin. The purest kind of tin. The term was formerly applied to the metal obtained from the rounded pebbles of tin stone, called *stream tin*. The peculiar columnar fracture which pure tin exhibits when broken,

is given by heating the ingot till it becomes brittle, and then letting it fall from a height upon a hard pavement.

Grains of Paradise. The seeds of a species of *Amomum*: they are acrid, and said to be the *malagueta pepper* of Africa. They are also called *guinea grains*, and are largely imported from Africa. They are used to give a pungent flavour to spirits, beer, and vinegar. By 56 Geo. III. c. 58 no brewer or dealer in beer shall have in his possession or use grains of paradise, under a penalty of 500*l.* for each offence. An erroneous notion prevails that these seeds are injurious; in Africa they are esteemed a wholesome spice, and used by the natives to season their food.

Grallæ (Lat. *stilts*). The Linnæan name of the order of long-legged wading birds.

Graminaceæ (Lat. *græmēn, grass*). An order of Endogenous plants, commonly called *grasses*, in which the parts of fructification are essentially perfect, although they are in a very unusual state in what may be called their accessory organs. They have neither calyx nor corolla; but, in lieu of them, imbricated scales, called *paleæ* and *glumes*: the latter of which give rise to the name *glumaceous*, often applied to these plants. They are nearly allied to sedges, from which they differ in having the sheaths of their leaves slit and their stems hollow.

The Grasses are widely distributed over the world, including about one in twenty two of all known plants, according to Schouw. They are social plants, forming herbage in temperate climates, and becoming arborescent in the tropics. The order is a most important one, but not uniformly wholesome, for Darnel grass, *Lolium temulentum*, is said to possess poisonous qualities, which are attributed also to the *Festuca quadridentata* of Quito, to *Bromus purgans, catharticus, and mollis*, and to an Indian variety of *Paspalum scrobiculatum*. Several species of Andropogon yield fragrant oils. [GRASS OIL.] The bamboo, *Bambusa arundinacea*, is one of the most useful grasses in warm countries; as also is the sugar cane, *Saccharum officinarum*, in a commercial point of view. The principal cereal grasses cultivated for food are, Wheat, Barley, Oats, Rye, Rice, Indian Corn, Millets, Guinea Corn, and Swamp Rice. The grains of *Coix lachryma* are used as beads under the name of *Job's tears*. Some kinds of grass, as the *Ammophila arenaria* and *Elymus arenarius*, are useful in binding the loose sand of the seashore. Ergot is the ovary of rye attacked by a fungus called *Oidium abortifacens*. The flinty surface of the stems or straw renders many valuable for domestic use, as for forming the *plait* from which straw bonnets, &c. are manufactured. The systematical arrangement of grasses is a difficult and unsatisfactory task, and has occupied the attention of many botanists. Sinclair's *Hortus Gramineus Woburnensis* will, however, be found a useful account of the relative qualities of pasture grasses.

Grammar (Gr. *γραμματική*, sc. *τέχνη*, the *grammatical art*; from *γράφω*, I write). The science which has for its object the laws which regulate human language. Language, in its widest acceptation, may be defined to be the expression, by means of outward signs, of what passes in the mind. If, therefore, it is to admit of rules, or general laws, it is plain that we must seek those laws either in the constitution of the mind where it originates, or of the outward materials of which it is composed. These are either sounds, visible images (i.e. letters as representing sounds), or gestures. Grammar takes account of the first two only. [GESTURE LANGUAGE.] The material of language, when it is sound, is capable of analysis into a definite number of simple elements. It is not our object at present to enter on the consideration of this part of language, whether consisting of sound, or marks to designate sound. We pass on to its more important class of laws, which result from the internal conditions of the mind; and which, viewed in that reference, constitute the subject-matter of philosophical grammar, properly so called. An analysis of our mental faculties must therefore precede any attempt to define the province and settle the principles of grammar. Of the various divisions of the human faculties proposed by philosophers, we shall adopt, as best suited to our purposes, that which distinguishes them into two grand classes — the province of affection, and that of perception or intellection. The discriminating mark of the former class, under which we include alike the outward senses and the inner sense or emotion, is this, that the faculties which it includes imply a state of mind or consciousness, and that only. By perception or intellection, on the other hand, are meant those states of mind which refer to a real or supposed object, out of the mind itself. 'To know' and 'to know nothing' are contradictory conceptions; every act of knowledge implies at once an object and a mind to which that object is present. Each of these portions of the mind has its appropriate expression, its peculiar language. The language of emotion is common to men and animals. It consists, for the most part, of certain simple sounds or exclamations, which, if capable of being reduced to rules at all, must rest for those rules on physiological considerations, which form the province of philosophical grammar. We must seek that province, consequently, in the language of intelligence or reason. Rational discourse, or human language, may be figuratively expressed as the outward type or form which thoughts, and the laws which regulate them, impress on the material of sound. In the words of Plato, 'reason and discourse are one; only the former, as the conversation of the soul with herself, which goes on without the intervention of sound, has obtained among us the name of discourse of reason.' We do not deny that language, in this limited sense, may become the expression of emotion in ourselves, and excite emotion in others. Both these objects,

GRAMMAR

however, it can effect only *mediately*: the first, by converting, through reflection, an emotion into an object of consciousness; by rendering it *intelligible* to ourselves, then *intelligible* to others: the second, only *through* the understanding of those whom we address. The laws of language must therefore correspond with the laws of the intellect: if there is anything universal and necessary in the one, its representative or image must be found repeated in the other. But the necessary laws of thought are the object-matter of logic. It might, therefore, seem that logic and universal grammar are convertible terms. Both sciences consider alike the forms of the intellect, and the right mode of expressing these forms in language. But they differ in this, that logic considers the intellectual process primarily, and its expression in language only incidentally; whereas grammar considers the former only in so far as it conduces to the right understanding and due regulation of the latter. Having previously distinguished philosophical from merely practical or empirical grammar, we may now distinguish philosophical grammar itself into universal and particular. The first, as we have seen, corresponds to logic: as the one is the science of those conditions which must be presupposed in order to render *thought* and *intelligence* possible; so the other contemplates the conditions which are to render possible the *outward expression* of thought and intelligence. The same relation which universal grammar bears to logic, particular grammar, philosophically treated, may be said to hold to the kindred science of psychology. It considers the experimental laws of the mind with the same view with which universal grammar contemplates those that are necessary. It takes into account the effects of accidental association, in order to explain the idioms or peculiarities of the particular language before it. It calculates, so to speak, the disturbing forces which act on the general law.

In developing the principles of universal grammar, we shall consider, in order, the various kinds of words or *parts of speech* into which language is ordinarily distinguished.

The first class of words corresponds to the faculty called by logicians *apprehension*, or simple apprehension. They are commonly named *nouns*, or *substantives*, or *nouns substantive*; and express either individuals, as 'John, Charles'; or classes, as 'man, animal.' They are called *substantives* because they express a real or supposed substance, a something which is conceived to stand under, or, in scholastic language, to be the support of, certain qualities. These qualities may in their turn be considered as substances, and expressed by substantives, as *whiteness, greenness*. When considered in relation to the substance of which they are properties, they constitute the second class of words—*adjectives*, or *nouns adjective*. Thus we say, 'a white horse, a dazzling whiteness,' where the same conception which in the former case is regarded as a quality, and expressed by an

adjective, is in the second converted into a substance, itself the *support* of other properties.

Thus far the only intellectual power implied in language is that of forming general conceptions. A conception, when formed, is capable of being resolved back into its constituent parts. In the conception 'stag' we find the property of swiftness contained. This *attribution* of a quality to a substance, is what logicians call a *judgment*; its expression in language is an affirmation, or proposition. The *sign* of this attribution is called the *copula*: 'The stag is swift.' Every judgment which has regard to matter of fact considers an event either as past, present, or future: 'The hair *was* light, *is* dark, *will be* grey.' When the attribute property or quality is combined with the copula or word signifying the affirmation or attribution, a third class of words is produced, to which we give the name of *verbs*. Thus instead of saying, 'the sun *is* bright,' we may say, 'the sun *shines*,' where the latter form of expression is equivalent to, or capable of being analysed into, the former. A *verb* is therefore a compound part of speech, consisting of an adjective and a *copula* or *affirmation*, and signifying not only the conception of a *property*, but our perception or judgment that such property does inhere or belong to some substance, or else that it *has* belonged or *will* belong to it. The relation between property and substance, expressed in every proposition, may be differently stated as the relation of part to whole, of species to genus, of individual to species; distinctions which do not concern us at present, inasmuch as grammar, no less than logic, has regard only to our mode of conceiving things, not to things as they are in themselves.

The three parts of speech which we have thus analysed—the substantive, the adjective, and the verb—are called the *primary* or *essential* parts of speech. They are those without which no discourse could take place, no act of judgment be communicated; in other words, without which no sounds could have *meaning*. The parts of speech which remain to be considered are the *pronoun*, the *article*, the *adverb*, the *preposition*, the *conjunction*, the *interjection*.

The *pronoun* is so called from its being a substitute for a noun; a compendious contrivance to avoid repetition, or needless and inconvenient specification: as, 'John is tall and *he* is handsome,' which is equivalent to saying, 'John is tall and *John* is handsome.' They are commonly subdivided into personal or substantive, adjective, demonstrative, relative, indefinite, and interrogative pronouns.

Articles are words joined to substantives, for the purpose of defining whether the substance or conception is to be understood in a general sense, or in particular relation to an individual. When the first is our intention, we use in English no article whatever: as, '*Man* is corrupt;' by which we mean that corruption is an attribute of the genus 'man,' and not of any particular individual to the exclusion of others. If we used the article *a* or *an*, we should in

GRAMMAR

most instances mean that some individual or other of the species was contemplated: 'I saw a horse.' When we use the definite article *the*, we mean to specify which individual of the species we have in view.

The *adverb* derives its existence from the difficulty of defining by one word the precise quality of a particular object. When we say a thing is 'green,' we may call up in the minds of our hearers the image of a very different shade of greenness from that which we are describing. If we say it is 'very green,' our language is more definite. An *adverb* may consequently be described as a *modifying* part of speech, joined with adjectives or verbs to define more accurately the degree of the quality or circumstances of the action predicated. That it is not an essential part of language is evident from the circumstance that its place may be supplied either by a termination, as 'greenish,' for 'rather green;' or by a periphrasis, as 'he walks with speed,' instead of 'he walks rapidly.'

Prepositions are those parts of speech which express relations between substances, and are consequently joined only with substantives; as, 'from the city to the country.' We shall consider them more at length when we come to treat of the inflections of words.

As prepositions express objective relations, so *conjunctions* may be said to represent those of a subjective nature; or those relations which we perceive to exist between the judgments of our own intellect, whether of mere succession, of inference, or the like. They are consequently used to connect propositions together; as, 'John is wise, therefore he is good;' 'John is wise because he is good,' &c. They are to the syllogistic faculty, or the faculty which perceives the connection and dependence of simple judgments, what the *copula* is to the faculty which forms these judgments. As the one forms words into propositions, so the other are necessary to combine propositions into sentences.

The *interjection* is the expression of emotions, and emotions only. It is not, therefore, confined to human discourse; and as it has nothing to do with the operations of the intellect, is incapable of logical combination with other words. It might therefore be doubted whether it can with propriety be called a part of speech at all.

We have said that the last-mentioned 'parts of speech' were not necessary constituents of language. We so far qualify that assertion, in regard to prepositions in particular, as to admit that they are the expressions and modes of conception which the human understanding unavoidably forms. Whether, in technical language, the necessity be a *formal* or a *material* necessity, we forbear to discuss at large; since it is a subject on which logicians are not agreed. We ourselves are inclined, with Kant, to think it *formal*. We conceive the relations of cause and effect, of time and place, of action and passion, to be as much pure educt of the understanding, and as independent

for their *form* on experience, as those of *part* and *whole*, *substance* and *attribute*, which we have seen to constitute the necessity for the primary parts of speech. They differ, however, in this, that the latter *must* enter into every proposition to render it a proposition at all; while those which we are now considering may or may not, according to the matter in hand. In all languages they are expressed more or less perfectly. In our own, and in the other branches of the Teutonic stock, this expression is effected in two ways. Either the relation intended to be implied is expressed by an affix or prefix to the radical or abstract portion of the word itself; or the relation is regarded as abstracted from all particular objects between which it might be conceived to subsist, and, so abstracted, is embodied in a distinct word or particle. Thus what the Latins expressed by the termination *o* or *i*, as 'domino,' 'nubi,' is represented in English by the prepositions 'to' or 'for.' Generally speaking, the earlier a language, the richer it is found to be in terminations; which, as the faculty of abstraction becomes habitual, are commonly abridged in number, and replaced by particles. A word which admits a variety of such modifications is said to be *declinable*. The only *declinable* or *inflected* parts of speech are the substantive and the verb, and in some languages the adjective and participle, with the representative parts of speech, the pronoun and article. The reason of this is sufficiently obvious. It is between supposed substances that the relations of cause and effect and those of place are conceived to exist; while the relations of time pertain to action and passion, or those changes in the state of substances which are expressed in language by verbs. The declension of adjectives is an anomaly in language. It probably results from the facility with which we convert in our thoughts a quality or attribute into a substance; unless it is to be accounted for by what grammarians call 'attraction;' a supposed influence which the inflexion of a word exerts over those immediately in contact with it, and which is owing partly perhaps to the desire of euphony, and partly to a confusion of thought, the effect of association. The sum total of the modifications which the words of a language admit constitute what is called the *accidence* of that language. The circumstances under which such modifications or inflexions take place are the subject-matter of that part of grammar which is named *syntax*. These inflexions are, in *nouns*, case, number, and gender; in *verbs*, tense, mood, person, and, in most languages, number.

The *cases* of nouns are the expression of the relations of substances. In Latin there are, besides the nominative, or absolute form of a conception, and the vocative, used in addressing or calling to another person (a compound of a noun and an interjection), four cases properly so called; the genitive, the dative, the accusative, and the ablative. Of these the Accusative language retains in its nouns one only, the genitive; in its pronouns two, the genitive and

GRAMMAR

accusative. All other cases it replaces by prepositions.

The genitive case expresses the relation of *property*. A single conception is capable of being analysed into a number of constituent parts, which are either necessary to the whole conception, or bound up with it by association more or less habitual. We represent this process in language by some change either in the word which signifies the *property*, or in that which denotes the containing substance. The last is the case in most European languages. Thus, we speak in Latin of *color equi*, the colour of a horse; *philosophia Socratis*, the philosophy of Socrates. For the controversy respecting the genitive case in English, see the *Inquiry into the Character and Origin of the Possessive Augment*, by Serjeant Manning.

The dative case implies *participation* in the effect of an action, expressed in English by the preposition 'to' or 'for.' 'Dedi ei,' 'I gave it to him;' where the effect of my act of giving is *shared only* by another.

The accusative is used where the effect of an action is conceived as passing over *entire* to another substance: 'Laceravi librum,' 'I tore the book;' where the whole of the immediate effect is conceived as confined to the book which I tear. It is also called the *objective case*.

The ablative case, if we regard its etymology only, we should define to be that which expresses loss or privation. In this sense it ought to be considered as a modification of the dative, or the case which expresses the incidental or participated effects of an action; and we accordingly find that in Latin the English preposition 'from' is frequently expressed by the dative. There is, however, a kind of relation which no other case serves precisely to convey, that of outward proximity, which is expressed in English by such prepositions as *at*, *near*, *by*, *upon*, and in Latin by the ablative case, which consequently is not so useless or superfluous a form as some grammarians have considered it to be. It must, however, be remembered that this system of cases is in some measure the arbitrary work of Greek and Latin grammarians, and that great confusion and difficulty has been caused by treating as a single case what are really several cases, although alike in form. [LOCATIVE CASE.]

Besides the inflexion of case, nouns admit, in most languages, those of number and gender. The latter is a mere generalisation from experience; and though it may be convenient to have a termination to designate it, it is not necessary, as is apparent from our own language, which expresses this distinction only in its pronouns, and in some few of its substantives. Our conceptions of number are doubtless conditions of our mental constitution. They may be generalised under the forms of unity simple, unity comprehensive, and plurality. Unity, whether regarded simply or as an aggregate, is expressed by the singular number. Many languages, besides singular and plural,

have a form to denote duality, or *two things together*; a fact which, probably, is owing to the duality of the parts of the human body, as the hands, feet, &c.

We proceed to consider the different kinds of *verbs*, and their modifications. Verbs are divided into transitive, intransitive, and passive. They admit necessarily of time and mood; accidentally and by usage, of *person* and *number*.

A property, taking the word in the most general sense of which it is capable, may be conceived either as a state, a process, or as a power in action. To the first two correspond the verbs commonly called intransitive, or neuter, as 'I rest,' 'I grow,' 'I fall.' When a power is in action, we measure it by its effects on some substance; we conceive the action as *passing on* to another object, as 'the clouds bring rain.' The verb which expresses this transition is called the *verb active* or *transitive*. But not only are we able to conceive an object exerting power; we may also consider it as susceptible of influence or change from the action of another object. This is expressed by the verb passive, as 'the dog was beaten.' Many other modifications of action and change have their appropriate forms in different languages. Such are the verb middle or reflex in Greek, the verbs frequentative and desiderative in Greek and Latin. These, however, are matters of idiom, not of universal necessity.

Equally extensive with the conceptions of cause and effect is that of time, as the universal condition of all change in nature. The words which signify the one must therefore be capable of expressing the other. Hence the necessity for *tenses* in verbs, or the inflexions which determine the time of the action, as present, past, or future. We may further abstract an action from its relation to time altogether; and this abstraction is in some languages, as in the Greek, represented by a form appropriate to the purpose, called the *aorist*. [AORIST.]

The modifications of verbs which we have been considering concern change or action objectively, or in relation to the substances which they are supposed to affect. Our judgments themselves are also liable to certain modifications, which, as regarding only the way in which we conceive of events, may be said to constitute the subjunctive conditions of verbs. Our knowledge of an occurrence may be either certain or uncertain; and uncertain either absolutely, or only under particular suppositions. When we simply express our judgment that a thing is, has been, or will be, in such and such a state, we are said to speak indicatively, or in the *indicative mood*. When we consider a thing as possible merely, we use the *potential mood*, denoted in English by the auxiliary verbs 'may' or 'might.' When we speak of it as dependent for its occurrence on certain conditions, or in case of its occurrence as connected with certain probable or inevitable consequences, we use the *conjunctive mood*: 'I would go, if he would let me.' Different languages express these modifications of judgment more

or less perfectly; none, perhaps, with absolute accuracy.

Two other modal forms still remain to be considered. They have been called by grammarians the *imperative* and *optative moods*, as conveying the expression of a command or a wish. They may be included under the general term of *desiderative*, and imply at once the conception of an event and our desire that that event should take place. They may therefore be regarded as forming the connecting link between verbs and interjections; between the words which belong to the perceptive and those which pertain to the emotive part of our nature.

What is commonly named the *infinitive mood* may be considered as the point of transition from a verb to a substantive. It is, so to speak, a *substantised attribute*, and is used as the subject of a proposition as correctly as substantives themselves: e.g. '*To die* is gain.'

The *participle* is usually ranked as a separate part of speech. It may be said to hold the same intermediate place between a verb and an adjective, as the infinitive holds between a verb and a substantive. It possesses all the properties of the verb, save affirmation; that is to say, to the properties of the adjective it adds the power of denoting time.

The attribution to verbs of number and person is logically as anomalous as it is to assign gender and number to adjectives. Most languages fall into this error, which is, however, susceptible of a very easy historical solution. It arose, doubtless, from the original custom of annexing the pronoun to the termination of the verb, and continuing the use of the inflection after its import had been forgotten, and when the pronoun had been formed into an independent part of speech.

GRAMMAR, COMPARATIVE.—Although languages can be classified only according to the character of their grammatical forms, yet the principles by which these forms are developed run through all languages, in so far as they may be said to possess any grammatical system at all. Differences of grammar mark off the families of human speech by barriers which are never overpassed. A language may borrow from the vocabulary of another language, until, like the Araucan of America, it has more foreign than native words in its dictionary; but its grammar never changes. There can be no such thing as a mixed language, if by this term we refer to its grammar, and not merely to the words which it has moulded into its own shape. But vast though the differences of grammatical forms may be between one language and another, the same process of formation may be discerned in systems at first sight utterly opposed to each other. Thus the termination *-ing*, in such phrases as *I am going*, is proved to belong, not to the present participle, but to the locative case of a verbal substantive. The same result is obtained by examining the so-called present participles in French, which the French Academy decreed in 1679 should no longer be declined. This decree, in fact,

merely affirmed that such words were not participles at all, but the oblique case of a verbal noun. The Bengali exhibits the same process, the so-called infinitive being formed by *-te*, which is also the termination of the locative singular; and hence *karitechí, I am doing*, answers exactly to the old English idiom, *I am on doing*. Languages not belonging to the Aryan family show the operation of the same principle. In the Basque, the locative is formed by the suffix *an*. This suffix appears again in the present indicative, so that *erorten nix, I fall*, is literally, '*I am a-falling, or in the act of falling.*' [FUTURE TENSE.] Other instances of the same kind may be found in Professor Max Müller's *Lectures on Language*, second series, p. 30, &c.; the conclusion forced upon us by all being that though the materials are different, the system is throughout the same. The disposition of these materials furnishes the real criteria of classification, which will be examined more at length in the article LANGUAGE. The reduction of languages into families and groups by the analysis of their system of construction is the office of comparative grammar.

Grammarians. Literally, one versed in grammar; but the term was used by the classic ancients as a title of honourable distinction for all who were considered learned in any art or faculty whatever. (Vossius's work on Grammar.)

Grammatite. The name originally given by Haiu to the mineral usually called *Actinolite* or *Amphibole*.

Gramme. The French integer of weight = 15.432 English grains. [WEIGHTS.]

Grammite. A mineralogical synonym of the variety of bisilicate of lime, commonly called *Tabular spar* or *Wollastonite*.

Grampus (a catachrestic form of the Fr. *grand poisson, large fish*). The *Delphinus orca*, or thresher, a large species of Arctic dolphin, which is frequently found on our northern coasts.

Granade. [GRENADE.]

Grand Jury. [JURY.]

Grand Serjeanty. [FEUDAL SYSTEM.]

Grandee (Span. *grande de España*). The highest title of Spanish nobility. The collective body of the higher nobility in Spain is termed *la grandeeza*. They were originally the same with the *ricos hombres*. Grandees bear different titles—duke, marquis, &c.; but there is no essential difference of rank between these titles: all are equal among themselves. Grandeeships descend through females, and thus become accumulated in families.

Grange (Fr.; Ital. *grangia*, from Lat. *granum*). A farmyard or farmery, which consists of a farmhouse and a court of offices for the different animals and implements used in farming, and also of barns, feeding houses, poultry houses, &c. [FARMERY.]

Granite (Ital. *granito*, as formed of *grains*). The name popularly given to a large group of rocks consisting of crystals, generally of felspar and mica or some allied minerals, embedded in quartz. Crystals of quartz, mica, hornblende,

GRANITE

or talc embedded in felspar would have the same general name.

Great confusion has arisen in geology from the indefinite use of this term. Rocks of different ages, in different geological positions, have been considered identical; and all the older crystalline rocks, besides some of the newer ones, have often been described under the same name.

It has been a question whether granite is strictly an eruptive rock that has once existed in a fluid state. There appear to be many cases in which this is proved by experiment and observation. On the whole it seems probable that it is a rock, formed at great depth and under enormous pressure, consisting of many ingredients, and sometimes even containing water; and that it has often been pressed into veins and narrow fissures, where it has crystallised.

Most granites are hard, compact, and durable, and often mark the central axis of a mountain chain. There are, however, some varieties, which decay with comparative rapidity. De Luc talks of the *friable granite* of the Harz, and Saussure describes the mouldering down of that of the Alps. The waters of the Arve are rendered turbid by the pulverulent felspar that comes from the Aiguilles de Chamouny and other points that border the Mer de Glace. The road across Dartmoor from Ashburton to Chagford traverses, in one place, such loosely compacted granite as to resemble a bed of gravel. The granite of the Carglaise mine, near St. Austel, is so soft and pulverulent, that the excavation might almost be taken for a chalk pit; and near that mine there are immense quantities of white porcelain earth, or *kaolin*, of similar origin, due to the perishable nature of the felspar, which, giving way, suffers the grains of quartz and mica to fall out. Chemical analysis points to the loss of the alkali of the felspar as the cause of this extreme proneness of some kinds of granite to decay. Independent, however, of chemical composition, the mechanical texture influences their relative durabilities. When the arrangement of granite resembles that prevalent in the greater part of Cornwall, water gradually penetrating between the blocks and into the natural joints of the stone freezes there, and thus slowly removes the granite into gravel. The more solid texture of other varieties of granite prevents the decay referable to that powerful cause.

Under the term *granite formation* are sometimes included not merely granite properly so called (which is a crystalline aggregate of quartz, felspar, and mica), but the other rocks into which it merges, either from the predominance of one or other of its ingredients, from the loss of one or other of them, or from the occasional addition of some new mineral. These will be described in various articles, each under the name most generally given to it.

The largest granite tract of England is that of Devon and Cornwall, where its sides are covered by slate, but where it rises in several

GRAPE SHOT

places to the surface; it also forms the rocky promontory of the Land's End. Dartmoor forms a large mountain tract of nearly 80,000 acres in extent, strewed with boulders and fragments, which appear to set cultivation at defiance. The highest point of this district, near Okehampton, is 2,070 feet.

Granite is widely spread, and many large tracts are entirely made up of it. Where it decomposes readily, it passes into a good soil, not naturally rich, but capable of becoming so by the addition of organic matter. In other places it rises into lofty and picturesque peaks of mountain, forming the most magnificent scenery in the world.

Granivoræ (Lat. *granum*, a grain; *voro*, I eat). The name given by Temminck to an order of birds, including the Inseosorial species which feed on grains: other animals with a similar diet are termed *granivorous*.

Grant (perhaps another form of *warrant*, *guarantee*, &c.: Mr. Wedgwood, *Eng. Etym.* s. v. connects the word with Lat. *gratus* and *credentia*). In Law, a mode of conveyance by deed, now the common method of transferring land, and all other descriptions of real property of freehold tenure (stat. 8 & 9 Vict. c. 106).

Granulation. The method of dividing substances into grains or drops. With the metals it is usually effected by pouring the melted metal into water; if fine division is required, it must pass through a perforated ladle or sieve; and in order to obtain spherical particles, it must fall from such a height as to become solid before it meets with the water; hence the height of the towers in which *shot* is made. Another form of granulation is that practised upon certain pasty substances, as seen in the *globules* of the homœopaths, and in some effervescent remedies which in consequence of their granulated form are more slowly acted upon by water than when in fine powder, so as to render the effervescence more gradual.

Granulations. This term is applied to the little granular formations which arise in sores that are healing, and by which the destroyed parts are filled up and the edges brought together. When healthy, they are of a red colour, not exuberant; when unhealthy, they are pallid, and become soft, spongy, and irregular.

Grape (Ital. *grappo*, as growing in bunches or *handfuls*). The fruit of the Vine, *Vitis vinifera*. Grapes are useful not only in the fresh state as one of the foremost of dessert fruits, and in the dried state as raisins [CURRANT], but as furnishing the material for the manufacture of wine. [WINE.]

Grape Disease. [OÏDIUM.]

Grape Shot. In Artillery, consists of a number of cast-iron balls, arranged in three tiers by means of circular plates, the whole secured by a pin which passes through the centre. The number of shot in each tier varies from three to five. It is very destructive up to 300 yards, and effective up to 600 yards but not farther.

GRAPE SUGAR

Grape Sugar or Glucose ($C_{12}H_{22}O_{11}$, or $C_{12}H_{22}O_{11} + 2HO$). This modification of sugar abounds in grapes, figs, plums, and other fruits: it is also the result of the action of *diastase*, and of dilute acids upon starch. In good seasons the expressed juice of grapes yields from thirty to forty per cent. of solid matter, the greater part of which is this kind of sugar. When obtained from fruits, it is generally accompanied by more or less of an uncrystallisable sugar, called *Fruit-sugar* or *Fructose* ($C_{12}H_{22}O_{11}$), which, by assimilating the elements of water, passes into the condition of glucose. The conversion of starch into this kind of sugar is a process extensively carried on as a commercial manufacture. Potato-starch and sago are principally used: they are saccharised by the action of dilute sulphuric acid (10 parts of acid to 1,000 of water and 500 of starch). The dilute acid is heated by steam, and the starch, previously mixed with water of a temperature between 112° and 130° , is suffered gradually to dribble in under constant stirring; in about two hours and a half the whole of the starch is added, and in from fifteen to twenty-five minutes afterwards the saccharification is complete; the steam is then shut off, and the liquor transferred to another vat, in which the acid is saturated with chalk. When the sulphate of lime has subsided, the clear liquid is drawn off and evaporated to the specific gravity of about 1.26. The resulting syrup is then left to deposit the sulphate of lime separated during evaporation, and afterwards drawn off perfectly clear. In this state it may be used as a source of alcohol, or for sweetening coloured liquors; but it requires, for some purposes, to be deprived of colour, which is done by filtering it through animal charcoal. When required in its solid state, the syrup is evaporated in a steam vat till of a specific gravity of about 1.4, and then poured into coolers, where it concretes.

Glucose differs from sucrose, or cane-sugar, in being less soluble in water, and more soluble in alcohol, so that the two may be to some extent separated by the action of alcohol. The sweetening power of glucose is also greatly inferior to that of sucrose, 2 parts of the latter being in this respect equivalent to about 5 of the former. Sucrose easily crystallises in prisms, but glucose forms tubercular concretions, or fibrous acicular groups, = $C_{12}H_{22}O_{11}$, $2HO$. Both these sugars form definite crystallisable compounds with chloride of sodium.

Graphic Acid. A yellow crystalline body, resulting from the continued action of sulphuric acid and chlorate of potash on graphite.

Graphic Gold, Graphic Tellurium (Gr. γράφω, *I write*). Mineralogical synonyms for Sylvanite, having reference to the particular appearance produced by the aggregation of the capillary crystals, which are frequently arranged in rows more or less like graphic delineations.

Graphite. This substance, under the name of *Black Lead* and *Plumbago*, is well known in the manufacture of pencils, for which purpose

GRAPNEL

it was chiefly obtained from the mine of Borodale, at the west end of Derwent Lake in Cumberland, where it was first wrought during the reign of Elizabeth; but this locality is now nearly worked out. It has lately been found in enormous masses in North-eastern Siberia. In a less pure state, it is not an uncommon mineral, occurring in detached masses, generally in primary rocks. It is thus found in Germany, France, India, Ceylon, and North and South America. It is of an iron-grey colour, metallic lustre, and soft and greasy to the touch, producing a leaden mark on paper. Its specific gravity varies from 1.9 to 2.5: it occasionally occurs crystallised in hexagonal plates; it conducts electricity, and for this purpose is much used in the electrolytic process. It is infusible, very difficult of combustion, and when mixed with fire-clay is a useful ingredient in the manufacture of crucibles and melting-pots intended to withstand high temperatures. It undergoes no change in air, and is used to cover articles of iron to prevent rust, and also for lubricating machinery. When burnt in a stream of oxygen gas, it leaves a residue of yellow ash, composed chiefly of oxide of iron, with silica and titanate acid, but varying in quantity in different specimens. In good plumbago, the carbon amounts to 96 per cent. The oxide of iron is an incidental ingredient, and is not in chemical combination with carbon. Broekedon found that the dust of plumbago might be forced, under great pressure (like spongy platinum), into a coherent mass, which might be cut and applied to the same uses as the native substance; and Brodie has patented a process for the purification of ordinary graphite. Some kinds of cast iron, after long immersion in sea-water, leave a substance which has some of the characters of graphite.

Graphotype. A recently discovered mode of producing engravings for working as woodcuts by letterpress, the principal value of which is that it needs no engraver to interpret the work of the artist. It is said that the cost of graphotypes is about one-tenth that of wood engravings. The process is thus described: A layer of prepared chalk is compressed by hydraulic pressure upon a plate until the surface of the chalk is as smooth as a sheet of paper. The artist draws on this surface with an ink which has the property of making the chalk which it touches harder than the remaining surface. A soft brush or a piece of velvet is now rubbed over the plate, from which it removes part of the untouched chalk, leaving the inky portion in relief. When these lines are considered deep enough, the whole plate is saturated with a chemical solution, which hardens the chalk. From this, impressions may be taken direct, or stereotypes or electrotypes may be obtained as soon as the stone is dry. Some graphotypes are said to rival in beauty and delicacy the best engravings.

Grapple. A small anchor of several claws, used in mooring boats and small craft: also employed in close action between ships for the purpose of seizing the rigging of the adversary.

GRAPTOLITIDÆ

Graptolitidæ (Gr. *γράφω*, *I write*, and *λίθος*, *stone*). These fossil bodies, which have been found throughout the Silurian deposits, have been placed provisionally in the class *Polypi*. The axis of the polypary is sometimes straight, sometimes spiral, and serrated either on one or two sides. They occur in argillaceous strata, and it has been conjectured on good grounds that they presented a more generalised structure, nearer to the ideal type of *Polyp*, than the specially differentiated *Sertularians* and *Pennatulidæ* of the present day.

Grass Land. In Agriculture, land kept perpetually under grass, as contrasted with land which is alternately under grass and tillage. Perpetual grass lands are generally such as from the soil and situation are too moist to be ploughed with advantage, or too hilly and irregular on the surface to be ploughed at all. Hence we have hill pastures, and low moist meadows. The former admit of very little improvement, excepting that of drainage, and occasionally, in low hills, of irrigation; while the latter may not only be drained, but may be manured, and in some cases irrigated. [**PASTURE; MEADOW; IRRIGATION.**]

Grass-oil. Some of the *Grasses* yield odorous volatile oils, as the *Anthoxanthum odoratum*. The *Andropogon citratus* yields the oil of *lemon-grass*, much used in perfumery under the name *oil of verbena*; and the *grass-oil of Namur* is distilled from the *Andropogon calamus aromaticus* or *nardoides*.

Grasshopper. [**LOCUST.**]

Grauwacke. A name given by the German geologists to a peculiar variety of fissile sandstone, consisting of small fragments of quartz, flinty slate, and clay slate, all cemented into a kind of stone by argillaceous matter. Occurring only in a fixed geological position in Germany, or at least being abundant in that position, it was long regarded as an important rock among those assumed not to contain fossils. Like other mechanical rocks, it has no necessary limit of age, if regarded as a mineral type. Most of the deposits so called have since been found to contain fossils, and belong to all periods. [**WACKE.**]

Grave. In Music. [**ALLEGRO.**]

Gravel (Ital. *gravella*, Fr. *gravelle*). This name is generally given to any accumulation of rounded pebbles with sand. Almost all matters so called are of tertiary origin; but gravels may exist of any geological period. All the best gravels of England were formed and deposited during that period when the country was covered by glaciers or swept over by icebergs, and thus gravel and *glacial drifts* are almost synonymous. [**GLACIAL DRIFTS.**]

Gravel is distributed in patches over England, and often in thick beds, having some appearance of stratification, and containing animal remains. Among these, human remains have been found in France and parts of England, showing that human beings must have overspread Western Europe when the land was in a very different form, and when its quadru-

GRAVING DOCK

pedal inhabitants included elephants and rhinoceroses. [**FLINT IMPLEMENTS.**]

Large quantities of pebble beds used as gravel, occur in the lower tertiary deposits of England. Where true gravel does not exist, decomposed granite is often known by the same name, but it is a poor substitute. Even broken shells are often used near the seaside for some of the purposes of gravel.

GRAVEL. In Gardening, gravel is an important article, being that of which walks are formed wherever it can be procured. In selecting gravel, two qualities are chiefly to be sought for; viz. a good colour, and the property of binding. The most common colour of pit gravel is a rusty brown; and that of river or sea gravel, a grey, with different shades of white, red, or brown. The best colour is a deep rich yellow, which is that of the gravel of Kensington, the stony parts of which are flints. The binding properties of gravel depend upon the presence of ferruginous clay, and the irregular and angular shapes and sizes of the stones. Where the stones are round or oval, with regular smooth surfaces, they never form a good binding gravel.

Gravel, Urinary. [**CALCULUS and URINE.**]

Graver, called also **Burin**. A sharp tool, with a triangular extremity, for cutting the lines of an engraving on the copper. [**ENGRAVING.**]

Graves or **Greaves**. The sediment of melted tallow, composed of the membranous, vascular, nervous, and muscular matters blended with the fat, and which, not being fusible, are easily separated from it by straining; they are made up into cakes, and sold by the tallow-chandlers, being chiefly used as a coarse food for large house-dogs.

Gravimeter (Lat. *gravis*, *heavy*, and Gr. *μέτρον*, *measure*). An instrument for ascertaining the specific gravities of bodies, whether liquid or solid. The particular instrument to which the term is usually appropriated was invented by M. Guyton, who adopted this name in preference to *areometer* or *hydrometer*, because the latter terms imply that the liquid is the thing weighed; whereas, when solids are weighed, the liquid is only the term of comparison to which the unknown weight is referred. [**HYDROMETER.**]

Graving Dock. A name given, in Hydraulic Engineering, to an enclosure made on the side of a river, or of the seashore, into which a vessel can be floated for examination and repairs. There are generally several graving docks attached to naval arsenals; and they are also in use for the mercantile navy, at Liverpool, London, Glasgow, Bristol, Hull, Havre, Marseilles, &c. A graving dock in general consists of the *lock* at the entrance, which may be closed either with gates or a pontoon; the *altars*, as the steps at the side are called, and the *floor*; the *pumping-engine*, and the *tar-melting place*. The dimensions given to graving docks at Woolwich are 265 feet in length, from the apex of the semicircular and

GRAVITATION

to the inside of the gate; the width at top 80 feet, at bottom 37 feet; the clear width of the entrance 65 feet; the height from the quay line to the upper side of the invert, 26 feet. The sides are, in this case, made in steps varying from 9 in. to 16 in. in height, and from 9 to 16 in. wide, excepting the broad altar, which is 18 in. wide. There are two staircases for the men at the entrance; one slip for lowering the materials at the head, and one on each side of the dock; the walls are, in this case, 4 feet thick at the top, and 25 feet 6 inches at the bottom.

Of late, the authorities of some ports, as Havre, Carthage, &c., have introduced a system of floating dock, instead of building a graving dock in the dry ground. These docks consist of a framework, in every respect analogous to the interior of the latter, which is sunk near the ship, and then raised by the pumping out of the water in which the ship floated. These can be advantageously applied wherever there is a large water surface to be disposed of, but they are not applicable when space is valuable, nor are they so convenient for the approach of materials. Perhaps the most ingenious substitute for the ordinary kind of graving dock is Clark's **HYDROSTATIC DOCK**, in which the ship is fastened on a platform sunk beneath its keel, and then the whole of the platform, ship and all, is raised out of the water by hydrostatic pressure, made to act upon pillars connected with the platform by suspension rods.

Gravitation, Gravity (Lat. *gravis*, heavy). These terms are often used synonymously to denote that mutual tendency which all bodies in nature have to approach each other, with forces which are directly as their masses and inversely proportional to the squares of their distances.

That every particle of matter in the universe has a disposition to press towards, and, if not opposed, to approach to every other, is a fact of which we derive the knowledge partly from our constant experience of what takes place at the earth's surface, and partly by reasoning from the observed motions of the celestial bodies. This mutual tendency of all the particles of matter to each other is called the *attraction of gravitation*. In reference to any particular body, or mass of matter, the aggregate attraction of all its particles is usually called simply its *gravity*.

Gravity, Terrestrial.—Universal experience demonstrates that all heavy bodies, when unsupported, fall towards the surface of the earth. The direction of their motion may be ascertained by a plumb-line; and it is found to be always perpendicular to the level surface of the earth, that is, to the surface of stagnant water. But the earth is very nearly spherical, and a line perpendicular to the surface of a sphere must pass through its centre; hence the direction of a body moving in consequence of the force of terrestrial gravity is towards the centre of the earth. And this is the direction

in which it must move if the force of gravity is the resultant of the attraction of all the particles of terrestrial matter on the falling body; for it has been demonstrated (by Newton) that a sphere attracts an exterior body in the same manner as if all its matter were condensed into a single point at its centre.

As bodies when left without support fall from all heights to which they may be carried, it may be inferred that gravity acts on them during the whole time of their descent, and is therefore a uniformly accelerating force. This might also be inferred from the fact, which is easily rendered sensible, that bodies which fall from a greater height arrive at the earth with a greater velocity. But Galileo was the first who proved by experiment that the acceleration of falling bodies is uniform, and that the spaces through which they descend are consequently as the squares of the times of descent. Experiments of this kind are attended with some difficulty on account of the resistance of the air. In order to render this resistance insensible, Galileo caused bodies to descend on planes having a small inclination to the horizon, in which case (neglecting the effects of friction) the velocity is diminished in the ratio of the sine of the plane's inclination. By mounting the descending body on wheels, and forming the inclined plane of a hard substance capable of receiving a perfect polish, the friction may also be so much diminished as not to change the nature of the motion. But the best method of showing experimentally that gravity is a uniformly accelerating force is by means of an apparatus called (from its inventor)

Attwood's machine. This consists of a pulley, the axle of which turns on friction rollers, and having a groove on its edge to receive a string. Over the wheel a fine silken cord is stretched, to the ends of which are attached two equal weights, A and B. In this state the weights counterbalance each other, and no motion ensues; but if to one of the weights a small weight *m* be added, the combined weights will immediately begin to descend. The motion which now takes place is exactly of the same kind with that of a body descending freely; but the velocity is diminished in the proportion of the additional weight *m* to the sum of the three, *m*, A, and B; for the force, which is impressed by the additional weight, is expended in giving velocity not only to it, but also to the two weights A and B attached to the string. By this machine the properties of uniformly accelerated motion are experimentally shown to hold true in the descent of falling bodies; for if the additional weight be such as will carry the weight to which it is added through 1 foot in the first second of time, it carries it through 4 feet in 2 seconds, through 9 in 3 seconds, and so on. A proof is therefore afforded by this means that terrestrial gravity is a uniformly accelerating force.

Terrestrial gravity acts equally on all bodies;

GRAVITATION

that is to say, impresses on all of them an equal quantity of motion, whatever their nature may be. This property of gravity was also demonstrated by Galileo. In different hollow spheres, of equal weight and diameter, he enclosed equal weights of different substances: the spheres were suspended by strings of equal length, and made to vibrate in very small arcs, when it was found that the time of an oscillation was the same in all of them. Common experience would seem to be at variance with this result. Light bodies, as feathers, paper, &c., fall slowly and irregularly; and some substances, as smoke, vapours, &c., even ascend. But this, as is well known, arises from the buoyancy of the atmosphere. In the exhausted receiver of an air-pump a piece of gold and a feather fall with the same speed, and strike the bottom at the same time.

Gravity, Terrestrial, Measure of.—Having ascertained the law according to which gravity acts on bodies at the surface of the earth, the next question is to determine its absolute intensity, or the velocity which it communicates to a body falling freely in a given time. On account of the rapidity of the descent of heavy bodies, this cannot be done by direct experiment; nor could Attwood's machine be employed for the purpose with sufficient certainty. The only mode by which an accurate result can be obtained is by measuring the length of a pendulum which makes a given number of oscillations in a given time. Let l be the length of the seconds' pendulum, π the ratio of the circumference to the diameter, and g the accelerating force of gravity, that is twice the space through which a body falls by the action of gravity in the first second of time; then [PENDULUM] we have the equation $g = \pi^2 l$. Now the length of the pendulum vibrating seconds of mean solar time in London, in vacuo, and reduced to the level of the sea, has been determined to be 39.1393 British standard inches; and $\pi = 3.14159$; therefore g is found = 386.3 inches, or 32½ feet. The height, therefore, through which a body would fall in vacuo in a second of time at London is half of this quantity, or 16½ feet. It will be observed, however, that this value of g does not express the whole of the earth's attraction, a small part of which (about the 1-464th) is counteracted by the centrifugal force corresponding to the latitude: it is the force of gravity diminished by the centrifugal force, or what is properly called *gravitation*.

From experiments made with the greatest care, it appears that the extreme amount of the variation of the gravitating force between the equator and the poles is one part in 194 of the whole quantity; that is to say, any body which at the equator weighs 194 pounds, if transported to the pole would weigh 195 pounds. The difference of gravitation, therefore, at the equator and the poles, is expressed by the fraction $\frac{1}{194}$. Now it has been demonstrated by Newton that the ratio of the centrifugal force at the equator to gravitation there is $\frac{1}{289}$. This

is considerably smaller than the fraction $\frac{1}{194}$; but the difference, which is $\frac{1}{589}$, arises from the oblate figure of the earth, in consequence of which a body placed at the pole is at a less distance from the centre than one at the equator, and is therefore attracted more than it would be at the equator, even if the earth stood still, and there was consequently no centrifugal force. From this it may be readily understood that the figure of the earth is determinable by measuring the intensity of gravitation under different latitudes. [DEGREES; EARTH.]

Gravitation, Universal.—Galileo, who had so fully succeeded in exploring the nature of terrestrial gravity, did not suppose that its action extended to bodies beyond the immediate vicinity of the earth. The more speculative genius of Kepler led him to speak of gravity as a force acting mutually from planet to planet, and particularly from the earth to the moon; and he even supposed the tides to be produced by the gravitation of the waters of the sea towards the moon. He did not, however, suppose it to have any concern in the regulation of the celestial motions. Hooke also supposed the heavenly bodies to have a gravitation to each other; but his notions respecting its nature were inaccurate, and he did not attempt to define the law of its variation. This great discovery was reserved for Newton. While meditating on the nature of this force, the thought occurred to him that since gravity is a tendency not confined to bodies on the very surface of the earth, but reaches even to the summits of the loftiest mountains without its intensity or direction suffering any sensible change, may it not reach to a much greater distance, and even to the moon? Before this question, however, could be answered, it was necessary to suppose a law according to which its intensity diminishes. Newton soon perceived that this law would require the force of gravity to diminish exactly as the square of the distance increases; or that the attractive force of the earth at the distance of the moon must be as much less than it is at the surface of the earth, as the square of the radius of the earth is less than the square of the moon's distance from the earth. In a general way, the hypothesis is easily verified. The moon's orbit differs not much from a circle whose radius is equal to 60 times the semi-diameter of the earth, and the circumference of her orbit is therefore about 60 times the circumference of a great circle of the earth. Now the diameter of the earth being nearly 8,000 miles, and the period of the moon's revolution being 27 d. 7 h. 43 m., it is easy to compute that the versed sine of the arc described by the moon in a minute (which is the same as her deflexion from the tangent or straight line which she would describe if there were no force attracting her to the earth) is 16½ feet. But the mean distance of the moon from the earth being 60 times the distance of heavy bodies at its surface from its centre, and her gravity increasing inversely as the square of the distance, her gravity would be 60 × 60 times greater at the surface of the earth than

GRAVITATION

at her present mean distance, and therefore would carry her through $60 \times 60 \times 16.1$ feet in a minute near the surface. But by what was proved by Galileo respecting the descent of heavy bodies, the same force would carry her through 60×60 times less space in a second than in a minute; and therefore the same force which compels the moon to move in her orbit about the earth, supposed to vary according to the inverse square of the distance, would cause her to fall, near the surface of the earth, through 16.1 feet in a second. Now this is exactly the space through which heavy bodies descend in a second; therefore the moon *may* be retained in her orbit by the power of terrestrial gravity.

Newton, however, did not allow the argument for universal gravitation to rest on loose considerations of the lunar orbit as a circle described with an average velocity about the earth. He demonstrated that bodies moving under the influence of an attractive force which diminishes according to the inverse square of the distance must describe conic sections having a focus at the centre of force, and observe the laws of motion which Kepler had discovered to belong to the planetary orbits. He succeeded also in proving that some of the principal inequalities of the lunar and planetary orbits are necessary consequences of the mutual gravitation of the different bodies of the system to each other; and that the same mysterious power not only regulates the motions of all the planets and satellites in space, but also determines the figure of the earth, causes the precession of the equinoxes, and produces the tides of the ocean.

Assuming the different bodies which compose the solar system to be acted upon by their mutual gravitation, according to the law proposed by Newton, namely, that each body attracts every other with a force proportional to its mass directly and to the square of the distance inversely, the determination of the motions of the several planets and satellites becomes a question of pure geometry when the requisite data are determined by observation. If, however, the problem were required to be solved in its most general terms, and it were necessary to consider simultaneously the effects of all the bodies in the system, the difficulties of calculation would be enormous, and in fact no methods of analysis hitherto discovered would be sufficient to grapple with them. Fortunately the actual condition of the system is such as to afford great simplifications. The principal planets are isolated in space, at great distances from each other, and their masses are very small in comparison with the mass of the central body; so that the effects of their mutual attractions are not such as to alter the general elliptic form of their orbits, but merely produce small *perturbations* of their orbits and motions, which admit of being separately computed. By availing themselves of these favourable conditions, mathematicians have succeeded in expressing the whole of the complicated movements of the planets and satellites by analytical equations; and such is the perfection to which this branch

of physical science has attained, that there is no irregularity in the motions of the bodies of the solar system, no deviation from their mean state appreciable to the most delicate astronomical observations, which has not been explained, and its period and amount accurately calculated on the principle of universal gravitation, according to the law discovered by Newton. [PLANET.]

The effects of gravitation, as manifested in the influences of the celestial bodies on each other, enable us to form several conclusions respecting its nature and mode of action. That gravity belongs not only to matter in the aggregate, but to every particle of which bodies are composed, is rendered evident by the manner in which the moon disturbs the waters of the ocean. Let E be the earth, and M the moon. If the moon's gravity acted only on the aggregate mass and not

on each particle, it would have no effect on the figure of the earth, and consequently no tide would be produced. But the action of the moon on the different parts is unequal. Those at *a*, which are nearest the moon, are more attracted than those at the centre *c*; which again are more attracted than the parts at *b*, which are farthest from the moon. The consequence is, that a fluid particle at *a* is drawn away as it were from the general mass, and an accumulation takes place at *a'*. For the same reason, the attraction at *c* being stronger than at *b*, the mass of the earth is drawn away from the parts at *b*, and the fluid is in a manner left behind, and accumulates at *b'*. Hence we perceive the reason why it is high water on opposite sides of the earth at the same instant of time. In fact, in consequence of the moon's attraction, the fluids on the surface of the earth have a tendency at every instant to arrange themselves in the form of an elongated spheroid, the greater axis of which points towards the moon.

It is also proved by astronomical phenomena that gravity is a force which is transmitted from body to body, not successively, but instantaneously. Were gravity transmitted with a measurable velocity, the rate of velocity would sensibly affect the secular variation of the mean motion of the moon. By a comparison of the results of theory with observation, Laplace found that the velocity of the attracting force, if not infinite, must be at least *fifty millions* of times greater than the velocity of light. (*Méc. Céleste*, liv. xvi.)

Another question which may be put with regard to the nature of gravity is, whether its action is in any degree modified by the interposition of the substances through which it penetrates? For example, whether the attractive force of the earth, which must penetrate the whole substance of the moon before its influence reaches the particles on the opposite

side of that body, acts with the same intensity on those particles as on those nearest the earth, regard being had to the law of the distance? Now, if the attractive force suffered any diminution in passing through the lunar substance, the parallax would thereby be affected; but, from the amount of the parallax, it is certain that the intensity of terrestrial gravitation on the different molecules of the moon suffers no variation, excepting what arises from the different distances of the molecules. It may therefore be considered, says Laplace, as sufficiently established that the force of gravity is of so subtle a nature that the densest bodies of the universe offer no obstacle to its free passage.

A third conclusion is, that the law of gravity is not modified in any respect by the different natures of the celestial bodies. If the action of the sun on the molecules of the earth differed only by a millionth part from its action on the molecules of the moon, the difference would occasion a variation of the sun's parallax amounting to several seconds. But the supposition of any such variation is impossible. It follows, therefore, that the gravitating force of the sun, in equal times and at equal distances, impresses equal velocities on the earth and moon. It is also demonstrated from the theory of Jupiter and Saturn, that Jupiter acts on Saturn according to the same law as on his own satellites. Gravity is therefore a force altogether independent of the nature of the substances on which it acts.

Gravity, Centre of. [CENTRE OF GRAVITY.]

Gravity, Specific. The specific gravity of a body is the ratio of its weight to the weight of an equal volume of some other body assumed as a conventional standard. The standard usually adopted for this purpose is pure distilled water at a given temperature. In England the temperature is generally taken at 62° of Fahrenheit's scale; the French take it at 32°, or that of melting ice; sometimes at the temperature at which its density is the greatest (about 39·4° of Fahrenheit). The temperature of 32° is by far the more convenient, inasmuch as it can be easily maintained without variations; whereas it is hardly possible to perform experiments at the exact temperature of 62°, in consequence of the continual variations of the temperature of the air. It is only, however, when very great precision is required, that it is necessary to make the experiment with water at any particular temperature; in general it is sufficient to note the temperature, and apply a correction depending on the known density of water at the different degrees of the thermometric scale.

The most obvious method of ascertaining the *relative weights* or specific gravities of two different bodies is to immerse them successively in a cylindrical or prismatic vessel of a known area, containing a liquid of less density than either. When a solid is immersed in a liquid, the liquid occupies as much more space than it did before as is exactly equal to the bulk or volume of the body; and therefore by im-

mersing equal or known weights of different bodies in a vessel of the form specified, the relation between the heights at which the liquid stands will give the relation between their densities. This was the method proposed by Archimedes for solving the famous problem of the crown of Hero.

The method now employed is susceptible of far greater accuracy. It depends on this principle, that a body when immersed in a fluid loses just as much of its weight as is equal to the weight of an equal volume of the fluid. To obtain the specific gravity of a solid body, therefore, its weight in air must be divided by the loss of weight which it sustains when weighed in pure water.

The process of finding the specific gravity of any solid body denser than water is rendered very simple by means of the *hydrostatic balance*. When the solid is less dense than water, its weight in that liquid cannot be ascertained directly; but it may be found by attaching the body to another sufficiently dense to cause both to sink.

In like manner, the specific gravity of a solid in the state of powder may be found by placing it in a vessel whose weight in air and in water has been previously determined.

The specific gravity of a liquid may be found in several ways by means of the hydrostatic balance. One way is equivalent to finding the ratio of the density of a suitable solid body first to water and then to the liquid to be experimented on.

Another method is to take a phial of known weight, and weigh it when filled with water; the increase of weight is of course the weight of the water. It is then filled with the liquid, and again weighed, and the weight of the contained liquid thus ascertained. We have then the weights of equal bulks of the water and the liquid, whence the ratio of their specific gravities is known.

For many practical purposes, and especially for determining the specific gravities or *strengths* of spirituous liquors, it is necessary to have recourse to more expeditious methods than that of the hydrostatic balance. In such cases the instrument called an *hydrometer* is employed. [HYDROMETER.]

The specific gravities of the gaseous fluids are usually determined in terms of that of atmospheric air. The difference between the weights of a flask when exhausted of air by means of the air-pump and when filled with the gas gives the weight of the gas which it contains. But experiments of this kind require to be made with great care, as they are much affected by small variations of the temperature, pressure, and hygrometric state of the atmosphere. For a detailed account of the method of proceeding, and the manner of applying the requisite corrections, see Biot's *Traité de Physique*, tome i.

Graying. [SALMON.]

Grazioso (Ital.). In Music, an instruction to the performer that the music to which this

GREAT CIRCLE SAILING

word is affixed is to be executed elegantly and gracefully.

Great Circle Sailing. In Navigation, the shortest distance between two places on the surface of the earth is the arc of a great circle passing through them. If the latitudes and longitudes of the two places are known, this arc may be readily calculated by the common rule in spherical trigonometry for finding the third side of a spherical triangle when the other two sides and the included angle are given. The practical inconvenience of sailing on a great circle arises from the necessity of continually altering the course; this, however, may be partly obviated by taking two or more points on the arc, and finding the latitude and longitude of those points; then, by the common rules of navigation, finding the course and distance from the place of departure to the nearest point marked on the arc: thence the course and distance to the next point, and so on. The sum of the distances described on these several courses will not differ much from the shortest distance. By proceeding in this manner as far as it is practicable, the advantage of sailing close to the arc of the great circle, and thus of shortening the distance, may be obtained without any difficulty. (*Jesans' Navigation.*)

Great Oolite. [*OOLITE.*]

Great Primer. In Printing, the name of a kind of type six sizes larger than that used in this work. [*TYPE.*]

Greaves (Span. *grevas*; in the dialect of Burgundy, *grève* still signifies *skin*). Pieces of armour for the protection of the leg. That they were generally used by the Achæan warriors in the Homeric age, is shown by their common epithet *ἐκρημίδες*, or *well-greaved*. Examples found at Pompeii are of metal highly ornamented. In the fourteenth century they were made of metal or leather, and their Low Latin name was *bainberga*, from the German *beinbergen*.

GRAVES. [*GRAVES.*]

Grebe. [*PODICEPS.*]

Grecian Architecture. [*ARCHITECTURE, GRECIAN.*]

Greek Church, The. Comprises the great bulk of the Christian population of Russia and Greece, Servia, Moldavia, and Wallachia, besides various congregations scattered throughout the provinces of the Turkish and Austrian empires. Some of these acknowledge the patriarch of Constantinople as their head; others are under local patriarchs. The Byzantine patriarch, although possessing a certain spiritual supremacy over such an extensive community, has never ventured to assert any claim to the temporal power so long wielded by his rival at Rome. His ambition was curbed in the first instance by the jealousy of the emperors, with whom he was brought into closer contact; and since the Mohammedan conquest the state of weakness and poverty into which the Christian church in Turkey has been thrown has annihilated all views of aggrandisement. In earlier times, however, the Con-

GREEK CHURCH

stantinopolitan pontiffs clearly showed that they did not lack the will to raise themselves to a station in the East on a level with the growing authority of the popes in the West. The origin of the separation which has now prevailed for many hundred years between two such important sections of Christendom as the Latin and Greek churches, agreeing as they do in most of their fundamental principles, is to be attributed to the rival pretensions set up by the bishops of the two imperial cities, and dates almost from the foundation of the younger capital.

As early as the year 451 the council of Chalcedon assigned Asia Minor, Pontus, Thrace, and the frontiers of Illyricum for the extent of the spiritual jurisdiction of the church of Byzantium, and conferred upon its bishop the honours and privileges which had been already conceded to the pope of Rome. The patriarchs of Antioch and Alexandria maintained at this period an independent authority; but were gradually reduced under the predominant influence of the patriarch of the East. The aggressions, however, of the rival pontiffs did not proceed *pari passu*: the Roman, being farther removed from the imperial authority, which was seated at Ravenna, assumed by degrees a direct temporal authority over the neighbouring districts; and this assumption led the way to the prodigious indirect supremacy which he usurped after the lapse of several ages. The Constantinopolitan, on the contrary, was always strictly watched, and fettered by the proximity of the Eastern emperors; and the extension or declension of the patriarchal authority depended in most cases more upon the particular character of the wearer of the crown than of the mitre. The first doctrinal ground of dispute was the assertion of the Latin church, about the beginning of the ninth century, of the double procession of the Holy Ghost from the Father and the Son. The word *filiogue*, first surreptitiously inserted into the Constantinopolitan creed many years after its promulgation, became the badge of the Western church; but whatever apparent advantage this forgery might give to the opposite party, it is very certain that the other dogma, the procession from the Father alone, had never been declared by a council of the church.

The discussions produced by this controversy were brought to a head by the sudden elevation of Photius, a layman, to the patriarchate, by the command of the emperor. In six successive days he passed through the six preliminary orders: he became successively monk, reader, subdeacon, deacon, priest, bishop, and finally, on the seventh day, was consecrated patriarch; and all this to the violent exclusion of the existing pontiff, Ignatius. The appointment of Photius, who was a man of extraordinary talents, alarmed the Pope. The cause of Ignatius was supported in the West; and the intruder excommunicated by Nicholas I. The thunder of Rome was retorted by a charge, made on the part of Photius against the Latin church, of five distinct heresies. 1. It was objected that

GREEK CHURCH

the Romanists fasted on the Sabbath, or seventh day of the week; 2. That they permitted the use of milk and cheese in the first week of Lent; 3. That they forbade their priests to marry; 4. That they authorised bishops to baptise with the chrism, and forbade the priests; 5. That they had interpolated the creed of Constantinople with the word *filioque*, and held the doctrine therein implied.

These proceedings widened the breach which had already in fact taken place by the formal transference which the emperor had effected of several provinces east of the Adriatic, from the jurisdiction of Rome to that of Constantinople. The Romish party, however, continued still powerful in the East, and the intrigues of the papal see were frequently successful; until in 1054 the mutual excommunications pronounced upon each other by Leo IX. and Cerularius caused the final separation, which has continued to the present day.

The opinions of the Greek church bear considerable affinity to those of the Latin. The fundamental distinction is the rejection of the spiritual supremacy of St. Peter, and the denial of any visible representative or vicar of Christ upon earth. In the view which it takes of the procession of the Holy Ghost, it is at variance not only with the Roman Catholic church, but with the general belief of Protestants also. It recognises, however, the seven sacraments; authorises the offering of prayer to the saints and Virgin; and encourages the use of pictures, though forbidding that of images. It holds in reverence also the relics and tombs of holy men; enjoins strict fasting and the giving of alms, looking upon them as works of intrinsic merit; and numbers among its adherents numerous orders of monks and nuns, but allows, or rather insists on, the marriage of its secular priests. It holds that modified form of the Roman doctrine of the eucharist which is denominated *consubstantiation*; while it admits the doctrine of purgatory, and enjoins the offering of prayers for the dead. It administers baptism by immersion.

The distinctive characteristics of the Greek as contrasted with the Roman church are noticed by Dean Milman in the Introduction to his *History of Latin Christianity*. While the tendencies of the Western Church were chiefly practical, Greek Christianity was pre-eminently speculative, and ceased, with the extinction of Paganism, to be either creative or aggressive. The practical illustration of this difference is to be found in the remarkably stationary character of the discipline, usages, and modes of sentiment, not less than of the doctrines, of the Eastern church even to the present day.

The emancipation of the Russian branch of the Greek church from the centre of authority at Constantinople was gradually effected, and may be said to have been complete in the middle of the fifteenth century. The independence of the church of Greece Proper was recognised by Constantinople in 1850. (Stanley, *History of the Eastern Church*.)

GREENHOUSE

Greek Fire. [FIRE, GREEK.]

Green Cloth, Board of. [HOUSEHOLD.]

Green Lead Ore. The native phosphate of lead.

Green, Scheele's. An arsenite of copper. *Mineral green* is a subcarbonate of copper, and *Brunswick green* an oxychloride of copper.

Green Sickness. [CHLOROSIS.]

Green Vitriol. The metallic salts of sulphuric acid were formerly designated *vitriols*: sulphate of iron was termed *green vitriol*. It is a compound of 1 atom of oxide of iron and 1 atom of sulphuric acid: the crystals contain 7 atoms of water; hence the crystallised salt consists of 36 protoxide of iron, 40 sulphuric acid, and 63 water, and its equivalent is = 139. Sulphate of copper is called *blue vitriol*, and sulphate of zinc *white vitriol*.

Greenfinch: The *Fringilla viridis* of Linnaeus. [FRINGILLA.]

Greenheart. The *Nectandra Rodiei*, a tree of British Guiana, which furnishes a valuable wood known as Greenheart timber. It is also called the Bibiri-tree.

Greenhouse. In Gardening, a house with a roof and one or more sides of glass, for the purpose of containing exotic plants which are too tender to endure the open air during the greater part of the year. The greenhouse being a structure of luxury, ought to be for the most part situated near the house, in order to be enjoyed by the family in inclement weather; and, if possible, it should be connected with the flower-garden, as being of the same character with reference to use. Its length and breadth may be varied at pleasure, but its height should never be less than that of the loftiest apartments of the house to which it belongs. The best aspect is to the south or south-east; but any aspect may be chosen, provided the roof is entirely of glass, and abundant heat is supplied by art. In greenhouses facing the north, however, the more tender plants will not thrive so well in winter: more artificial heat will be required at that season; and the plants should be chiefly evergreens, and other plants that come into flower in the summer season, and grow or flower but little during winter. In most greenhouses the plants are kept in pots or boxes, and set on stages or shelves, in order that they may be near the roof, so as to receive the direct influence of the rays of light immediately on their passing through the glass. An orangery differs from a greenhouse in having an opaque roof, and in being chiefly devoted to plants, which, producing their shoots and flowers in the summer season and in the open air, are set in the orangery merely to preserve them through the winter. Such a structure might with more propriety be termed a *conservatory*; but custom in the present day has applied this term to buildings with glass roofs in which the plants are not kept in pots, but planted in the free soil, and in which a part of them are encouraged to grow and flower in the winter months. [ORANGERY and CONSERVATORY.]

GREENLANDITE

Greenlandite. A variety of the precious Garnet.

Greensand. In Geology, the name given to two series of rocks belonging to the Cretaceous period and found below the chalk. The name is derived from the frequent presence, in these deposits of the cretaceous period, of particles of a silicate of iron of green colour, not unfrequently producing beds of sand of a greyish green tint. The greensands are divided into two groups, the *upper* and *lower*, the gault intervening. [UPPER GREENSAND and LOWER GREENSAND.] These names are not generally adopted by the continental geologists, owing to the absence of the characteristic colour in the representative formations. Thus the upper greensand forms a part of the chalk marl and is hardly distinguished from it, while the lower is commonly designated *Neocomian*.

It must not be assumed that a green colour always signalises the sands here described, or at any rate that it affects their appearance. They are frequently (especially the lower greensand) of the most brilliant and intense red. This is derived from the conversion of the grains of silicate into peroxide of iron, and is quite consistent with the presence of abundant green grains a little away from the surface.

Greenstone. A variety of trap-rock. The constituent parts of greenstone are hornblende and imperfectly crystallised felspar, the felspar being abundant. Augite sometimes replaces the hornblende, producing *dolerite*. [TRAP-ROCK.]

Gregarious (Lat. *gregarius*, from *grex*, a flock). In Zoology, those animals which are found in company with each other; used in opposition to *solitary*.

Gregorian Calendar. The reformed calendar of the church of Rome, introduced by Pope Gregory XIII. in 1582, in which the error of the civil year of the Julian calendar was corrected by the omission of three intercalary days in four centuries, and the moon's age, with the time of Easter, with the other movable feasts depending on it, indicated by the table of epacts. [CALENDAR]

Gregorian Chant. Introduced by Pope Gregory the Great about A.D. 600. These chants have continued in use in the Western church to the present day, and form the basis of our cathedral music. (Hook's *Church Dictionary*.)

Gregorian Epoch. The epoch or time at which the computation by the Gregorian calendar commenced. This was in March, 1582.

Gregorian Telescope. The first and most common form of the reflecting telescope, invented by James Gregory, professor of mathematics in the university of St. Andrew's and afterwards of Edinburgh, and described by him in his *Optica Promota*, published in 1663. [TELESCOPE.]

Gregorian Year. The civil year of the Gregorian calendar. In the Gregorian calendar the common year consists of 365 days, and every fourth year is a leap year, or contains 366 days, excepting the last years of every

GRETNA GREEN MARRIAGES

century of which the number is not divisible by 4. Thus, the years 1700, 1800, 1900, are not leap years; but 1600 and 2000 are leap years, the numbers 16 and 20 being divisible by 4. The period is consequently 400 years, in the course of which there occur 97 intercalations; so that 400 years contain $365 \times 400 + 97 = 146,097$ days, and therefore one Gregorian year consists of 365.2425 mean solar days, or 365 d. 5 h. 49 m. 12 sec. But the true solar year consists of 365 d. 5 h. 48 m. 49.62 sec. The Gregorian year, therefore, errs in excess by 22.38 seconds; but the error is not worth taking into account, as it only amounts to one whole day in 3,866 years.

Gregorite. The Menaccanite of Cornwall, discovered by Mr. Gregor, whose name it bears. A variety of titanite iron-ore.

Grenade (Fr. from its resemblance to a pomegranate). A hollow ball of iron or glass, about two inches and a half in diameter, charged with gunpowder and furnished with a fuse; it is often called a *hand grenade*, being thrown by hand from the parapets of besieged places upon the invaders beneath.

Grenadiers (Fr.). The name given at first to the soldiers who threw grenades; but afterwards conferred on certain troops of the line, distinguished by peculiarities of dress, accoutrements, &c. The name originated with the French in 1667, but was speedily adopted into all the armies of Europe; and wherever it has been introduced, the finest men of a regiment have always been selected to form what is called the grenadier company. Until recently each regiment of the line in our service had a grenadier company; now the name only remains in the 'Grenadier Guards.'

Grès. The French name for a sandstone or a grit. Thus the new red sandstone is called *le nouveau grès rouge*; the grès of Fontainebleau is also a well-known member of the tertiary grès.

Gressorial. In Ornithology, is applied to the feet of birds which have three toes forward, two of which are connected, and one behind.

Gretna Green Marriages. In order to evade the stringency of the English Marriage Law, after the Act of George II., and to enjoy the facilities afforded by that of Scotland [MARRIAGE, LAW OF], couples from England used to have the ceremony performed at the first place which they could reach in Scotland. Gretna Green, on the western border near Carlisle, was the best known and most convenient. The ceremony merely amounted to an admission before witnesses that certain persons are man and wife, the only condition necessary to render it a valid marriage being that it should be either preceded or followed by cohabitation. This facility was abolished by 19 & 20 Vict. c. 96, which requires twenty-one days' previous residence to render such marriage valid. The number of these marriages was stated to be on the average 300 or 400 a year at Gretna alone; but with those which took place at other

GREWIA

places along the border amounted to about 500 a year.

Grewia (after Dr. Grew, a physiological botanist of the seventeenth century). Of this genus of *Tiliaceae*, two species, *G. supida* and *asiatica*, yield small red acid fruit, commonly used in India for flavouring sherbet. Some of the species have a fibrous inner bark, which is used for rope-making, &c.; and the wood of *G. elastica* is very strong and elastic. They are widely dispersed, but not found in America.

Grey Stone Lime. The name given by London builders to the lime made from the chalk marl quarried at Dorking, Merstham, or Godstone. It is of the same nature as the *clunch* lime of the midland counties; it is moderately hydraulic, containing about eight per cent. of the silicate of alumina. It swells a good deal in slaking, and gives out much heat.

Greywacke. [GRAUWACKE; GEOLOGY.]

Grias. The Anchovy Pear of Jamaica is the produce of *G. cauliflora*. The fruits are pickled and eaten like mangos. The genus belongs to the *Barringtoniaceae*.

Griffin (Gr. γρύψ). A fabulous animal represented with the body and feet of a lion, the head of an eagle or vulture, and as being furnished with wings and claws. The griffin belongs more to romantic than classical mythology. It plays a prominent part in the fairy tales and romances of the middle ages; and, like the dragon which was fabled to guard the golden apples of the Hesperides, its chief duties consisted in watching over hidden treasures, and in guarding captive princesses, or the castles in which they were confined. It has been adopted into the language of heraldry, where it constitutes a prominent feature in the armorial bearings of many princely and noble families.

Griffiths' Mixture. The *mistura ferri composita* of the London *Pharmacopœia*; it is a useful ferruginous tonic, deriving its efficacy from the prot carbonate of iron.

Grilse. [SALMON.]

Grimace (Fr.). In Painting and Sculpture, an unnatural distortion of the countenance, from habit, affectation, or insolence. The ancient comedians wore masks fashioned into the most exaggerated grimaces. (Ficroni, *Le Maschere Sceniche* &c. d'Antichi Romani, Rome 1736.)

Grinders. [TEETH.]

Gripe. The fore foot of a ship.—*To gripe*, the tendency of a ship to bring her head up to the wind when carrying sail on the wind.

Gripes. On Shipboard, the apparatus of ropes, hooks, &c., by which boats are fastened to the upper deck during stormy weather.

Grisette (Fr.). Originally a dress of coarse grey cloth; but the word was afterwards applied to denote the women who wore them.

Gristle. [CARTILAGE.]

Grit (A.-Sax. greot). Any variety of stone made up of minute grains cemented together, may conveniently be called by this name. *Coal*

GROSSULARIACEÆ

grit is a sandstone of the coal measures; *calc grit*, a limestone of the oolitic series.

Groat (Dutch grote, originally grote schware, the great schware, as distinguished from the little schware, of which there were five in the grote or groat). An old English silver coin equal to 4d. of our present money. It was introduced by Edward III. about the year 1361, and has lately been again adopted and issued from the Mint: the first coinage of these modern silver groats or fourpenny pieces took place in 1835.

Groats. The seeds of Oats prepared as an article of food, by depriving them of their husks or hulls.

Groin. In Architecture, the line formed at the intersection of two arches which cross each other at any angle.

Grommet. On Shipboard, a ring or loop made at the end of a piece of rope by inter-splicing the strands.

Groningenists. In Ecclesiastical History, a subdivision of the sect of Anabaptists.

Groom (Dutch grom, a youth). A name now usually applied to servants who are employed about horses. The *groom-porter* was an officer of the royal household in the lord steward's department, whose place is said to have succeeded that of the master of the revels. Groom is still the denomination of several officers of the royal household, chiefly in the lord chamberlain's department; such as grooms in waiting, groom of the stole or robes, &c. &c.

Groove (Dutch, groeve, a furrow; Ger. grube, a pit, from graben, to dig). In Architecture, a sunken rectangular channel. It is usually employed to connect two pieces of wood together, the piece not grooved having on its edge a tongue, or projection, whose section corresponds to and fits the groove.

Groove. Every rifled firearm has two or more grooves, cut in a spiral direction in the interior of the barrel. The parts of the barrel between the grooves are called *lands*.

Gross. In Commerce, the number of twelve dozen.

Gross Weight. In Commerce, the weight of goods with that of the dust and dross, or of the cask, &c., in which they may be contained. Out of this weight the allowance is made for tare and tret.

Grossbeak. [FRINGILLA.]

Grossularia (Lat. grossulus, a small fig. A green garnet found in Siberia.

Grossulariaceæ (Grossularia, an old name of one of the genera). A natural order of shrubby Exogens, natives of most parts of the world, excepting Africa and the tropics, and distinguished among epigynous Exogens by their pulpy fruit and parietal placentæ. They were formerly confounded with *Cactaceæ*, and have been placed by Von Martius between *Saxifragaceæ* and *Onagraceæ*; but Lindley makes them the type of a distinct alliance. The Gooseberry, *Ribes Grossularia*, and the Currant, *Ribes rubrum* and *nigrum*, are well-known fruits of this order, to which also belong many beautiful hardy shrubs common in our gardens.

GROTESQUE

Grotesque (Fr.). In the Fine Arts, a term applied to capricious ornaments, which as a whole have no type in nature; consisting of figures, animals, leaves, flowers, fruits, and the like, all connected together. So called from being discovered in the ancient grottoes. [ARABESQUE.]

Grotto (Ital.). The name given to subterraneous natural excavations formed in the heart of mountains or other places. Many of these cavities are famed for the mephitic exhalations that issue from them, and to this class belongs more especially the Grotto del Cane, near Naples; but there are others not less celebrated for their beauty and grandeur, of which the grottoes of Antiparos and Fingal are well-known examples. In picturesque gardening, the term is applied to an artificial or ornamental cave or low building intended to represent a natural grotto.

Ground (Ger. grund). In the Fine Arts, a word of various application. In Painting, it is the first layer of colour on which the figures or other objects are painted. The term is also applied to the different distances in a picture, as fore-ground, middle-ground, background. In Sculpture, it is the surface from which, in *relievi*, the figures rise. In Architecture, it is used to denote the face of the scenery or country round a building.

Ground Bait. Balls made of greaves, bran, boiled grain, gentles, &c., mixed up with clay and thrown into the water, by which the fish are brought together upon those spots which the angler selects for his sport.

Ground Gru or Ground Ice. Ice formed under peculiar circumstances at the bottom of running water.

The theory of the formation of ground ice is attended with some difficulty. Dr. Farquharson, who has carefully investigated the facts, and given the results of his observations on the ground gru of the rivers Don and Leschal in Lincolnshire, in two papers printed in the *Phil. Trans.* for 1835 and 1841, is of opinion that the ice is formed when the water has gone down to the temperature of the freezing-point in consequence of the bottom being cooled to a still lower temperature through the effect of radiation, in the same manner as dry land, under a clear sky, is cooled below the temperature of the air; and in corroboration of this opinion he states, that the formation never occurs excepting under a clear sky, and does not take place where the stream is shaded by bridges or high banks. It has been objected to this theory, that ground ice has been observed in the Neva under a thickness of three feet of surface ice, and an additional covering of three feet of snow, circumstances under which radiation could not take place; but Dr. Farquharson remarks, that this fact can form no valid objection to his explanation, unless it were ascertained that the ground ice was formed *after* the surface ice and fall of snow, and not before. Recent researches on heat have, however, rendered this hypothesis untenable, since

GROUP

it has been proved that water is absolutely intrascalent to rays of *obscure* heat such as those which Dr. Farquharson supposes to issue from the bottom of the stream. M. Arago, in the *Annuaire du Bureau des Longitudes* for 1833, after stating the observations which had then been collected on the subject, attributes the formation to three circumstances: 1. In a body of water in motion, the temperature of which is below 39° of Fahrenheit (under which water becomes specifically lighter by a further diminution of temperature), the eddies of the current throw down the coldest parts which, in still water, would remain at the surface, so that the whole stream from the surface to the bottom acquires the same temperature through this mechanical action. 2. The aptitude for the formation of crystals on the stones and asperities at the bottom. 3. Less impediment to the formation of crystals at the bottom, in consequence of the comparatively greater stillness of the water. On this subject see, in addition to the works above referred to, Colonel Jackson's paper on the Congelation of the Neva, in the *Journal of the Royal Geographical Society*; Mr. Eisdale's, in the *Edinburgh New Philosophical Journal*, vol. xvii.; Mr. Weitz's, on the Ground Gru of the Siberian Rivers, in the *London Geographical Journal*; Mr. Adie's and Prof. Frankland's on Ground Ice, in the *Journal of the Chemical Society*, vol. xiv. pp. 111 and 113.

Ground Plate or Sill. In Architecture, the piece of timber which forms the lower part of a timber building, into which the upright posts or principal timbers frame.

Ground Swell. An undulation of the ocean caused by the continuance of a heavy gale of wind. Ground swells are rapidly transmitted through the water, sometimes to great distances, and even in direct opposition to the wind, until they break against a shore, or gradually subside in consequence of the friction of the water. They indicate, by the direction of their movement, the quarter in which a storm has raged; and occasionally they are observed to come from various points of the compass at the same time.

Ground-tackle. The name applied on Shipboard to all the ropes, &c., connected with the anchors or other mooring apparatus.

Grounds. In Architecture, pieces of wood let in flush with the plastering, for which they serve as a guide; the mouldings and other finishings are nailed to them.

Groundsel. The common name for the genus *Senecio*, but more particularly applied to one of our commonest weeds, *Senecio vulgaris*, a plant used in feeding cage-birds.

Group (Fr. groupe). In Painting, an assemblage of objects, whose lighted parts form a mass of light, and their shaded parts a mass of shadow: the word is also used to denote any adjoining assemblage of figures, animals, fruits, flowers, &c. In speaking also of objects of different sorts, it is usual to say that one object *groups* with another. Lights in groups should,

GROUSE

as well as shadows, be connected together, or the necessary repose will be wanting. In Sculpture, the word *group* is applied to a design in which there are two or more figures. In Music, *group* signifies a number of notes linked together at the stems.

Grouse. [TETRAO.]

Grout. In Architecture, mortar reduced to a state of fluidity by the addition of water; also a mixture of plaster (or fine stuff) putty (or coarse stuff) used to finish off the best ceilings, and sometimes for setting walls when such finish is required.

Groynes. High timber defences erected on the exposed shores of the sea, or of rivers, when they are composed of such materials as can be easily removed by the action of the currents that may beat upon them. The term is also applied to the little jetties sometimes erected to defend the banks of rivers when threatened with destruction by the washing away of the shore. A groyne is, in fact, a projection that is carried out from the banks of the sea, or of a river, in a direction perpendicular, or occasionally inclined, to the set of the current; and it is supposed to act in the first case by retaining the shingle, which has a tendency to move in the direction of the prevailing wind; and in the latter, by diverting the channel in the direction required. Groynes are much used in the neighbourhood of Brighton, Dover, Harwich, Yarmouth, &c.; they are occasionally employed in river defences, as in the course of the Rhine, the Orne, the Midouse, &c.; but engineers have of late entertained the opinion, that they produce as much harm as good in these positions, by creating a back-water on the down side, unless they are so close together as to amount practically to a continuous parallel wall. (Minard, *Cours de Construction des Canaux et des Rivières*, &c.)

Gruidee. The name of the family of wading birds represented by the stork (*Grus*).

Grummet Wad. In Artillery, a wad formed of a circle of rope, rather less in diameter than the bore of the gun for which it is intended, with two cross-pieces projecting a little beyond the exterior of the circle. These wads are used in firing cold shot from smooth-bored guns, when the elevation is less than 3°.

Grus (Lat. *the Crane*). One of the modern constellations in the southern hemisphere. [CONSTELLATION]

Gryllidæ (Lat. *gryllus*, Gr. γρύλλος, *a cricket*). The name of the family of locusts, having the genus *Gryllus* for the type. [LOCUST.]

Grypanium (Gr. γρυπνός, *curved*). In Ornithology, the *rostrum grypanium* is that form of beak in which the culmen is more or less carinated, and is so continued to the apex of the incurved maxilla.

Gryphæa (Gr. γρυπός). A genus of Ostracæan Bivalves, remarkable for the curvature of the apex or beak of the shell; it is chiefly represented by fossil species, one of which, *Gryphæa virgula*, characterises the Kimmeridge

GUARANA

clay, near Oxford, and the upper oolite of parts of France.

Gryphosis (Gr. γρυπός). A growing inwards of the nails.

Guaco. The South American alexipharmic, *Aristolochia Guaco*. The same property has also been attributed to *Mikania Guaco*.

Guaiacum (Guaiac, the Guiana name). This genus of *Zygophyllaceæ* comprises the tree which yields *Lignum Vitæ* and resin *Guaiacum*; the first remarkable for its hardness and ponderousness; the second used medicinally as a stimulant in chronic rheumatism, and as an alternative. This tree is called *G. officinale*, and produces pinnate leaves and very pretty blue flowers. The resin is obtained by notching the stem; it has some chemical peculiarities which distinguish it from the common resins, especially its property of becoming blue and green by the action of certain oxidising substances. (Brande, *Phil. Trans.* 1806.) Its constituent resins, and the products of its dry distillation, are also in many respects peculiar.

Guana (Port. corrupted from *Iguana*). The local name applied to a large American lizard, the *Iguana tuberculata*, or *Lacerta Iguana* of Linnaeus.

Guanocho. [AUCHENIA.]

Guano. The dried dung of seafowl, which has accumulated for ages on certain tropical islands. It was introduced into English agriculture in 1840, and the importation, which amounted to 2,000 or 3,000 tons in 1841 and 1843, has varied from 100,000 to 300,000 tons per annum ever since. It is used at the rate of from one to three cwt. per acre as a top dressing for wheat and other corn crops; and it is also of great service as an addition to the farmyard manure for various green crops. Its use has prepared the way for the extension of the artificial manure manufacture: and the two together have almost revolutionised English agriculture, and greatly added to the productiveness of English soil. It is an excellent manure, abundant in nitrogenous compounds, which seem principally to consist of urate of ammonia, and of the products of the decomposition of that salt; but it is largely adulterated, and many samples come into the market which are spurious.

Guarana. The *Paulinia sorbitis*, a South American tree, yield seeds which, when pounded, made into cakes, and dried in the sun, form Guarana bread. Guarana is extensively used in Brazil, Guatemala, Costa Rica, and other parts of South America, as a nervous stimulant and restorative, and also as a material for making a refreshing beverage. The active principle of Guarana is said by Martius to be identical with theine; but, as far as is known, no other substance yields it so abundantly, the amounts being 5·07 per cent. as against good black tea, which yields 2·13, and coffee from 0·8 to 1·00. The Guarana is carried in the pocket of almost every traveller; and when required, a small portion is grated on a fish bone or scale carried for the purpose, and being added to water, is taken as a substitute for tea.

GUARANTEE

Guarantee. In Law, an undertaking to answer for the failure of another. By the Statute of Frauds, a person is not liable on a special promise in the nature of a guarantee unless a written agreement, or memorandum of such promise, shall be signed by the party making the promise, or some person lawfully authorised by him. See also 19 & 20 Vict. c. 97.

Guard, the Imperial. Was formed by the emperor Napoleon I. in 1804, from a small corps of life-guards (as they might be termed) which had served to defend the Convention, the Corps Législatif of 1795, the Directory, and afterwards the Consulate. Its augmentation and equipment became afterwards one of Napoleon's favourite pursuits. In 1809, he divided it into the old and new guard, and as soldiers could not be enrolled in the old guard except after serving four campaigns in the line with distinction or from the preparatory corps called the young guard, it was an institution of the highest military policy. In the end of 1812, the Imperial Guard, old and young, consisted of 56,000 men; and its further increase was only prevented by the calamities of the following years. At the Restoration, the soldiers of the young guard returned to the line; those of the old guard were formed into royal regiments. The Imperial Guard was revived by Napoleon III. in 1854, and portions of it took part in the Crimean war in 1855. It consists of infantry, cavalry, and artillery. The Russian imperial guard forms an entire corps d'armée, exceeding 50,000 in number.

Guard, National, of France. This famous institution was first devised by the Municipal Committee of Safety of 1789, which sat at the Hôtel de Ville, in Paris, before the taking of the Bastille. The corps which was then raised at first carried green colours, afterwards replaced by the tricolor. It was more fully organised by a decree of September 1791, to be raised by voluntary enlistment, both in Paris and the departments, in the proportion of one man out of every twenty citizens. The staff of the national guard was dissolved by the Convention after the 13 Vendémiaire (1795), and it was placed under control of the military authorities. Napoleon made of the national guard a species of military nursery, and large portions of it volunteered in 1813 to act beyond the frontiers. Under the Restoration the national guards were deprived of the privilege of choosing their own officers; and in 1827, in consequence of their public demands for the dismissal of the ministry (Villele's), they were dissolved. In 1848, they were reconstituted and enlarged to the number of 100,000. Their constitution was again entirely altered in 1852, and they were placed under government control. Every Frenchman is bound to this service from fifteen to fifty.

Guard, Yeomen of the. Were first raised by Henry VII. in 1485, and appear to have been the first standing military corps ever set on foot in this country. They were at first

GUARDS

fifty men, armed with bows, but afterwards some carried halberds, and later arquebusses. These were exchanged for partisans (which they now carry) in the reign of William III. [**BEEF-EATER.**]

Guardian. In Law, he who has the custody of such persons as are incapable of directing themselves, and especially of infants. These may now be said (on the father's death) to be of five classes: 1. Testamentary, or appointed by will; 2. Customary, by local usage; 3. Ad litem, or appointed by a court in order to conduct legal proceedings; 4. By appointment of chancery; and 5. In tort or by intrusion, as when a person wrongfully intrudes in the management of an infant's estate, he must account in chancery as if he had been a guardian. The old kinds of guardianship at common law are too nearly obsolete to need recapitulation. In France, as in England, guardianship (tutelle) lasts until the full age of twenty-one, unless in case of marriage or judicial emancipation.

Guardian of Spiritualities. In Ecclesiastical Law, the person to whom the spiritual administration of a diocese is intrusted during the vacancy of the see.

Guardian of Temporalities. A person appointed by the king during the vacancy of a see to take care of the goods and profits of the same, and deliver an account to the Exchequer.

Guardians of the Poor. Officers appointed in each union, under the Poor Law Amendment Act, 4 & 5 Wm. IV. c. 76, to superintend the administration of that law. [**POOR LAW.**]

Guards (through the French garter, from the Teutonic *wardian*, to *ward* or *keep*). Troops attached to the person of the sovereign. Body-guards have been an inseparable accompaniment of monarchy from the earliest ages: the Assyrian and Persian monarchs employed them. The corps of Argyraspides, or silver-shields, were selected by Alexander out of the bravest men of his army. The Roman emperors had their Prætorian guard. Napoleon first created a small troop of body-guards, with the title of Guides, while he was yet only general, in his first Italian campaign. From this arose by degrees the great institution of the Imperial Guard. [**GUARD, THE IMPERIAL.**] In England, the guards (otherwise called *household troops*) consist of the life-guards, the royal regiment of horse-guards, and three regiments of foot-guards. The first English body-guards were embodied in 1485; the horse-guards in 1550; and the foot-guards in 1660. Many of the European sovereigns, before the French Revolution, had small corps of foreign troops which served in this capacity. Thus the French kings had, in early times, a body of Scotch guards, termed *archers*; at a later period, a body of Swiss guards, called the Cent-Swiss; and after the Restoration of 1815 several battalions of Swiss guards were organised for the same service. This system has almost disappeared, since the troubles of the Revolution have introduced a spirit at once more military and more national into the coun-

GUARDSHIP

cils and populations of Europe. The pope still retains his Swiss guards.

Guardship. In a British port, a large ship of war on harbour duty appointed to protect the ships lying unarmed in the port.

Guava. The fruit of the *Psidium Guaiava*, of which two forms, called *pomiferum* and *pyriferum*, are known, and from the fruits of which a jelly is made in the West Indies. [PSIDIUM.]

Gudgeon (Fr. goujon). The common name of a small species of the Cyprinoid family of soft-finned fishes; having, like the barbel, cirri or feelers at the mouth, and both the dorsal and anal fins short, but without a strong bony ray at the commencement of either. The species consequently forms the type of a distinct sub-genus called *Gobio*.

GUDGEON. On Shipboard. [GOODGEON.]

Gudgeons. Any short pin or bearing part of a piece of machinery. The laws of torsion are principally directed to ascertain the size to be given to these parts of machinery. (Hodgkinson, Tredgold, Rennie, &c.)

Guebors or **Guebres** (i.e. Giseurs, *infidels*). The sectaries of the ancient Persian religion, of which the chief peculiarity is the worship of fire, are so termed by the Mohammedans. They still exist in some of the southern and eastern districts of Persia; and a colony of them, long established at Bombay and other parts of the western coast of India, has attained to wealth and distinction. These are termed in India *Parsees*, from the nation from which they originally sprang. The Guebres explain the worship of fire by professing to regard it as a symbol only of the Divinity. Their sacred books are termed the *Avesta*. [PARSEES.]

Guelder Rose. The *Viburnum Opulus* of botanists. It is remarkable for having the outer flowers of its cymes enlarged and neuter; in one variety, called the Snowball-tree, the whole cyme becomes barren, forming a globose head of snowy flowers. This variety is commonly planted in shrubberies, and bears the names of Rose de Gueldres, Pelotte de Neige, Boule de Neige, &c.

Guelph, Order of, or Royal Guelphic Order. An Hanoverian order of knighthood, founded in 1816 by George IV., then Prince Regent. It consists of grand crosses, commanders, and knights, both civil and military.

Guelphs. In Italian History, during the middle ages, a political party, the feuds between which and the opposite party of the Ghibellines long distracted the country. The former name is derived from that of the great German house of the Welfs or Guelphs. These, in the twelfth century, were dukes of Bavaria, who carried on war in Germany with the house of Hohenstauffen, from one of whose castles (Weiblingen) the name Ghibelline is supposed to have been derived. The latter house having become the ruling power in Germany under Frederick I., that prince invaded Italy in order to reassert the rights of the empire; and thus these party names, first used in a German feud, were trans-

GUILANDINA

planted into that country. The chief adversaries in Italy of the house of Hohenstauffen were the popes, who thus became the heads of the Guelph party; and in the thirteenth century, when Frederick II. was involved in contests with several successive pontiffs, the struggle between the two became a contest between the temporal and spiritual power. In that instance the latter prevailed; but the Ghibellines remained, notwithstanding, powerful, especially in the north of Italy; and, in the beginning of the following century, the invasion of the emperor Henry of Luxemburg added considerably to their power. In the early part of that century the leading Ghibelline powers generally were, Milan under the house of Visconti, Verona under that of La Scala, and the Aragonese kings of Sicily; the chief Guelph states, the republic of Florence, the Angevin kings of Naples, &c. Other states were alternately under the control of the two parties as they in turn predominated. At this time the poet Dante, who had embraced Ghibelline principles; not merely on party grounds, but from exalted political speculation, threw the lustre of his genius over the civil feuds of his age. In the course of the fourteenth century, especially after the removal of the papal seat to Avignon, the original principles of the two parties were entirely lost; while the names continued, and factions bearing those appellations constantly agitated the Italian cities and monarchies down to the middle of the fifteenth century, or even to a still later period. (Raumer, *Geschichte der Hohenstauffen*; Sismondi, *Republiques Italiennes*.)

Guenon. [CERCOPITHECUS.]

Guerilla (Span. *little war*). Petty warfare, carried on without a regularly organised army. The plan of harassing the French armies by the constant attacks of independent bands, acting in a mountainous country, was adopted in the north of Spain during the Peninsular War. It was first reduced into a kind of system in 1810. (Napier's *Peninsular War*, book ix. chap. i.) The bands which conducted this desultory warfare were called *partidas*: the name *guerilla* is, by a misapplication of the term, frequently applied to them.

Guide (Fr.). In Music, the leading part in a canon or fugue.

Guidon (Fr.). The flags or colours of dragoon regiments are called *guidons*. They are of silk, the first or royal guidon crimson, the regimental or second guidon the colour of the facings of the regiment. From Markham's *Soldier's Accidence*, 1646, we find that the guidon was the first flag of a commander of horse, who when he performed good service became permitted to carry a cornet, which was a guidon with the swallow-tail cut off, and if he was very gallant his cornet was cut square into a banner.

Guidones or **Guides**. A society of priests, established by Charlemagne at Rome, to conduct pilgrims to Jerusalem, and otherwise to help them in their pilgrimage.

Guilandina (after M. Guilandin). The

GUILD

Guilandina Bonducella, an Indian tree, produces hard seeds called *nicker nuts*, which are strung into necklaces, rosaries, &c. The kernels are reputed to have tonic and febrifugal properties; as also the roots. It forms a prickly trailing tree of the Leguminous order.

Guild or **Gild** (Sax. *gildan*, to pay; perhaps from payments made by a member of a guild on admission). A fraternity or association, generally of merchants. The Collegia Opificum of the later Roman empire appear to have been societies of this kind, in which a body of artisans or traders exercising the same craft were united together for purposes of mutual assistance, and possessed what we should term corporate rights. The Anglo-Saxon guilds were voluntary associations for various purposes, religious and social as well as commercial. The oldest English guild of which the history is at all ascertained is said to have been the Cnighthen guild of London, which has been thought by its name to have been a military company; but this is doubtful, and its history is extremely obscure. But the more important guilds of later times have been all mercantile. The guild-merchant, in many boroughs of England, seems to have been a trading society, into which all persons wishing to exercise trade within the borough were obliged to be admitted; and hence, in process of time, the freedom of the borough, which originally depended upon mere inhabitancy, became connected with admission to the guild, and the guild and corporate body of the borough became coextensive. A more remarkable change took place in the constitution of London, where the several trading companies by degrees so completely engrossed the government, that admission into one or the other of them (the liveried companies) became a necessary qualification for the exercise of municipal rights; while some relics still remain (such as the division of the city into wards) of the more ancient state of things. The name *guild* is still preserved in the ancient boroughs of Scotland, and the dean of guild is the second municipal magistrate of a Scottish borough. The *zünfte* of German cities, and the trading companies of those of France and Italy, have acted an equally important part in the history of those countries.

Guillomot. [URIA.]

Guilloche (Fr. *guillochié*). In Architecture, an ornament composed of curved fillets, which by repetition form a continued series.

Guillotine (Fr.). The name given to the instrument of capital punishment used in France; so called from Joseph Ignace Guillotin, by whom it was introduced into that country. This person was born at Saintes, and became a physician at Paris, where he obtained a certain celebrity in the early period of the Revolution by the strong part which he took in favour of the rights of the *Tiers-État*. He was in consequence elected

GULDIN'S THEOREMS

a deputy to the National Assembly. When that body was occupied in its long discussions relative to the reform of the penal code (in 1790) Guillotin proposed the adoption of decapitation—up to that time used only for nobles—as the only method of capital punishment. From sentiments of humanity he recommended the employment of a machine which had been long known in Italy under the name of *mannaja*, and in other countries also; for something much resembling it had been used in Scotland [MAIDEN], and in England within the jurisdiction of the borough of Halifax. The Assembly approved the idea, and the machine was adopted, to which the Parisians have given the name of *Guillotine*, and of which Guillotin is most erroneously supposed to have been the inventor. It consists of two upright pieces of wood fixed in a horizontal frame; a sharp blade of steel moves up and down by means of a pulley in grooves in the two uprights; the edge is oblique instead of horizontal. The criminal is laid on his face, his neck immediately under the blade, which severs it at a blow from his body. It is equally a vulgar error that Guillotin perished by the instrument which bears his name. He was imprisoned during the Reign of Terror, but released at the revolution of July 1794; and died in 1814, after founding the association termed the Academy of Medicine. (See the articles on this subject in Croker's *Essays on the French Revolution*.)

Guinea. An English denomination of money; formerly a coin, but now disused. Its value is 21s. The coin weighed 129½ grains, and contained 118·7 grains of pure gold. Guineas were first coined in the reign of Charles II. (1662) of gold brought from Guinea; whence the name.

Guinea Hen. [MILVAGRIS.]

Guinea Pepper. A species of *Capsicum*.

Guinea Pig. [CAVIA.]

Guinea Worm. The *Filaria medinensis*. A worm which affects the skin, especially of the legs, in warm climates. Whilst it remains under the skin, this worm produces little uneasiness, till a part suppurates, and it puts out its head; much pain is experienced on attempting to draw it out, especially if it be broken.

Guisards. In Scotland, actors in masquerades, answering to the Morrice dancers of England.

Guitar (Lat. *cithara*, Gr. *κίθαρα*). A musical stringed instrument, the invention of which is attributed to the Spaniards. The strings are stretched over a body much larger than the violin, but of somewhat similar shape; the strings, which are more in number than in the violin, are not carried over so high a bridge, are struck or pulled with the fingers.

Gula. In Architecture. [GOLA.]

GULA (Lat.). In Zoology, the region of the throat nearest the lower jaw.

Guldin's Theorems. These theorems given originally by Pappus, and merely repro-

GULES

duced and verified by Guldinus in his work *De Centro Gravitatis* 1635-41, form the foundation of the so-called Barycentric method of determining the superficial area, and the volume of a surface of revolution. They may be thus enunciated:—

1. The area of the surface of a solid of revolution is equal to the rectangle under the generating arc, and the circumference of the circle which the centre of gravity of this arc describes. 2. The volume of a solid of revolution is equal to that of a prism, whose base is bounded by the generating curve, and whose altitude is the circumference of the circle described by the centre of gravity of the space which this curve encloses.

The demonstrations of these theorems were not given by Guldinus; they are, however, simple, and will be found in most treatises on Mechanics.

Gules (Fr. *gneules*; it is said from the red colour of *gneule*, the *throat*). In Heraldry, red; one of the colours, or tinctures, employed in blazonry. It is equivalent to ruby among precious stones, Mars among planets. In engraving, it is represented by a vertical line.

Gulf (Ital. *golfo*, Gr. *κόλπος*, Mod. Gr. *κόλπος*). In Physical Geography, a portion of the sea nearly enclosed by land. There is little essential difference between bays and gulfs, but the former name is more generally applied to deep indentations of the land whose opening towards the ocean is as wide as any part of the inlet, whereas gulfs have narrow entrances. Other great enclosed portions are called Seas [which see].

Of all gulfs, the gulf of Mexico is the most complete and characteristic. [MEXICAN GULF.] It is the most nearly enclosed as well as the largest. The Persian gulf is large, and very nearly enclosed, lying between Arabia and Persia, and receiving the waters of the Euphrates. The gulf of Siam is much more open.

Gulf Stream. This name is given to a stream current, of extraordinary climatal importance to Europe, which comes out of the gulf of Mexico, between the islands off the coast and the peninsula of Florida, and thence within the Bahama bank, parallel to the American coast, until it meets the St. George's and Nantucket banks, when its course is deflected eastwards. After passing the southern extremity of the great bank of Newfoundland, it runs in the same direction to about 38° west longitude, within the parallels of 35° and 43° north. At this point the main stream turns to the south-east and south as far as the Azores, after which it is lost.

But although the main stream is thus deflected, its influence extends much further. Portions of it reach to Iceland, and wash the shores of the British islands, where tropical fruits have been sometimes landed; and there can be no doubt that the permanent influence of this current has produced the genial climate of Western Europe, as compared with the climate in corresponding latitudes on the west

GUM-TREE

coast of the Atlantic, or on either coast of the Pacific.

The whole range of the Gulf Stream is estimated at about 3,000 miles in ordinary years. It occupies about seventy-eight days in its progress, the average rate of motion per hour being thus a little more than a mile and a half. The velocity, however, varies greatly, being as much as five miles an hour as it issues from the gulf of Florida, and not more than ten miles per day near the Azores.

The temperature varies, but the Gulf Stream is everywhere warmer than the proper temperature of the ocean at that point. As it comes out into the Atlantic, it is from 86° to 89° Fahr., and is only reduced to 84° when it has travelled ten degrees of latitude. After that, as it crosses the Atlantic it cools steadily, but always retains a part of its initial heat, and is constantly warmer than the ocean adjacent. The warm moist air over this current of hot water, when it is crossed by cold currents coming from the icy regions to the north, is at once converted into mist, and thus the course of the stream is in some parts marked by cloud and rain.

Parts of the Gulf Stream, nearer the American coast than the European, are sometimes actually crossed by icebergs, proving that the warm current is comparatively superficial, and that a cold current sets at right angles to the direction of the stream, near enough to the surface to govern the course taken by the larger and deeper icebergs.

Gulf-weed. The *Sargassum bacciferum*, which is found floating in the Atlantic, and occupying more than a quarter of a million of square miles. The origin of this mass of seaweed has not been ascertained.

Gull. [LARUS.]

Gulo (Lat. *a glutton*, from *gula*, the gullet). A genus of Plantigrade Carnivora, the type of which, *Gulo arcticus*, exists in the Boreal regions of the Old and New Worlds. Its fur, under the name of *wolverene*, forms an extensive object of commerce to the Hudson's Bay trappers. The grison (*Gulo vittatus*) and the taira (*Gulo barbatus*) are found in South America.

Gum (Gr. *κόμμη*). A vegetable product, distinguished by solubility in water, and insolubility in alcohol; it is tasteless and inodorous. Gum arabic, which is the produce of the *Acacia vira*, may be taken as a sample of the purest form of gum. It is imported from Barbary and Morocco. Its specific gravity is 1.45. Its solution is viscid, and is termed *muilage*. Gum is used as a demulcent in medicine, and for giving gloss and stiffness to linens, silks, &c. It consists of carbon 41.4, oxygen 52.09, hydrogen 5.51; or, in other terms, of 41.4 carbon and 58.6 water. [TRAGACANTH.]

Gum Resin. An exudation from many trees, composed of a mixture of gum and resin, or of a substance intermediate between the two.

Gum-tree. The popular name of *Eucalyptus*, an extensive genus of trees of the Australian continent, many of which furnish valuable timber.

GUN

Gun (for the origin of this word, see **CANNON**). Under this general term most of the species of firearms are included, the pistol and mortar being almost the only exceptions. Guns, or cannon, began to be used in Europe early in the fourteenth century; and in the accounts of Edward III. in 1346, there is mention of a *handgonne*. The handgun was a barrel on a wooden stock, and was gradually developed into the musket. Muskets were at first of a very clumsy construction, being so heavy that they could not be levelled and fired from the shoulder; accordingly the soldier was provided with a rest, which it was necessary to carry along with him and plant in the ground in order to support the weapon before it could be used. The gun was generally fired with a match; sometimes by means of sparks generated by the revolution of a notched wheel of steel, placed directly above the pan containing the priming. Muskets with rests were employed so late as the civil wars in the time of Charles I.; afterwards a lighter matchlock musket came into use; and about the beginning of the last century the troops throughout Europe were armed with firelocks.

The barrel forms the essential part of the gun; and the first requisite to a good barrel is strength in the material of which it is made, for safety in using it depends mainly on this quality. Old horse stub-nails are much in request for the formation of musket barrels, and are sold at a high price to the barrel-forgers. Formerly the best gun barrels were made in Spain; and their superiority was attributed to the excellency of the iron made use of, which consisted almost exclusively of stub-nails, and the old shoes of the horses and mules: but the barrels now made in this country are not inferior to those of any country in the world. The method of making the barrel is this: The iron is first formed into a thin flexible bar, something like a cooper's hoop, and when heated is plied or twisted round a mandril, much in the same manner as a ribbon of leather is turned round the handle of a whip. The Damascus barrels, prized for their beauty, though inferior in strength, are composed of iron and steel in certain proportions laid crossways, and hammered together the whole length of the barrel. After the barrel has been forged, the inside is rendered smooth and perfectly cylindrical by boring. The exterior is smoothed by turning in a lathe.

By Act of Parliament every gun barrel offered for sale must be tried by a certain quantity of powder and weight of shot according to its size; but the best gunmakers do not trust to this legal test, and subject them to a severer trial by water-proof. For fowling-pieces and other guns of the best description the flint lock is now laid aside, and the percussion lock almost universally substituted.

The principles of the construction of guns or cannon have lately been the subject of the closest investigation. The main points to be attended to in the manufacture of a gun, whether smooth-bored or rifled, are: 1. The quality of the metal; 2. The form and length of the bore;

3. The exterior form of the gun, depending on the weight and distribution of the metal; 4. The preponderance and position of the trunnions.

1. The metal should be hard, elastic, and tenacious; no one of these properties must be sacrificed for the sake of the others. 2. The form of the bore is cylindrical, modified for rifled guns: and in all muzzle-loading guns a certain amount of windage is necessary, to allow of the shot being rammed home. The length of the bore should be such as to allow all the charge to be consumed before the shot leaves the gun, and to give the greatest initial velocity to the shot consistent with such lightness as is essential in order to work the guns. The lengths of guns in our service vary from about twelve to twenty calibres; all smooth-bored field guns being seventeen calibres long. 3. The exterior form of the gun should be such as to distribute the metal so as best to resist the strain of the gas, which is greatest at the breech, diminishing gradually towards the muzzle. All guns of recent construction are built on this principle, though the details may vary. The quantity of metal varies with the nature of the projectile and charge, and the service for which the gun is intended. The larger the calibre of the gun, the greater will be the strain exerted on the piece, because while the weight of the ball increases as the cube of its diameter, and the mass of the charge increases as the cube of the diameter of the bore, the surface acted on by the strain only increases as the square of the calibre, supposing the density of the shot to remain constant, and the charge to continue to bear the same relation to the weight of the shot. Ignorance of this principle has led many to think that success in a small gun or rifle argues equal success in a large piece of ordnance. Guns were formerly much ornamented externally; this practice, which actually weakened the metal, while increasing the expense, has now been abandoned. 4. In our service, a certain preponderance on the breech side of the trunnions has hitherto been given, to keep the gun steady on its carriage; but the Americans have done away with this, and apparently wisely, as a gun without preponderance is much more easily worked.

Until quite recently all guns in our service were cast, either iron or bronze. Now all, with few exceptions, are built up of wrought iron, or of steel barrels, with wrought iron outside.

Guns may be divided into breech-loaders and muzzle-loaders, smooth-bored and rifled. The above principles apply equally to all. The accompanying figure of an ordinary smooth-bored gun explains the shape and names of the chief parts. The *cascable* is from F to A;

first reinforce A to B; second reinforce B to C; chase C to D; muzzle D to E; cd is called the breech; G the trunnion.

GUN COTTON

The peculiarities of construction consequent upon guns being rifled, and the different systems of rifling, are explained in the article **RIFLED GUNS**. For the history of their invention, see **CANNON**; and for their employment in war, **ARTILLERY**. A table of the guns most commonly in use in our service is given in the article **ORDNANCE**. For further information, the reader is referred to Major Owen's *Lectures on Artillery*; and *Ency. Brit.* art. 'Gunmaking.'

Gun Cotton (Fr. *coton poudre*, Ger. *schiesswoll*). A highly explosive and inflammable substance, discovered in 1846 by Professor Schönbein, of Basle. As at present manufactured for military purposes, it is obtained by impregnating cotton in the form of thread, which has been thoroughly cleansed and dried, with a mixture of three parts of the strongest sulphuric acid and one part of the strongest nitric acid. The cotton is steeped in this for about forty-eight hours, and then whirled round in a centrifugal machine to remove the superfluous moisture. It is then immersed in cold water, and washed in a running stream till no acid is perceptible to the taste; it is now partly dried, and boiled for a few minutes in a weak solution of carbonate of potassa, and again restored to the stream for from fourteen to eighteen days; after which it is washed by hand and thoroughly dried. In these operations it is necessary to insure: 1. That the cotton be quite dry and pure before it is impregnated with acid; 2. That every particle be well saturated with acid; 3. That all free and superfluous acid be removed. The appearance of the cotton is not changed, but it weighs about seventy-seven per cent. more after these operations.

The skeins are now ready to be made up for use; and by the method in which the cotton is arranged, its explosive power can be regulated. Cartridges for cannon, where ignition should be gradual, are made up by winding the cotton round hollow cones of wood; bursting charges for shells, match lines, &c., by weaving the cotton into a hollow cylinder; small-arm cartridges in the same way, with layers of paper between the webs; for mining charges a hollow twisted rope is used.

The peculiar advantages of gun cotton for military and engineering purposes are: 1. The comparative absence of smoke and residuum or 'fouling matter': less heat is evolved also than by gunpowder; 2. One pound of gun cotton equals three pounds of gunpowder in propelling force, and, if the ranges are equal, the recoil of a gun fired with cotton is much less; 3. Though the explosion of gun cotton in open space has very little effect, its violence increases with confinement, so that while it may be used as match in the air, it possesses enormous power for blasting, mining, exploding shells, &c.; 4. While the manufacture of gunpowder is complicated and full of danger, that of gun cotton consists only of soaking and washing, and is free from risk.

The points which must be determined before

GUNBOAT

gun cotton can come into universal use, are: whether its qualities are permanent under ordinary care, and whether heat or damp produce loss of strength or dangerous decomposition. These questions have yet to be decided. As far as is known, gun cotton will explode at a temperature of 277° Fahr. (gunpowder not till 600° Fahr.); it must, however, be ascertained whether the heat of tropical climates will injure its quality. It can be exploded by percussion if placed between iron and iron, but only the portion actually struck takes fire. Gun cotton will absorb very little damp, and returns to its normal state on being restored to a dry place, whereas gunpowder is destroyed by wet. This property is of great value, as gun cotton may be buried or drowned, and made again fit for use by drying.

Soon after the invention of gun cotton, the Austrian government appointed a committee on the subject, to one of whom, baron von Lenk, the present success of the material is due. Some accidents, said to be owing to spontaneous explosion, caused its use to be discontinued in Austria. In England, in 1847, Messrs. Hall, of Faversham, commenced to make it; but an explosion caused the manufacture to be abandoned. Baron von Lenk's improvements having attracted notice, our government appointed a committee, which is now carrying on a series of elaborate experiments.

The chemical changes which take place in the cotton under the treatment above described, are not yet thoroughly understood; but it appears that in the gun cotton manufactured by Lenk and by Professor Abel at Waltham Abbey, three equivalents of hydrogen are replaced by hyponitric acid, the result being the formation of a material called *trinitro-cellulose*, and described by the formula $C_{36}H_{21}O_{30}.NO_4$. For further details respecting the manufacture and uses of gun cotton, see **PROXILINE**.

Gun Pendulum. In Gunnery, a rest for a gun, suspended on an axis so as to form a pendulum. When the gun is fired, this pendulum recoils through an arc which is measured, and so the velocity of the shot can be calculated. [**BALLISTIC PENDULUM**.]

Gun Tackle. A system of pulleys, consisting of two single blocks, one movable, the other fixed, the standing end of the fall being made fast to the movable block. It increases the power threefold.

Gun-room. In ships of war which have no ward-room, the gun-room is the common dining and dwelling cabin of all officers except the captain and midshipmen. In ships with a ward-room, the gun-room is inhabited by the junior officers only.

Gunboat. A small vessel carrying not more than four guns, most frequently only one, and of trifling draught of water. Steam gunboats, especially when iron plated, are most powerful auxiliaries to a fleet; their light draught enables them to approach the shore or ascend rivers; their heavy guns tell with deadly effect from their near positions; while

GUNNER

they themselves, from their diminutive size, can scarcely be hit.

Bombvessels differ from gunboats in being of greater beam or width to withstand the vertical recoil of the mortars which they carry. They are rarely propelled by steam.

Gunner. In the Artillery, corresponds to private in the Line. The appointment of *master gunner* is an ancient office under the crown; it is found in the time of Henry VIII. It is now filled by pensioned sergeants of artillery.

GUNNER. In the Navy, a warrant officer responsible for the safety of the powder magazine, and the proper care of the great guns.

Gunnery. A science which has for its object to ascertain the effects produced by firing a projectile from a piece of ordnance, under every variety of circumstances; and thus to determine the right form of gun and projectile, the best proportion of charge, the elevation to be given to the piece, and the quality and disposition of material best adapted to resist the action of projectiles at various ranges.

Before any experiments can be carried on to ascertain how various causes affect the flight of a projectile, its initial velocity, or the velocity which it has on leaving the muzzle of the gun, must be determined. This has been effected by various methods. The ballistic and gun pendulums [BALLISTIC PENDULUM; GUN PENDULUM] were until lately employed; but the more accurate results obtained by Major Navez' instrument [ELECTRO-BALLISTIC APPARATUS] have caused its adoption for this purpose. Experiments of the greatest value were carried on by Dr. Hutton, in the latter half of the eighteenth century, 1783-5, and are to be found in his *Tracts*. From these experiments he deduced the following practical conclusions, which later investigations have tended to confirm:—

1. The velocities generated by the action of

GUNNERY

different charges of powder, in the same gun, are nearly as the square roots of these charges.

2. The velocities generated by the same charge of powder from the same gun upon balls of different densities, will be inversely as the square roots of the weights.

3. The velocities generated by different charges of powder upon balls of different densities will be nearly in the ratio of the square roots of the charges, divided by the square roots of the weights of the balls.

4. The velocity of the ball increases with the charge to a certain point, which is peculiar to each gun, where it is greatest; and by further increasing the charge, the velocity gradually diminishes till the bore is quite full of powder.

5. The velocity continually increases as the gun is longer, though the increase of velocity is very small in respect of the increase in length, the velocities being in a ratio somewhat less than that of the square roots of the length of the bore, but somewhat greater than that of the cube roots of the length, and indeed nearly in the middle of the ratio between the two.

6. The range increases in a much less ratio than the velocity, and is nearly as the square root of the velocity, the gun and elevation being the same. Very little is gained in the range by a great increase in the length of the gun, the charge being the same; for the range is nearly as the fifth root of the length of the bore, an increase so small as to amount only to about one seventh part more range for a double length of gun.

7. The time of the ball's flight is nearly as the range, the gun and elevation being the same.

8. A great difference in the velocity arises from a small degree of windage.

The following table of initial velocities of a few service projectiles is deduced from experiments with Navez' electro-ballistic apparatus:

Nature of Ordnance	Charge	Projectile		Initial Velocity
		Nature	Weight	
Cast iron	10" gun, 87 cwt. . . .	Hollow shot . . .	lb. oz. 88 5	Feet per second 1,292

GUNNERY

The empirical formula used in our service for estimating the initial velocity of a projectile is

$$v = \frac{1600}{\sqrt{\frac{ac}{w}}}$$

where a = coefficient of windage (determined by experiment), c = the charge in lb., w = the weight in lb.

Knowing the initial velocity of a projectile, we can proceed to ascertain its velocity at any point of its flight, its trajectory, and its range; and for the sake of simplicity, we will first suppose its motion in a vacuum, where it is acted upon by two forces only, viz. the force of projection and the force of gravity. Suppose

a shot to be fired from a gun A B, in the direction A B C; if it were acted upon by the force of projection alone, it would continue to move in that direction with uniform velocity. But, the instant that the shot leaves the muzzle, it commences to fall by reason of gravity; and it falls in the first second of its flight sixteen feet, so that at the end of that time it has reached a point D, found by constructing a parallelogram, the sides of which represent the forces of projection and gravity respectively; and because the spaces through which a body falls by gravity are as the squares of the times, at the end of two seconds it has reached a point F, E F being equal to twice C D, at the end of three seconds a point H, G H being equal to three times C D, and so on, describing a parabolic curve B D F H. The properties of this curve being known, the trajectory, time of flight, &c., of a projectile fired in vacuo can be easily calculated, if the initial velocity is known; and since, as will be presently shown, the resistance of the atmosphere to a projectile fired with a very low initial velocity is very small, it may be practically disregarded for shells fired from mortars, and in that case the parabolic theory is found to give tolerably accurate results.

But the projectile fired under ordinary conditions from a gun, is acted upon by a third force, viz. the resistance of the atmosphere; and this so modifies the curve as to render the parabolic theory practically useless when a projectile is fired with a high velocity. Dr. Hutton's experiments showed that this resistance increases gradually up to a velocity of about 1,500 feet per second, when its ratio is to the velocity as the 2 153 power of the latter; but when the velocity exceeds this, the ratio again diminishes. Practically, however, for ordinary purposes of calculation, we may assume the resistance of the atmosphere to vary as the square of the velocity.

The nature of this resistance is explained by Dr. Hutton in his seventh tract. He considers that it 'is of a triple nature; one part of it being in consequence of the vis inertiae of the particles of air, which the ball strikes in its course; another part from the accumulation of the elastic air before the ball; and the third part from the continued pressure of the air on the fore part of the ball, when the velocity of this is such as to leave a vacuum behind it in its flight, either wholly or in part.' Tables of resistances to a two-inch ball, derived from experiment, were constructed by Dr. Hutton.

The resistance which a projectile meets in moving through the atmosphere depends not only on its velocity, but on the magnitude of the surface it presents to the resistance, and its peculiar form. With spherical shot, the resistance will be as the squares of the diameters, and, as already shown, as the squares of the velocities, or as $d^2 v^2$.

But the retardation of a projectile, or its loss of velocity in consequence of this resistance, must not be confounded with the resistance itself. This retardation, while it is as the resistance, is inversely as the weight of a projectile. With a spherical shot, therefore, the weight being proportional to the cube of the diameter, the retardation will be as

$$\frac{d^2 v^2}{d^3};$$

consequently the greater the diameter of the ball, the less the retardation, where the initial velocities are equal.

If an elongated projectile and a ball of equal weight be fired with the same initial velocity, the former will be less retarded than the latter, because its diameter is less than that of the ball. Hence the more an elongated projectile is lengthened without altering its weight, the less will it be retarded, because its diameter will be reduced; and it is because elongated projectiles offer so much less resistance to the air than round shot of the same weight that their velocities are retained so much longer, and consequently that their range is so much increased.

The following comparison, deduced from actual practice, will show to how great an extent this is the case:—

Projectile	Range	Time of Flight	Initial Velocity	Mean Velocity	Final Velocity
	yds.	seconds	ft. per second	ft. per second	ft. per second
40-lb. segment shell (elongated).	2000	6.25	1164	960	756
68-lb. solid shot (ball)	2000	6.25	1579	980	341

The form of projectile which experiences the least resistance from the atmosphere has been the subject of many experiments, and it appears indisputably established that the shape of the hinder part is of some importance. The ogival form of head is probably the best. [PROJECTILE.]

GUNNERY

The *final or remaining* velocity of a projectile is its velocity at any given point of its range ; and varies, of course, with its retardation. Dr. Hutton established formulæ by which this might be calculated for spherical shot, and General Didion of the French army has established a formula equally applicable to elongated shot. Lieut. Noble, R.A., has lately constructed tables applying these formulæ to the Armstrong service shot. The following table will show some velocities of Armstrong service shot, at a range of 1,000 yards, determined by the electro-ballistic apparatus :—

Gun	Charge	Projec- tile	Velocities at		Velocity lost in 900 yards
			40 yds.	1000 yds.	
Rifled B.L.	7-inch	12	111	971	141
	7-inch	12	104	1144	147
	40-pr.	5	41½	1199	185
	20-pr.	2½	20½	1153	176
	12-pr.	1½	11½	1241	255

The penetration of a projectile depends to a great extent upon its velocity at the moment of impact, its weight and form, the material of which it is made, &c. At the moment of impact there is stored up in the projectile an amount of accumulated work, which causes to vibrate, penetrates, or fractures, the object struck ; and which also tends to destroy the projectile. The penetration, however, must not be confounded with the work or momentum.

Elongated (Armstrong)			
Nature of Projectile	Weight	Charge	Penetration
	lb.	lb.	ft. in.
7-inch shell . .	100	9	3 8
6-inch shot . .	82	10	7 6
6-inch shell . .	77	9	4 3
40-pr. shot . .	41	5	4 1
40-pr. shell . .			

The application of gunnery depends upon the above principles, and on others which cannot be noticed within the limits of this article. It is evident that in order to cause a shot to strike an object at a distance, the axis of the gun must be directed upon a point above the object aimed at, but in the same vertical plane. The charges for various guns being determined, experiments have shown the various elevations necessary to obtain various ranges, and tables have been constructed from these. In order to *lay* a gun correctly, the gun is provided with sights.

A line A B drawn from the highest point of the base ring A to the highest point of the

muzzle B (when the trunnions are horizontal), is called the *line of metal*, and notches are cut
VOL. II. 81

A battering ram and a shot may have equal momentum ; the shot will penetrate a wall, doing little damage beyond its own immediate vicinity ; the ram will cause a large portion of the wall to vibrate, without penetrating. If two projectiles of the same form be fired with equal initial velocities at the same range into the same resisting material, their penetrations are as their diameters and densities, and the squares of their velocities ; thus, the greater the diameter and density, the greater will be the penetration. When shot of the same density are fired into the same material, their penetrations vary as their diameters and the squares of their velocities.

From this it is evident that great velocity is the most necessary element of penetration, and that the American plan of firing heavy shot with low velocities is not good for penetration : for instance, if two spherical shot strike an object, one of ten inches diameter with a velocity of 1,200 feet per second, the other of six inches diameter with a velocity of 1,600 feet per second, the penetration of the larger shot to the smaller will be as $10 \times 1,200 \times 1,200 : 6 \times 1,600 \times 1,600$; or as 14·4 : 17·9.

For the form and material of projectile best adapted for penetrating purposes, see PROJECTILE.

The following table of penetrations will show what was done at Eastbourne against a martello tower, best brickwork, range 1,032 yards :—

Spherical			
Nature of Projectile	Weight	Charge	Penetration
	lb.	lb.	ft. in.
68-pr. shot . .	68	16	1 8
68-pr. shell . .	51	16	1 9
32-pr. shot . .	32	10	1 4
32-pr. shell . .	28½	10	1 4

in the gun at those two points. Now if the line of metal be directed to the object, that line will necessarily be in the same vertical plane with the object ; but by reason of the conical shape of the gun, the line of metal has an inclination to the axis, and consequently if these two points are brought into line with the object, the axis of the gun will point above it. This inclination of the line of metal to the axis of the bore is called the *line of metal elevation*, and varies from 1° in light field guns, to 2¼° in Monk's guns.

To allow the gun to be laid *point blank*, and at elevations less than the line of metal elevation, a *dispart sight* C is placed on the gun, the head of which forms with the notch on the base ring a line A C, parallel to the axis of the bore ; so if these two sights are directed on an object, the axis of the gun is also pointed at it, but some few inches below. Now, this dispart sight being fixed, a tangent scale, of which the

GUNNEY

head is made (when down) to correspond with the notch in the base ring, is attached to the gun at the breech, and can be raised and fixed at any required height. It is graduated with degrees corresponding to the radius from the head of the dispart sight, so that if it be necessary to give a gun 3° , or any other required amount of elevation, it is only necessary to raise the tangent scale to that amount, when the line of sight will be inclined at the required angle to the axis of the bore. This method of sighting is adopted with various modifications for all kinds of guns.

Although of late years much attention has been directed to the problems of gunnery, the great expense attendant upon practical experiments forbids private investigation. A systematic course of experiments is very much required, in which the one object should be to determine certain laws, which as yet are but imperfectly defined.

See **ARTILLERY**; **CANNON**; **GUN**; **ORDNANCE**; **PROJECTILE**; **RIFLED ARMS**; and the following, which are among the chief works on Gunnery: Robin's *Mathematical Tracts*; Hutton's *Tracts*; Sir Howard Douglas' *Naval Gunnery*; Boxer's *Treatise on Artillery*; Owen's *Lectures on Artillery*, from which the tables in this article are taken by permission; Paixhaus' *Force et Faiblesse de la France*; Didion's *Traité de Ballistique*; Piobert's *Traité d'Artillerie* and *Cours d'Artillerie*.

Gunney (Bengal.). A coarse sackcloth made in Bengal of the fibres of two species of *corchoron*. Rice, saltpetre, pepper, and other articles exported from Calcutta are packed in bags or sacks made of this material; they also form a considerable article of exportation.

Gunpowder. An intimate mixture of saltpetre, sulphur, and charcoal, the proportions in the powder made for the English government being about 75 parts saltpetre, 10 sulphur, 15 charcoal. The ingredients, which should be quite pure, are weighed out, pulverised, mixed, incorporated under rollers, pressed (50 to 70 tons on the square foot), granulated, dusted, glazed by friction, dried, and the powder thus made is packed in barrels.

The value of gunpowder consists in its containing stored up in small space substances which, on the temperature of the least portion of them being raised to about 700° Fahr., suddenly expand with great force, developing at the same time so much heat as to augment in a high degree the elasticity of the gases produced. Gunpowder is easily manufactured, has no tendency to spontaneous combustion, does not absorb moisture readily, and by the alteration of the size of the grains, and of the pressure to which it is subjected in manufacture, can be made to develop its force in greater or less time as may be required.

The absolute force of gunpowder has never yet been accurately determined; but as much attention has been given lately to the subject, and the means of obtaining accurate results from experiments are increasing, we may hope

GUNTER'S LINE

soon to have the point settled. The principal gases evolved on combustion have hitherto been supposed to be carbonic acid, carbonic oxide, nitrogen, &c.; but even this point has been much contested; and it has been lately shown by M. Melsus that at a very high temperature two volumes of carbonic acid may become three volumes of carbonic oxide and oxygen, similar changes taking place in the other products.

The history of the invention of gunpowder is involved in obscurity, and must remain so until some contemporary voucher can be produced. It was not used in Europe as an agent in warfare, till about 1320-1330. [**CANNON**.]

Gunpowder Plot. In English History, the celebrated conspiracy of certain disappointed Roman Catholics to destroy the king, James I., and the two houses of parliament, by gunpowder, which was detected on the fourth of November, 1605. The story which affirms that by extraordinary sagacity King James detected the nature of the plot from the mysterious letter sent to Lord Monteagle, seems now to have lost all credit. It had long been remarked that Salisbury and Carlisle (probably before the scheme between themselves and their royal master was concerted) had claimed for *themselves* the credit of the discovery; and it now appears that Lord Monteagle had been previously rewarded by government for mysterious services, apparently rendered in the capacity of spy: so that it is highly probable that he was acquainted with the design of the malcontents, and that the celebrated letter was an invention, destined to conceal the real mode of discovery. Those who are anxious to study the Roman Catholic version of the story will find it ably detailed in the pages of Lingard (vol. vii. ch. 1. 4to ed.). That writer seeks to throw the whole onus of the conspiracy on Catesby, its chief promoter, and to exculpate Father Garnet; Mr. Jardine (in his *State Trials*) is of a different opinion.

Gunter's Chain. The chain commonly used for measuring land. It is 66 feet or 4 poles in length, and consists of 100 links, each of which is joined to the adjacent one by three rings; the length of each link, including the connecting rings, is 7.92 inches. The advantage of this measure consists in the facility which it affords for numerical calculations. The English acre contains 4,840 square yards, and Gunter's chain being 22 yards in length, the square of which is 484, it follows that a square chain is exactly the tenth part of an acre. A square chain, again, contains 10,000 square links, so that 100,000 square links are equal to an acre; consequently the area of a field being estimated in square links, it is only necessary to divide the result by 100,000, or to cut off the last five figures, to obtain the

Gunter's Line. A logarithmic line engraved on scales, sectors, &c., serving to perform the multiplication and division of numbers instrumentally, as a table of logarithms does arith-

GUNTER'S QUADRANT

metically. The numbers are usually drawn on two separate rulers sliding against each other. In rough calculations this line affords considerable facilities.

Gunter's Quadrant. A quadrant of a peculiar kind adapted to the problems of finding the hour of the day, the sun's azimuth, and other common problems of the sphere.

Gunter's Scale. A large plane scale having various lines of numbers engraved on it, by means of which questions in navigation are resolved with the aid of a pair of compasses. It is usually called the *Gunter* by seamen. On one side of the scale the natural lines (as the line of chords, the line of sines, tangents, rhombs, &c.) are placed, on the other the corresponding logarithmic ones.

Gunwale. Means, generally, the upper part of the side of a vessel or boat.

Gurgoyle (Fr. gargouille, a water-shoot). In Gothic Architecture, the water from the roofs of buildings was commonly made to pass through the mouth of figures shaped like animals. These figures were sometimes ingeniously employed during the middle ages as vehicles for satire; and, like the carvings under the seats of stalls, illustrate the feuds of the secular and regular clergy, &c. They also served as images of evil spirits, put to base uses outside the church.

Gurhoffite. A compact magnesian carbonate of lime, from Gurhoff in Lower Austria.

Gurnard or Gurnet. [TRIGLA.]

Gutta Percha. This important article, the uses of which in arts and manufactures are rapidly increasing, is the produce of a large forest tree (*Isonandra Gutta*, Nat. Ord. *Sapotaceæ*) growing in the mountains of Singapore, and in the forests of Johore at the extremity of the Malayan Peninsula, and in Borneo; it is plentiful at Sarawak, where it is called *Niato*; it is also supposed to abound on the clusters of islands to the south of Singapore. The gutta percha appears to separate from the juice or sap of the tree in the same way as India-rubber, and its general properties in regard to solvents and to the products of destructive distillation resemble those of caoutchouc. At common temperature gutta percha is somewhat hard and very tough and unyielding; but when immersed in boiling water it softens so as to admit of being beaten into a mass and moulded into any requisite shape, and on cooling it resumes its hardness. In very thin films it has a pale yellow or pinkish tinge, but generally occurs in brown or blackish lumps or masses, of a somewhat mottled appearance upon the cut surface, and translucent at the edges. When softened it may be stretched into slips which do not recover their former shape when the force is withdrawn, but retain a kind of leathery pliability on cooling. When heated to about 350° gutta percha undergoes a kind of fusion, and remains viscid when cold. It burns with a yellow smoky flame. It is said to be obtainable in very large quantities, but that from

GYMNASIUM

the destructive mode hitherto pursued by the natives in obtaining it, there is a risk of its scarcity. It was first made known in England in 1843 by a communication from Dr. Montgomery to the Society of Arts.

Gutta percha has been applied to the manufacture of cements, architectural and other ornaments, bookbinding, tubes, water-pipes, engine-hose, picture-frames, bottles, and drinking cups, and to the soles of boots and shoes, &c. &c. When blended with caoutchouc, it is used for a variety of other purposes. It becomes highly electrical by friction.

Gutta Serena (Lat.). [AMAUROSIS.]

Guttæ. In Architecture. [DROPS.]

Guttiferæ (Lat. gutta, a drop, and fero, I bear). A natural order of hypogynous Exogens, typical of the Guttiferal alliance, and often called *Clusiaceæ*. In that alliance they are distinguished by their simple opposite leaves, without stipules, their symmetrical flowers with equal-sided petals and adnate beakless anthers, their sessile radiating stigmas, and their solitary or few seeds. Lindley associates them with *Hypericaceæ* and *Ternstroemiaceæ*. The order contains some plants of great utility.

Guttur (Lat. a throat). In Mammalogy, is applied to the whole under surface of the neck.

Gutturals (Lat. guttur). Letters pronounced by a peculiar effort of the throat. There are no gutturals properly so called in the English language, although the guttural sound may often be heard in some provincial pronunciations of the letter *r*. Nor are there in the pure French or Italian, although they are frequent in the dialects: e. g. the letter *c* hard (as in *casa*) has in the Tuscan a strong guttural sound. In the Spanish language alone, of those derived from the Latin, gutturals are common. In German, the guttural *ch* is largely used. In the Celtic languages, *gh* and *ch* are also sounded with much variety of guttural intonation.

Guy. A rope used to swing any weight, or to keep steady any heavy body and prevent it from swinging while being hoisted or lowered; also the tackle by which any fore-and-aft sail is held forward to prevent it gybing.

Gybing. In Sailing, the act of going about when the wind is astern or abaft the beam. It consists in bringing the ship's head across the wind, when the wind exercises its force on the opposite side of the sail to that which it previously affected.

Gyle. A large vat or cistern. The *liquorgyle* in a brewery is the water-cistern or vat.

Gymnasiarch (Gr. γυμνασιάρχος). An officer who had the charge of the gymnasium and of all matters relating to them. This was one of the offices which at Athens were called **LITURGIES** [which see].

Gymnasium (Lat.; Gr. γυμνασιον). Originally a space measured out and covered with sand for the exercise of athletic games. Afterwards, among the Greeks, the gymnasium became spacious buildings or institutions for the mental as well as corporeal instruction of youth. They

were first built at Lacedæmon, whence they spread through the rest of Greece, &c. into Italy. They did not consist of single edifices, but comprised several buildings and porticoes, used for study and discourse, for baths, anointing rooms, palæstras in which the exercises took place, and for other purposes. Two of the Athenian gymnasia, viz. the Lyceum and Academy, were rendered famous by being the scenes of the lectures of Aristotle and Plato respectively.

The term *gymnasium* has descended to modern times. In Germany the higher schools, intended to give immediate preparation for the universities, are termed *gymnasia*. In Prussia the scholars undergo examination on leaving them: their compositions at this examination are sent to the minister of instruction and ecclesiastical affairs; and they receive testimonials of fitness, No. 1, No. 2, or No. 3, according to their degree of proficiency. Persons who have fitted themselves for the universities without passing through the gymnasia are examined by a committee appointed by government, which sits half-yearly for the purpose.

Gymnastics (Gr. *γυμναστική*). Under this name were comprised by the ancients all those games and exercises which were performed with the body partly naked (*γυμνός*); such as wrestling, boxing, running, throwing the quoit, playing at ball, &c. They were first instituted at Lacedæmon, where they were not confined to men, but were also considered a necessary part of the education of females. In the rest of Greece, where they subsequently spread, they were also held of the highest importance, and as such were conducted under the superintendence of the government, and entered conspicuously into the political schemes of the philosophers. In this respect the Greeks offered a remarkable contrast to their Asiatic neighbours, among whom it was considered a great disgrace even for a man to be seen naked. At Rome gymnastics were principally exercised by the mercenary athletes.

Gymnodontes (Gr. *γυμνός*, *naked*; *ὀδούς*, *a tooth*). The name of the family of Plectognathic fishes comprehending those which have the jaws protruding, and covered with a more or less complex layer of dense ivory substance serving the office of teeth.

Gymnogens. A name proposed by Lindley for the naked-seeded plants referred to the orders *Conifera*, *Taxacea*, *Gnetacea*, and *Cycadacea*. In these plants there is no proper ovary, but the seeds are fertilised by the pollen coming in direct contact with the foramen of the ovule. They are also called *Gymnosperms*; that is, literally, *naked-seeded plants*. Gymnogens are largely represented amongst fossils.

Gymnosophists (Gr. *γυμνοσόφισταί*, *naked philosophers*). A sect of Indian philosophers who lived naked in the woods, and submitted to other strange austerities. They believed in the immortality and transmigration of the soul, and enjoyed great reputation for astronomical and physical science.

There was likewise an African sect of philosophers bearing the same name, who are said to have lived in Æthiopia, near the sources of the Nile, whose habits differed from those of the Indian sect, inasmuch as they lived as anchorites, while the latter congregated in societies.

Gymnospermia (Gr. *γυμνός*, and *σπέρμα*, *a seed*). An order of the Linnæan class *Didynamia*, in which the fruit consists of a few nut-like carpels surrounded by the calyx, instead of being enclosed in a capsule, as in the rest of the order. The *Labiata* are illustrations, but such seeds are not strictly naked.

Gymnotus, or rather **Gymnomotus** (a word coined from Gr. *γυμνός*, *naked*, and *νῆτος*, *the back*). The name of the genus of electric eels which are found in the fresh waters of South America: they have a median fin extended along the belly, but none on the back. Although to all outward appearance the gymnotus is nearly allied to the eel, yet, were that part of the body cut off which contains the nutrient, respiratory, and generative organs—all the parts, in fact, which are essential to the existence of the gymnotus as a mere fish—it would present a short and thick-bodied form, very different from that of the eel. The long electric organs are tacked on, as it were, behind the true fish, and thus give the gymnotus its anguilliform body. The backbone and muscles are of course coextended with the electric organs for their support and motion; and the air-bladder is continued along the produced electrophorus trunk, to give it convenient specific levity. Two long dorsal nerves are continued from the fifth and eighth cerebral nerves for ordinary sensation and motion. The spinal chord is continued along the vertebral column, for the exclusive supply of the electrical organs. These organs are four in number; two very large above, and two small ones below. The electricity discharged from them decomposes chemical compounds, produces the spark, and magnetises iron, as does that of the torpedo. But the magnetising power seems to be relatively weaker, while the benumbing shock communicated to other animals is stronger than in any other electric fish.

Gyn. In Artillery, a machine for mounting and dismounting ordnance from their carriages, &c. There are triangle and Gibraltar gyns in our service. [DERRICK.]

Gyn Tackle. A system of pulleys consisting of a double and triple block, the standing end of the fall being made fast to the double block, which is movable. It increases the power fivefold.

Gynæceum (Gr. *γυναῖκειον*). In ancient Greek Architecture, the portion of a dwelling or a public building set apart for the occupation, or for the exclusive use, of the female sex.

GYNÆCEUM. In Botany, a term invented by Røper to denote that organ commonly called the *pistil*: it may be understood to signify the female apparatus in plants.

Gynæocracy (Gr. *γυναῖκοκρατία*). A term sometimes used to indicate that state in which women are legally permitted to assume

the reins of government. It is used by way of contradistinction to the *Salic law*, which precludes them from the privilege of sovereignty. There are only five states in Europe to which the operation of the *Salic law* does not extend—England, Russia, Spain, Portugal, and Denmark.

Gynæconomi or **Gynæcoosmi** (Gr. γυναικονόμοι, γυναικοκόσμοι). Athenian officers, who seem to have acted as a sort of police in repressing excesses whether committed by men or women. But the time of their institution and the precise nature of their duties are not clearly ascertained.

Gynandria (Gr. γυνή, and ἀνὴρ, a male). The name of one of the classes in the sexual system of Linnæus. Its character is to have the stamens, style, and stigma consolidated into a body, called a *column*. The class chiefly consists of the plants now named *Orchidaceæ*.

Gynandrous. In Botany, plants of which the structure is referred to the Linnæan class *Gynandria*; i.e. which have the stamens, style, and stigma consolidated into one common body, called the *column*.

Gynobase (Gr. γυνή, and βᾶσις, a base). In Botany, the growing point inserted between the base of carpels in a conical manner, so as to throw them into oblique position. Such carpels are *gynobasic*; they have basilar styles which are enlarged and cohere in the centre. The Borage is an example of this structure.

Gynophore (Gr. γυνή, and φέρω, I bear). In Botany, the stalk sometimes developed at the base of the ovary within the calyx, as in the Passion-flower and the Caper-tree.

Gynostemium (Gr. γυνή, and στήμων, a stamen). A term invented by Richard to denote the column of an *Orchidaceous* plant. It is a combination of a filament and a style.

Gypogeranus (Gr. γύψ, a vulture, and γέρανος, a crane). The name was invented by Illiger for a most singular genus of Accipitrine birds, in which the structure of the bird of prey is modified by a lengthening of the legs and neck to adapt the species to combat with and destroy the most poisonous of the serpent tribe. The instincts of the gypogeranus, or secretary bird, as it is termed, correspond with its structure, and it preys principally on serpents; not refusing, however, lizards, or even insects. The bill is shorter than the head, curved nearly from its base, not toothed; the wings are armed with a short, strong, and obtuse spur; the feathers are continued down the long tibia to the tarsal joint, covering the front but not the back part of it; the toes are short, but strong; the anterior ones united by a membrane at the base. Species of the secretary vulture inhabit the Cape, the Gambia coast, and the Philippine Islands. The Cape secretary (*Gypogeranus serpentarius*) lives in pairs, builds on high trees, and runs with considerable swiftness.

Gypsies. The history of this strange nation of vagrants has been illustrated by the labours of several German writers, particularly Grellman (*Historical Inquiry respecting the Gypsies*,

translated into English by Raper, 1787) and Bischoff (*German and Gypsy Dictionary*). Their English name is said to be a corruption of the word *Egyptian*: the French call them *Bohemians*; but the names by which they are most widely known throughout Europe are, the German *Zigeuner*, Russian *Tzigan*, Italian *Zingaro*, Spanish *Gitano*, Turkish *Chinganeh*—all apparently varieties of the same distinctive appellation. Their origin has long been a subject of curious but unsuccessful antiquarian research. In Western Europe, they made their first appearance early in the fifteenth century, under a leader who styled himself the Duke of Lower Egypt: fortune-telling and thieving were then, as now, their predominant occupations. They were at that time treated as heathens and sorcerers, and the most severe laws were repeatedly enacted against them. At present they are found not in Europe only, but in Asia Minor, Egypt, Turkey, &c., forming everywhere a distinct race. In Germany, as well as England, they profess various trades, as itinerant horsedecalers, smiths, farriers, &c.; but they have never been reclaimed in any number to settled occupations. In England their most ordinary haunts are in the midland and southern counties, whither they are invited by the abundance of green lanes, downs, forests, or chases. They possess a language of their own; and are apparently destitute of religion, although in most countries professing that of the people among whom they dwell. (Marsden *On the Language of the Gypsies*; Hoyland's *Hist. Survvy*, 1816; *Quart. Rev.* vol. lv.; Borrow's *Account of the Gypsies of Spain*.)

The ancient severe statutes against these people have been repealed, and they are now only punishable as vagrants by the 5 Geo. IV. c. 83 s. 4, amended by 1 & 2 Vict. c. 38.

Gypsum. This is one of the many synonyms of native *sulphate of lime*. The varieties of it will be found described under their respective names, such as *Selenite*, *Satin Spar*, and *Alabaster*. As a *rock*, it is less common than most other substances that form distinct rock-masses, and is generally associated with marls and with rock-salt. It is sometimes applied as a top-dressing to clover and leguminous crops, but has lately fallen into disuse.

Gyrate (Lat. gyratus). In Botany, a term applied to bodies which are curled inwards like a crozier, as the young undeveloped fronds of Ferns.

Gyration (Lat. gyrus, Gr. γῦρος, a circle). In Mechanics, this term is synonymous with *rotation*. In combination with other words, however, the term gives rise to several technical expressions which require a brief explanation. A *centre of gyration* is a point within a body such that if the whole mass were concentrated therein, the moment of inertia with respect to the corresponding *axis of gyration* would remain unaltered. The circle described by such a point is called a *circle of gyration*, its radius the *radius of gyration*. Culling the latter *x* and denoting by *d* in the

GYRATION, ELLIPSOID OF

mass of any element at the distance r from the axis, then M being the total mass of the body equal to $\int dm$, we have $Mx^2 = \int r^2 dm$, where the integration is to be extended to all points of the body. The *principal radii of gyration* of a body with respect to any point are the radii of gyration with reference to the three principal axes through that point. An ellipsoid whose axes coincide in direction with those of the principal axes, and in magnitude with the corresponding radii of gyration, is called the *ellipsoid of gyration*.

Gyration, Ellipsoid of. [INERTIA, MOMENT OF; PRINCIPAL AXES.]

Gyrancephala (Gr. *γῦρος*, and *ἐγκέφαλος*, brain). A sub-class of *Mammalia*, consisting of those orders in which the superficies of the cerebrum is folded into gyri or convolutions, while the hinder lobes project over more or less of the cerebellum, and the olfactory lobes are covered. Those traces of affinity to the Oviparous sub-kingdom which the *Lycencephala* and *Lussencephala* present are absent in these animals. With the exception of the Elephants, the blood from the head and anterior limbs is returned to the right auricle by a single prececal trunk. The orders *Quadrumanæ*, *Carnivora*, *Artiodactyla*, *Perissodactyla*, *Proboscidea*, *Taxodonta*, *Sirenia*, and *Citacea*, belong to this sub-class. The mammalian modification of the vertebrate type attains its highest physical perfections in

IIABEAS CORPUS

the *Gyrancephala* as manifested by the bulk of some, by the destructive mastery of others, by the address and agility of a third order; and through the superior psychological faculties which are associated with the higher development of the brain, the *Gyrancephala* afford those species which have ever formed companions and servitors, and valuable sources of wealth and power, to mankind.

Gyrfalcon. [JERFALCON.]

Gyri (Lat.; Gr. *γῦρος*). In Mammalogy, the annular series of scales in the tails of certain quadrupeds.

Gyrinus (Lat.; Gr. *γύρινος*, a tadpole). The water flea.

Gyrodon. A fossil fish of the family of *Pycnodonts*. It occurs in the oolite of Baden.

Gyrogonites (Gr. *γῦρος*, and *γόνος*, seed). Bodies found in fresh-water deposits; originally mistaken for small shells, but afterwards ascertained to be the seed-vessels of plants of the genus *Chara*.

Gyroscope (Gr. *γῦρος*, and *σκοπέω*, I look). An instrument for illustrating the composition and resolution of rotations. It consists essentially of a disc which rotates around the diameter of a ring which itself rotates around the diameter of a second ring.

Gyrose (Lat. *gyrus*, a circle). In Botany, a term applied to bodies which are bent backwards and forwards, like the anthers in Cucurbitaceous plants.

H

H. An aspirate of the guttural kind, used in most modern and ancient languages. The claims of *h* to be regarded as a letter have been denied by many grammarians; and certainly, when it is remembered that the sound of this letter is produced by a mere emission of the breath, without any conformation of the organs of speech, this opinion would seem well founded. There are others, however, who insist that there is no feature in the sound or qualities of this letter which it does not possess in common with some other consonants, and, consequently, any attempt to invalidate its claim to the distinction, militates equally against them. The figure H was used by the Greeks to signify the aspirate, until about the fifth century before Christ. After that time it was gradually abandoned in Greek writing, while its use was still preserved by the Latins. In the former language it was superseded by the small mark called the *spiritus asper* (´), which was placed above the letter to which the aspirated sound was to be given. In many Latin words the letter *s* represents the Greek aspirate, as *sub* for *ὑπό*, *sal* for *ἅλς*, *ser* for *ἔξ*, *septem* for *ἑπτά*, *serpo* for *ἐρπω*, &c. As an abbreviation, *h*

was used by the Latins for *homo*, *hæres*, and *hora*; and as a numeral it expressed 200.

H. In Music, the designation given by the Germans to the note B♭; their B being equivalent to the English Bb.

Habeas Corpus (Lat.). In Law, the title of a writ, of which there are several kinds. *Habias corpus ad respondendum* is to remove a prisoner, confined by the process of an inferior court, in order to charge him with a new action in a court above. *Habeas corpus ad subjiciendum* is a high prerogative writ, directed to a person detaining another, and commanding him to produce the body of the prisoner. This is the writ which, by stat. 31 Ch. II. c. 2, must be granted on application of any party committed and charged with any crime except treason or felony; or, if charged with those crimes, having been acquitted or not tried on the second term or session after his commitment. It had been held that this writ issued from the superior courts in England to all the foreign dependencies of the crown; but by 25 & 26 Vict. c. 20 this power is abolished as to colonies having courts able to issue the writ.

HABERE FACIAS POSSESSIONEM

Habere Facias Possessionem (Lat.). In Law, a judicial writ, sued out by the successful plaintiff in an action of ejectment, as a direction to the sheriff to cause him to have possession of the land and premises recovered; and this the sheriff is bound to execute, breaking open doors, or summoning the posse comitatus, if necessary.

Haubergeon (Fr. haubergeon). A small short hauberk. [HAUBERK.]

Habzella. The plants now referred to this genus of *Anonaceæ* were formerly placed in *Xylopiæ*, and are by many retained there. *H. æthiopica*, the Ethiopian Pepper, is a tall shrub, with egg-shaped leaves, downy beneath, and bearing pod-like carpels, which are dried and used instead of pepper. Other species possess similar pungent and aromatic properties.

Hack. A name given to the rows of crude bricks, as they are exposed in the field to dry.

Hackle. A board set with sharp iron spikes for combing or pulling out hemp.

Hackles. A term applied to the slender feathers, from the necks and backs of birds, used by fly-fishers. The most esteemed hackles are the *duns*.

Hackney Coaches (Fr. coche-a-haquenée, from haquenée, a horse formerly let out on hire for short journeys). Vehicles for hire were first introduced in France in 1650 [FIACRE]; in England a few years earlier, and in Edinburgh in 1673.

Haddock. This fish, *Morhua Æglefinus*, is found in the Northern Ocean, but does not enter the Baltic. It makes its annual appearance on the Yorkshire coast in December, in a vast shoal extending from Flamborough Head to the mouth of the Tyne.

Hades (Gr. ᾍδης, also Ἅιδης). In Greek Mythology, a word denoting the abode of the dead, or the god of the nether world, called also Pluto. The origin of the name is doubtful. According to Hesiod, the mortals of the brazen age were the first who descended to Hades.

Hading. In Mining, the direction of a slip or *fault*. The deviation from the vertical of a mineral vein is called its *hade*.

Hadj (Arab.). The Mohammedan pilgrimage to Mecca and Medina: whence Hadji, a pilgrim, or one who has performed this pilgrimage; Hedjaz, the holy land, where these cities are situated. The most complete and authentic description of it is that of Burckhardt, who performed it, in the guise of a Mohammedan, in 1814. It is fixed to a particular lunar month, and consequently takes place in every season of the year. It was a custom long anterior to the establishment of Islamism, the famous 'black stone' of the Caaba at Mecca being then the object of veneration. Every year a black silk stuff is now sent by the sultan to cover the Caaba. There are usually five or six caravans; from Syria, Egypt, Barbary, the East, and the North. In 1814, the number of pilgrims was about 70,000, and this was considered small. The pilgrims go through several ceremonies at Mecca, of which the principal

HÆMATOCRYA

are the *tawaf*, or procession round the Caaba, and drinking of the well Zemzem; they then proceed to the summit of the hill Al Akaba; and lastly to Medina, the place of the prophet's burial. (Burckhardt's *Travels in Arabia*, 1829; *Quart. Rev.* vol. xlii.: see also the travels of Captain Burton, who succeeded in visiting the holy city in disguise.)

Hæmachrome (Gr. αἷμα, blood, and χρώμα, colour). The colouring matter of the blood: called also *hæmatosyn*.

Hæmacrymes (Gr. αἷμα, and κρυός, cold). A name by which Latreille designates the animals with cold blood.

Hæmal Arch (Gr. αἷμα). That part of the vertebra or primary segment of the skeleton which encompasses the main axis, or its prolongations, of the vascular system. It is situated opposite the neural arch, and, except in man, is inverted and beneath the centrum.

Hæmapophysis (Gr. αἷμα, and ἀπόφυσις, process). The autogenous vertebral elements which close or form the hæmal arch. In the human thorax they close the arch, as *cartilages of the ribs*, with the aid of a hæmal spine or sternal bone; in the Saurian tail they form, with the spine, the entire hæmal arch.

Hæmatemesis (Gr. αἷμα, blood, and ἔμεσις, vomiting). Vomiting of blood from the stomach, generally preceded by weight and uneasiness about the region of the stomach, and unaccompanied by cough and the other symptoms of *hæmoptysis*.

Hæmathermes (Gr. αἷμα, and θερμή, heat). The name given by Latreille to the animals with warm blood.

Hæmatics. Medicines presumed to act especially upon the composition of the blood.

Hæmatine (Gr. αἷμα). The colouring principle of Logwood.

Hæmatinics. Medicines which tend to increase the proportion of the colouring globules of the blood. Certain preparations of iron are supposed to belong especially to this class.

Hæmatite. Native oxide of iron: its streak and powder are blood-red. It occurs in Cumberland, where it is used in the manufacture of steel.

Hæmatocœle (Gr. αἷμα, and κῆλη, a tumour). A tumour arising from extravasated blood.

Hæmatocrya (Gr. αἷμα, blood; and κρυός, cold). This class has been proposed by Professor Owen to include the groups of animals commonly termed *fishes* and *reptiles*. 'The conformity of pattern in the arrangement of the bones of the outwardly well-ossified skull in certain fishes with well-developed lung-like air-bladders, e.g. *Polypterus*, *Lepidosteus*, *Sturio*, and in the extinct reptiles *Archegosaurus* and *Labyrinthodon*; the persistence of the notochord (*chorda dorsalis*) in *Archegosaurus*, as in *Sturio*; the persistence of the notochord and bronchial arches in *Archegosaurus* and *Lepidosiren*; the absence of occipital condyle or condyles in *Archegosaurus*, as in *Lepidosiren*; the presence of teeth with the labyrinthine interblending of dental tissues in *Dendrodus*, *Lepidosteus*, and

HÆMATOCRYA

Archegosaurus, as in Labyrinthodon; the large median and lateral throat-plates in Archegosaurus, as in Megalichthys, and in the modern fishes *Arapaima* and *Lepidosteus*; all these characters point to one great natural group, remarkable for the extensive gradations of development linking and blending together piscine and reptilian characters within the limits of such group. The salamandroid (or so-called *sauroid*) Ganoids, e.g. *Lepidosteus* and *Polypterus*, are the most ichthyoid, the Labyrinthodonts are the most sauroid, of this annectant group; the Lepidosiren and Archegosaurus are intermediate gradations, one having more of the piscine, the other more of the reptilian character. Archegosaurus conducts the march of development from the fish proper to the labyrinthodont type; Lepidosiren conducts it to the perennibranchiate or modern batrachian type. Both forms expose the artificiality of the ordinary class distinction between Pisces and Reptilia, and illustrate the naturalness of the wider class of cold-blooded vertebrates, which I have called *Hæmatocrya*. The correlative group of warm-blood animals is termed *Hæmatotherma*. Professor Owen is 'unable to define any adequate boundary for dividing cold-blooded air-breathing vertebrates into two distinct classes of Batrachians and Reptiles,' and he is as little able to point out a character dividing the air-breathing from the water-breathing *Hæmatocrya*, the Reptiles from the Fishes. The following is the classification proposed:—

A. Subclass Reptilia.

Order 1. *Batrachia*.

Fam.: Anoura, Urodela.

Order 2. *Chelonia*.

Fam.: Terrestria, Paludinos, Fluvialia, Marina.

Order 3. *Ophidia*.

Fam.: Crotalidæ, Colubridæ, Hydrophidæ.

Order 4. *Lacertilia*.

Fam.: Chameleontidæ, Geckotidæ, Iguanidæ, Varanidæ, Teidæ, Lacertidæ, Chalcidæ, Scincidæ.

Order 5. *Crocodylia*.

Fam.: Procelia, Opisthocælia, Amphicælia.

Order 6. *Dinosauria*.

Fam.: Herbivora, Carnivora.

Order 7. *Thecodontia*.

Order 8. *Pterosauria*.

Order 9. *Anomodontia*.

Fam.: Diconodontia, Cryptodontia, Cycodontia.

Order 10. *Sauropterygia*.

Fam.: Plesiosauria, Simosauria.

Order 11. *Ichthyopterygia*.

Order 12. *Labyrinthodontia*.

Order 13. *Ganocephala*.

B. Subclass Pisces.

Order 14. *Plagiostomi*.

Fam.: Hypodontidæ, Cestraciontidæ, Notidanidæ, Spinacidæ, Scyllidæ.

HÆMODORACEÆ

Nictitantes, Lamnidæ, Alopecidæ, Scymniidæ, Squatinæ, Zyganidæ, Pristidæ, Rhinobatidæ, Torpedinidæ, Rairidæ, Trygonidæ, Myliobatidæ, Cephalopteridæ.

Order 15. *Holocephali*.

Fam.: Chimæroidæ, Edaphodontidæ.

Order 16. *Protopteri*.

Fam.: Sirenoidei.

Order 17. *Placoganoidei*.

Order 18. *Ganoidei*.

Fam.: Salamandroidei, Pycnodontidæ, Lepidoidei, Sturionidæ, Acanthodei, Dipteridæ, Cephalospidæ.

Order 19. *Lophobranchii*.

Fam.: Hippocampidæ, Syngnathidæ.

Order 20. *Plectognathi*.

Fam.: Balistinæ, Ostraciones, Gymnodontes.

Order 21. *Acanthopteri*.

Fam.: Percidæ, Sclerogenidæ, Scianidæ, Labyrinthobranchii, Mugilidæ, Notacanthidæ, Scomberidæ, Squamipennes, Tænioidei, Thentidæ, Fistularidæ, Gobiidæ, Blenniidæ, Lophiidæ.

Order 22. *Anacanthini*.

Fam.: (Apodes) Ophidiidæ, (Thoracici) Gadidæ, Pleuronectidæ.

Order 23. *Pharyngognathi*.

Fam.: (Malacopterygii) Scomberosidæ, (Acanthopterygii) Chroniidæ, Cyclabridæ, Ctenolabridæ.

Order 24. *Malacopteri*.

Fam.: (Apodes) Symbranchidæ, Murænidæ, Gymnotidæ, (Abdominales) Heteropygii, Clupeidæ, Salmonidæ, Scopelidæ, Characini, Galaxidæ, Esocidæ, Mormyridæ, Cyprinodontidæ, Cyprinidæ, Siluridæ.

Order 25. *Dermopteri*.

Fam.: Amphioxidæ.

Order 26. *Cyclostomi*.

Fam.: Myxinidæ, Petromyzontidæ.

Hæmatology (Gr. *αἷμα*, and *λόγος*). The doctrine of the blood.

Hæmatosine (Gr. *αἷμα*). The red colouring matter of the blood.

Hæmatoryline. The colouring principle of the wood of the *Hæmatosylon campechianum* or logwood.

Hæmatosylon (Gr. *αἷμα*, and *ξύλον*, wood). The Logwood-tree, *H. campechianum*, is one of the most useful and important of dye woods. It forms a tree of about forty feet high, the smaller branches covered with white bark and often spiny, the leaves pinnate with few small leaflets, and the flowers yellow in axillary racemes. It belongs to a peculiar group of Leguminous plants called *Cæsalpinieæ*, and is a native of the bay of Campeachy in Yucatan. The wood is of a deep dull brownish red, and is imported in logs of about three feet long.

Hæmaturia (Gr. *αἷμα*, and *οὐρον*, urine). A discharge of bloody urine.

Hæmodoraceæ (Hæmodorum, one of the genera). A natural order of Endogens of the Narcissal alliance, principally inhabiting New

Holland. They differ from *Amaryllidaceæ* in their flowers and equitant leaves; from *Iridaceæ* in their stamens, and in their anthers bursting inwards. They are curious, but not useful or beautiful plants; except in the case of *Anigoxanthus*, a genus containing some striking herbaceous species.

Hæmoptysis (Gr. *αἷμα*, blood, and *πύσις*, I spit). The coughing up of blood, sometimes produced by fullness of the blood-vessels of the lungs, or by the rupture of blood-vessels as a consequence of ulceration. It is distinguished from blood coming from the stomach by its usual florid colour: the latter is generally blackened by the acid, and often mixed with the contents of the stomach. The age at which this disease commonly shows itself is from fifteen to five-and-twenty, and it is sometimes brought on by violent exercise or a fit of coughing. It is not very uncommon as a symptom of suppression of some natural evacuation; and when unattended by symptoms of consumption and constitutional cough, and occurring in persons otherwise strong and healthy, it is often not dangerous. Bleeding, aperients, acids, diaphoretics, nauseants, and occasionally the exhibition of small doses of sugar of lead and of styptic astringents, are the remedies usually resorted to.

Hæmorrhage (Gr. *αἱμορροία*, from *αἷμα*, and *ρῆσις*, I break). A bleeding or flow of blood. This may arise from two causes: either a full state of the vessels, or *plethora*, when it has been called *active hæmorrhage*; or from a debilitated state of the vessels, or of the system generally, when it is called *passive hæmorrhage*. When hæmorrhage occurs from either of these causes, it usually requires methods of treatment adapted to the particular case. Where hæmorrhage is the consequence of wounds, the bleeding vessels must be secured by ligature; or where this cannot be done, styptics are applied.

Hæmorrhoids (Gr. *αἱμορροΐδες*, from *αἷμα*, and *ῥέω*, I flow). Tumours of the veins of the rectum, constituting the disease commonly called *piles*.

Heresiarch or **Heresiarch** (Gr. *αἱρεσιάρχης*). In Ecclesiastical History, the founder of an heretical sect. [HERESY.]

Hæretico Comburendo (Lat.). The title given to the writ which ordered the execution, by burning, of persons delivered over by the spiritual to the secular court for heresy.

Hagfish. A vernacular name for a species of cyclostomous fish, called *Myxine glutinosa*, and *Gastrobranchus cæcus*, by ichthyologists.

Hagiographa (Gr.). The Holy Scriptures. The term is also applied to histories or legends respecting the lives and actions of the saints.

Haidingerite. A double sulphide of antimony and iron, named after Haidinger.

Hail (Ger. *hagel*). Hail occurs chiefly in spring and summer, not unfrequently accompanied with thunder. It is formed of rain congealed by cold in the upper regions of the atmosphere. On an attentive examination of their

interior structure, hailstones are usually found to contain an opaque nucleus of a spongy or porous texture, resembling hardened snow, surrounded by a layer of ice of greater or less transparency. Sometimes several transparent layers are distinguishable, and sometimes the layers are alternately transparent and opaque. Hailstones have also been observed having a radiating structure. Their form varies greatly; in general it is roundish, but sometimes pyramidal, angular, or even thin and flat, with irregular surfaces. The usual size of hailstones is about an eighth to a quarter of an inch in diameter; but they are frequently of much greater magnitude, and instances are on record in which the dimensions would appear incredible, if they were not attested by observers of known character. Halley relates that on April 9, 1697, there fell in Flintshire hailstones which weighed 5 ounces. On May 4, 1697, Robert Taylor, in Hertfordshire, observed hailstones which measured 14 inches in circumference; that is, about 4 inches in diameter. Parent, on May 16, 1703, found them at Illiers as large as his fist. On July 11, 1763, at Toul, some were collected by Montignot measuring 3 inches in diameter. Volta affirms that on the night of August 19, 1787, in a hailstorm which ravaged the city of Como and its environs, some of the stones were found to weigh 9 ounces. In the terrible hailstorm which traversed the whole of France and the Netherlands on July 13, 1788, M. Tessier relates that hailstones were picked up which weighed 8 ounces. And Dr. Nogerath informs us that on May 7, 1822, hailstones fell at Bonn, weighing from 12 to 13 ounces. From such accounts we may form some idea of the destruction occasioned by a severe hailstorm in a cultivated country.

Of the different circumstances accompanying a fall of hail, the following are the most remarkable: Hail usually precedes storms of rain, sometimes accompanies them; but never, or very rarely, follows them, especially if the rain is of any duration. The time of its continuance is always very short, generally only a few minutes, and very seldom so long as a quarter of an hour. The quantity of ice which falls from the clouds in so short a time is prodigious, the ground being sometimes covered with it to the depth of several inches. The clouds from which hail is precipitated appear to be of very considerable extent and depth, as they produce a great obscurity. It has been remarked that they have a peculiar grey or reddish colour, and that their lower surfaces present enormous protuberances, while their edges exhibit deep and numerous indentations. Hail is always accompanied with electric phenomena.

Various hypotheses have been proposed to explain the physical cause of hail, and the phenomena by which it is accompanied; but notwithstanding all that has been written on the subject, the theory of hail is still involved in great obscurity.

Hair (Ger. *haar*). The characteristic co-

HAIR

vering of the Mammiferous class of animals. It consists of slender more or less elongated horny filaments, secreted by a matrix, consisting of a conical gland or bulb, and a capsule, which is situated in the mesh-work of the corium or true skin. The hairs pass out through canals in the corium, which are lined by a thin layer of cuticle adherent to the base of the hair: the straightness or curl of the hair depends on the form of the canal through which it passes. Spines, bristles, fur, and wool are all modifications of hair, having the same chemical composition, mode of formation, and general structure.

In the spines of the porcupine the bulb secretes a fluted pith, and the capsule invests it with a horny sheath, the transparency of which allows the ridges of the central part to be seen. In the spines of the hedgehog, the spine-like whiskers of the walrus, and the bristles of the hog, the twofold structure of the hair is very conspicuous; but in the finer kind of hair, as of the human head and beard, the central pith can only be demonstrated in fine transverse sections viewed with a microscope. Some kinds of hair, as of the human head, and that of the mane and tail of the horse, are perennial, and grow continuously by a persistent activity of the formative capsule and pulp; other kinds, as the ordinary hair of the horse, cow, and deer, are annual, and the coat is shed at particular seasons. In the deer the horns are shed contemporaneously with the deciduous hair.

Many quadrupeds, especially those of cold climates, have two kinds of hair: a long and coarse kind, forming their visible external covering; and a shorter, finer, and more abundant kind, which lies close to the skin, and is called *fur*. It is one of the processes in the arts to remove the coarse hair, and leave the fur attached to the dried skin, as in the preparation of seal-skin, &c. The peculiar characteristic of wool, and that on which its valuable qualities chiefly depend, is the serrated character of its surface, arising from its structure, which consists of a series or succession of inverted cones, the base of each being directed from the root of the woolly fibre, and receiving the apex of the succeeding cone. It results from this structure that the pressure to which the workman subjects the wool in moving it backwards and forwards, brings the fibres together and multiplies their points of contact. The agitation gives to each hair a progressive motion towards the root, and the serrations of one hair fix themselves on those of another hair which happens to have its root turned in the opposite direction, and the mass at length assumes that compact form which is termed *felted* wool. The microscope has likewise demonstrated various other remarkable modifications in the form of the hair in different quadrupeds. In the mole, for instance, each hair is alternately constricted and expanded from its root to its apex, whereby it readily assumes any position, and lies flat and

HAIRS

moving forwards. The organisation of the hair is such as to allow of its undergoing certain changes when once formed, according to the state of health and general condition of the rest of the frame. Some of the lower animals, as the Alpine hare, are subject to periodical change of colour of their fur, by which it is made to harmonise with the prevailing hue of the ground which they habitually traverse.

The chemical properties of hair were first pointed out by Mr. Hatchett, in his paper in the *Phil. Trans.* for 1800. It chiefly consists of an indurated albumen, and when boiled with water it yields a portion of gelatine. Soft flexible hair, which easily loses its curl, is that which is most gelatinous. Vauquelin discovered two kinds of oil in hair: the one colourless, and in all hair; the other coloured, and imparting the peculiar tint to hair. Black hair also contains iron and sulphur.

Hair, Colour of.—The prevalent popular belief that the hair of persons under strong emotions of grief or terror undergoes a change of colour, does not appear to rest on any sure foundation. Haller, in his *Elementa Physiologiae*, refers to eight authorities for examples of such changes, admitting that under the influence of impaired health such a change may take place slowly. The case of Marie Antoinette comes under the condition admitted by Haller. Had it been possible for mental emotion, whether of terror or of grief, to render hair suddenly grey, surely in the queen's case the change should have been witnessed at an earlier period than that of the arrest of the royal family in their attempt to leave France. No authentically recorded instance of such change has been ascertained to take place amongst men prematurely worn out in various climates, or amongst soldiers engaged in an active campaign amidst all the dangers and horrors of war. The *Transactions of the Royal Society*, extending over 200 years, do not contain an instance of such change in the colour of the hair; a circumstance opposed to the conclusion that it ever took place, for had it ever been undoubtedly witnessed, it is not likely it would have remained undescribed. (Dr. J. Davy, British Association, 1861.)

Hair Pencils. A term applied by artists to the small brushes used in painting, and often termed *camel's hair* pencils; they are composed of fine hairs, especially of the martin, badger, minerer, polecat, &c., and are mounted, when small, in quills; but when larger, in tinned iron tubes.

Hair Salt. Efflorescent sulphate of magnesia.

Hair Trigger. [TRIGGER.]

Hair's Breadth. The forty-eighth part of an inch is sometimes so called.

Hairs. In Botany, minute transparent filiform processes, composed of cellular tissue more or less elongated and arranged in a single row.

HAIRBELL

protectors of the surface in which they grow. Many sorts are distinguished, the principal of which are the secreting or glandular hairs, which are composed of cellulose that are visibly distended either at the apex or base into receptacles of fluid; and the lymphatic, which consist of tissue tapering gradually from the base to the apex.

Hairbell. The *Campanula rotundifolia*, a wild flower common in chalky pastures and wastes. The name is sometimes written Harebell. It is the Blue-bell of Scotland.

Halberd or Halbert (Mr. Wedgwood connects this word with the Swiss halm, *a handle*, and Ger. barte, *a broad axe*). An offensive weapon, consisting of a long pole or shaft, with a steel head somewhat in the form of an axe, with a spike or hook at the back. It was much used in the English army in the sixteenth century, and gave its name to troops called *halberdiers*, to whom was confided the defence of the colours, with otherspecial duties. It is now rarely to be met with except in some boroughs in Scotland, where it is used by the civic officers who attend the magistrates on public occasions.

Halcyon. [ALCEDO.]

Halcyon Days. A name given by the ancients to the seven days that precede and follow the winter solstice, from the circumstance of the halcyon or alcedo selecting that period for incubation. While this process was going on, the weather was generally remarkable for its calmness; and hence the expression has passed into a proverb, signifying *days of peace and tranquillity*.

Halcyonidae (Gr. *ἀλκυών*, *a kingfisher*). The family of Pisirostral birds, having the kingfisher as the type.

Half-moon. In Fortification. [DEMLUNE; RAVELIN.]

Half-pay. In the Army, is granted as a remuneration for past military services, either to an officer who retires altogether from active duty after twenty-five years' service, or to one who is compelled by some exceptional causes, as ill-health, reduction of his regiment, &c., to quit active service for a time. In the latter case the receipt of half-pay involves an obligation to return to duty when called upon, unless physically disqualified. The rates of half-pay are somewhat in excess of half the rates of full pay. The laws concerning half-pay, its liabilities and its rights, are extremely complicated, and will be found at length in the War Office Regulations.

In the Royal Navy, half-pay has more the nature of a retaining fee. Active employment is exceptional (during peace) in the higher ranks, and in the lower ranks it is frequently not to be had. When this is the case, the officer is placed on half-pay, often for years together. When an officer is too old for service he *retires* on half-pay, generally obtaining a step of honorary promotion.

The charge in 1865 is:—

For Army half-pay . . .	£342,486
For Navy half-pay . . .	698,195
Total	£1,040,681

HALO

Halitidae (Gr. *ἅλς*, *the sea*, and *ὄψ*, *the ear*). A family of Gasteropodous Mollusca, having as its type the genus *Halotis*, or the

Halispungia (Gr. *ἅλς*, *the sea*, and *σπόγγος*, *a sponge*). The generic type of a group of sponges distinguished by the presence of *silicious* spicules.

Halitherium (Gr. *ἅλς*, *sea*, and *θηρίον*, *beast*). A genus of *Sirenia*, allied to the Manatee; its teeth were erroneously referred by Cuvier to the genus *Hippopotamus*. It is found in the Miocene deposits.

Halitus (Lat. *vapour*). In Physiology, this term is applied to the vapour which rises from newly-drawn blood, and which has a peculiar odour.

Hall. [COLLEGE.]

Hallelujah (Heb. *praise ye the Lord*). A well-known doxology, derived from the Old Testament. It was used, among the early Christians, at Easter, and during the interval thence to Whitsuntide.

Halliards, Hauliards, or Halyards. Ropes by which signals are hoisted.

Halite. The subsulphate of alumina found at Halle.

Hallowmas. The time from November 1 to February 2, or Candlemas, was so called. [ALL-HALLOWES.]

Halloylite. A mineral named after M. d'Halloyl. It is a hydrated silicate of alumina.

Halo (Lat. *halos*, Gr. *ἅλως*). In Meteorology, a luminous circle or ring, usually coloured, surrounding the sun or moon under certain conditions of the atmosphere. Of such rings there are two kinds, each apparently depending on essentially different physical causes. The first are of small dimensions, their diameters being between 5° and 12°; generally three or more concentric rings appear together, differently coloured, and presenting appearances similar to the optical phenomena of the rings of thin plates. These are usually called *corona*; and they appear either when a small quantity of aqueous vapour is diffused through the atmosphere, or when light fleecy clouds pass over the sun or moon. The second kind consists usually of a single luminous ring, but of much larger dimensions, the diameter being about 45°. It is to appearances of this second kind that the term *halo* is usually appropriated.

The apparent diameters of halos of the second kind have frequently been measured, and are always found to subtend at the eye of the observer an angle of between 44° and 46°. The lunar halo is simply a white luminous circle, without colour, excepting a pale red, which sometimes fringes the interior edge of the circle. But the colours of the halos about the sun, though not so bright as those of the rainbow, are marked with sufficient distinctness. The red occupies the interior part of the luminous circle; the indigo and violet the outer part, shading away by insensible degrees till they are blended with the general colour of the sky. In some circumstances a second halo is observed concen-

tric with the former, but of much larger extent, its apparent diameter being about 90° . The colours of this secondary halo are faint and pale, and its luminousness much inferior to that of the inner halo. The halos are very frequently attended by a horizontal white circle, with brighter spots, or *parhelia*, near their intersections with the circle, and with portions of inverted arches of various curvatures. [PARHELIA.]

Various causes have been assigned for the origin of halos; but the most probable is that of Mariotte, who supposes the phenomenon to arise from the refraction of light in passing through small transparent and prismatic crystals of ice floating in the higher regions of the atmosphere.

Water assumes, in congealing, a great variety of crystalline forms, among which are most frequently found crystals whose faces are inclined to each other in an angle of 60° ; thus forming prisms of ice of which the refracting angle is 60° . These prisms are turned in all possible directions, and consequently the sun's rays fall on their faces at all different inclinations. But in certain positions of the prism with respect to the incident light, the rays which traverse it suffer a minimum deviation; this happens when the refracted ray makes an isosceles triangle with the two sides of the prism. The path of the ray in the interior of the crystal in this case makes an angle of 60° with the face of the crystal, or an angle of 30° with the perpendicular to that face. This last angle is the angle of refraction; and it is known by experiment that in the case of ice, the angle of refraction being 30° , the angle of incidence is 41° ; hence the ray falls on the crystal at an angle of $90^\circ - 41^\circ = 49^\circ$; consequently the deviation of the ray from its original direction is $60^\circ - 49^\circ = 11^\circ$. On escaping from the crystal, the ray suffers a second flexure of the same amount; and the total deviation from its first direction is now $2 \times 11^\circ = 22^\circ$, which is the semidiameter of the halo. It follows, therefore that the parallel

rays S A, S B, from the sun falling on such prisms, at A and B at angles of incidence equal to 41° , will be refracted into the directions A E and B E, which make angles A E S and B E S equal to 22° ; and an eye situated at the intersection E will see a luminous circle of which the apparent diameter, or angle A E B, is about 44° . With respect to the secondary or external halo, whose diameter is about 90° , it may be attributed, says Dr. Young (*Lectures*, vol. i. p. 348), either to two successive refractions through different prisms, or with greater probability, as Mr. Cavendish suggested, to the refraction of the rectangular terminations of the prisms.

This theory explains the order in which the colours are disposed. The ratio of the refraction of the violet ray being greater than that of the red ray, the former will suffer a greater deviation, and consequently the violet band of the halo will have a greater dia-

meter than the red. Supposing this theory to be correct, the condition necessary for the appearance of halos is the existence of particles of ice in the upper regions of the atmosphere. The appearance of a halo, therefore, furnishes information respecting the temperature of the air at great altitudes above the earth.

The parhelic, horizontal, and vertical circles which are white are due evidently to *reflection*. They are never observed unless a *cirrus* or *cirrostratus* cloud is between the spectator and the luminary which gives rise to them.

The formation of *coronæ*, or the small halos so frequently seen round the sun and moon in fine weather, is ascribed by Fraunhofer and Sir John Leslie, not to the refraction but to the diffraction of light in passing by the small watery globules suspended in the atmosphere. If a piece of tinfoil punctured with the point of a needle be held close to the eye, the sun will appear through it surrounded with a halo very near his disc, but spreading more in proportion as the hole is contracted. Supposing that an aqueous globule of equal dimensions would produce an equal diffraction, the magnitude of the globules might thus be inferred from the diameter of the halo. When the halo approaches nearest to the luminous body, the largest globules are floating, and therefore the atmosphere is surcharged with humidity; whence the justness of the remark that a dense halo close to the moon portends rain. For a full exposition of the theory of halos and other similar meteors, the reader is referred to a Memoir by Fraunhofer in Schumacher's *Astronomische Abhandlungen*, 3tes heft; or to the article 'Hof,' in Gehler's *Physicalisches Wörterbuch*. See also Newton's *Optics*; Smith's *Optics*; Pouillet, *Éléments de Physique*; *Cabinet Cyclopædia*, art. 'Optics'; *Encyclopædia Britannica*, art. 'Meteorology.'

Halogens (Gr. *ἅλς*, salt). Substances which by combination with metals produce saline compounds; such as chlorine, iodine, bromine, fluorine, which are simple halogens; and cyanogen, which is a compound halogen.

Haloragaceæ (Haloragis, one of the genera). An order of water plants belonging to the Myrtal alliance, of little use generally, though *Trapa natans* and other species furnish fruits with edible kernels, and are sometimes called *water-chestnuts*.

Haltica (Gr. *ἅλτικος*, good at leaping). A genus embracing numerous species of small and often minute Coleopterous insects, of the family *Galerucideæ*, and section *Tetramera*. These insects have the femoral joints of the hind legs thick and strong, and are consequently good leapers. The native species are smaller than the foreign ones, but are more noxious than might be expected from their diminutive size. The notorious turnip-fly, or rather turnip-flea (*Chrysomela nemorum* of Linnæus), is a species of the present genus.

Hamadryads (Gr. *ἡμαδρυάδες*). Nymphs supposed by the Greek and Roman poets to live and die with the trees to which they were attached.

HAMAMELIDACEÆ

Hamamelidaceæ (Hamamelis, one of the genera). A small order of epigynous Exogens, of the Umbellal alliance, consisting of small trees or shrubs found in various parts of the world, and allied on the one hand to *Bruniacea*, and on the other to *Cornaceæ*.

Hamites (Lat. hamus, a hook). A genus of extinct Cephalopoda, which inhabited chambered shells, losing their spiral form soon after their commencement and then continued for a considerable extent with a single bend upon themselves like a hook. The *Hamites* are found in the greensand formation in England.

Hamlet (dim. of A.-Sax. ham, home or house). A small village. In Law, a hamlet is a portion of a village or parish; according to Stow, the word meant originally the seat of a freeholder.

Hammer Beam. In Architecture, a horizontal piece of timber from, or near, that above the foot of a rafter, the object of which is to counteract the tendency of the rafter to an outward thrust. It is only used in Gothic roofs, and is of value as providing a counter-balance to the weight of the rafter.

Hammer of a Musket. That part of the lock which descends violently upon the percussion cap when the trigger is pulled.

Hammock (Span. hamaca). The sailor's bed. An oblong piece of hempen cloth; at each end are fastened several small lines, meeting in a grummet or iron ring; these form the *clews*. The whole, having a mattress and pillow, &c. placed in it, is hoisted up into its place by small ropes called *lanyards*, and suspended from hooks in the beams of the deck overhead, about nine feet asunder. The hammock is a very agreeable bed, especially in cold weather; but some little practice is needed at first to get in and out successfully. During the day the hammocks, lashed up tight with the mattresses and bedding rolled within, are stowed in the nettings along the upper edge of the bulwark.

In the language of some tribes in the West Indian islands, the word *hamac* denoted nets of cotton extended from two posts, and used as beds. From them the word was borrowed by the companions of Columbus, who transferred it to us through the Spanish word *hamaca*.

Hamster (a word of Ugrian origin). In Zoology, the *Mus Cricetus* of Linnæus, a rodent quadruped, somewhat larger than a rat, common in all the sandy regions that extend from the North of Germany to Siberia; extremely noxious from its fertility and great destruction of grain, but an object of interest on account of the economic instincts which conduce to its preservation and support. The hamster excavates a complicated burrow, consisting of different apartments for rearing the young, hibernating, and storing up winter food, often in enormous quantity. To effect this hoard, nature has provided the hamster with a means of transport in two large cheek-pouches, which, during its incursion among cultivated grounds, it crams full of grain, beans, or peas, and empties on its return to its hole

HANNO'S PERIPLUS

by pressing the two fore-paws against the cheeks. The hamster, however, is not wholly dependent upon its winter store for existence. During the inclement months, when the frost becomes severe, animation is in great measure suspended: respiration ceases, the animal heat falls, and a kind of vegetative life is maintained by a slow circulation of dark or venous blood through both sides of the heart. When the returning warmth of spring stimulates the organic machinery to its wonted activity, the awakened hamster finds in the nourishment which it has stored up the means of supplying the consequent waste, and of maintaining its vital energies. They are thus enabled to commence the business of procreation in April, and the female rears a litter of six or eight twice or thrice every year. In about three weeks the young are able to provide for themselves, and are driven from the holes of the parents. The hamster is the type of the genus *Cricetus* of Cuvier, characterised by the short tail and cheek-pouches. The teeth nearly resemble those of the rat.

Hamper Office. A common law office in the Court of Chancery, in which writs were anciently kept in small separate wicker baskets (hampers, *hanperia*), abolished by 5 & 6 Vict. c. 103, and duties transferred. Writs relating to the subject were deposited there; those concerning the crown in the Petty or Little Bag, whence another office of the same court is denominated.

Hand (a word common to all Teutonic dialects). A measure of four inches, by which the height of a horse is computed: also the parts of a horse—as *forehand*, for the head, neck, and fore quarters; and *hindhand*, which includes the rest. It also designates the hand of the rider; the *spur-hand* being the right hand, and the *bridle-hand* the left.

Hand Grenade. [GRENADE.]

Handloom. [WEAVING.]

Handspike. A stout ash pole, seven feet in length, used as a lever in the service of ordnance. It is round at the handle, and square towards the other end, the extremity of which is bevelled. When the handspike is used as a lever of the first kind, the bevelled side should be down; when used as a lever of the second kind, the bevelled side should be uppermost.

Handspike. A wooden lever employed on board a ship in working the windlass and capstan, one end being squared to fit the holes in the capstan head and in the barrel of the windlass.

Hank. In Spinning, the name given to two or more skeins of yarn, silk or cotton, when tied together. When single, they are called *skeins*.

Hanks. Rings of ash or iron, by which fore-and-aft sails are confined to the stays on which they are severally suspended and upon which stays the hanks slide while the sail is in process of being set or hauled down.

Hanno's Periplus. [PERIPLUS.]

HANSA

Hanse, or **Hanseatic League** (Ger. *hanse*, Gothic *hansa*, a *league*). In European History, a celebrated confederacy of cities on the coasts of the Baltic, and in the adjoining countries. The first league was formed in 1239, between Hamburg, Minden, and many other towns, to which Lübeck soon afterwards acceded: it was for the purpose of mutual defence against foreign potentates, especially the Danish king Waldemar, as well as the neighbouring nobles of Germany. The league rapidly spread, and comprehended, at one period, eighty-five cities, divided into four provinces. It had four chief foreign dépôts: at London, Bruges, Novgorod, and Bergen. In the fourteenth and fifteenth centuries the league became of high political importance, and made war and peace as an independent sovereign power, but it was never recognised by the German empire. Its decay was gradual, as the increased protection given to commerce by the princes of the several states in which these cities were situated rendered the alliance for mutual defence unnecessary.

Maquebut, Harquebus, Mackbut. [ARQUEBUSE.]

Harbour (Ger. *herberge*). A piece of navigable water communicating with the sea or with a navigable river, or lake, deep enough to receive large vessels, and protected from the effects of storms or heavy seas. Harbours must always be accompanied by a roadstead, in which vessels may await the high tides, if the harbour should be exposed to their action; and in all cases it is preferable that there should be an outer harbour, in which the ships frequenting the particular port should be able to bring up or to lose the way they retain from the open sea. Harbours are divided into harbours of refuge, tidal, and permanent harbours. In harbours of refuge all that is needed is to secure facility of entrance and safe berths for the vessels lying in them, together with great facilities for putting to sea; but as the vessels frequenting harbours of this class are usually destined for some other port, there will be no necessity for making enclosed docks where the ships might be free from the inconvenience of the tides. In tidal harbours such enclosed docks are wanted; for large vessels are rarely so built as to allow of their being beached, or unloaded upon the beach, when the ships are left by the tide. Permanent harbours may dispense with the works for the enclosure of the shipping; but they will be always unfit for the purpose of a commercial port, as ships unless always at the same level cannot be economically unloaded; in such seas as the Mediterranean, the Caspian, and the great lakes of America, this remark does not apply. Practically, permanent harbours are either military or civil. The first require large areas of water surface, where the ships may lie in ordinary, as at Plymouth, Portsmouth, Cherbourg, Brest, Toulon, &c.; the latter are usually smaller, and more compact, as Southampton, Falmouth, Liverpool, Glasgow, London, Havre, Bordeaux, &c.

HARELIP

Hard Bodies. In Natural Philosophy, bodies which resist pressure or percussion: in opposition to soft bodies, the parts of which readily yield to pressure, and do not recover themselves; and to elastic bodies, the parts of which also yield to pressure or impact, but presently recover themselves when the disturbing force ceases to act.

Hardness. In Mineralogy. Minerals may occasionally be distinguished and identified by their relative degrees of hardness; to specify which, various scales have been suggested, that of Mohs being perhaps the most simple. According to it the relative degrees of hardness are expressed in numbers, referring to the following standard substances, which are easily obtained in a state of purity, or crystallised; namely—

- | | |
|----------------|------------------------|
| 1. Talc. | 6. Adularia (Felspar). |
| 2. Rock-salt. | 7. Rock-crystal |
| 3. Calc-spar. | 8. Topaz. |
| 4. Fluor-spar. | 9. Corundum. |
| 5. Apatite. | 10. Diamond. |

Any mineral which neither scratches nor is scratched by any one of the above substances is said to possess the hardness expressed by the attached number. Thus if a mineral neither scratches nor is scratched by calcareous spar, its hardness is represented by 3; if it scratches felspar and not rock-crystal, its hardness is stated to be between 6 and 7.

Hardware. A generic term employed to signify such manufactures as are produced from the commoner or more useful metals; that is, iron and steel, brass and copper, zinc and tin, and occasionally certain commoner kinds of plated goods. The industry which is engaged in these products is seated chiefly in Warwickshire and certain parts of Yorkshire, and particularly in the towns of Birmingham, Wolverhampton, and Sheffield, though it is carried on also in many other localities.

According to the census of 1861, 117,418 persons were engaged in the manufacture of machines, 13,744 in that of arms, 316,572 in that of iron and steel, 45,677 in that of brass, 9,733 in that of copper, 760 in zinc. If we add to these the moiety of those engaged in tin and quicksilver manufactures, viz. 11,439, the aggregate of persons employed in the hardware industry is 516,243; and if we take the wages paid to such persons to average 16s. a week, and to represent the third in value of the commodities produced, the annual value of the hardware manufactured in England will amount to upwards of 60,000,000*l.* In all likelihood, however, this estimate is below the truth.

Hare. [LAGOMYS; LEPUS.]

Harebell. The *Hyacinthus non scriptus*, a wild flower common in woods and hedgerows, and sometimes called *Blue-bell*. [HAIRBELL.]

Harelip. A fissure or perpendicular division of the lip, so named from its supposed resemblance to the upper lip of a hare. Children are sometimes born with this malformation, and sometimes it is the consequence of accidents

HAREM

or wounds. It most usually affects the upper lip; and is not only a serious deformity, but may prevent the infant from sucking and cause impediment of speech. The cleft is sometimes double. This malformation admits of partial or entire relief by a surgical operation, which should generally not be performed upon very young infants, as there is a risk of causing convulsions.

Harem (Turk.). The name given to those apartments in the houses of the East which are appropriated exclusively to females. [SERAGLIO.]

Haricot (Fr.). The ripe seeds of various kinds of kidney bean, especially of *Phaseolus vulgaris*; used in cookery.

Harits. [CHARITES.]

Harlequin. In the Italian Comedy, the name given to the person who performs a part something similar to that of the clown or merry-andrew of the mountebank stages in our own country. Harlequin forms also one of the standing characters in the grotesque entertainments of the pantomime. The name is said to be derived from an Italian comedian who, from frequenting the house of M. de Harlay at Paris in the time of Henry VII., was called Harlequino or little Harlay. [PANTOMIME.]

Harmaline. A crystallisable alkaloid contained in the seeds of the *Peganum Harmala*.

Harmattan. The dry parching wind prevailing on the coast of Africa, between Cape Verd and Cape Lopez, in the months of December, January, and February.

Harmonia (Gr. *Ἀρμονία*). In Greek Mythology, according to some versions, a daughter of Ares and Aphroditè. She became the wife of Cadmus, the founder of Thebes, from whom she received the fatal necklace which brought about the deaths of Amphiaræos and Eriphylè. [EUROPA.]

Harmonic Axes. The harmonic axes of the r^{th} order, of any number n of rays of a plane pencil with respect to a fixed ray, are the r rays which pass through the harmonic centres, of the r^{th} order, of the n points in which the given rays cut any transversal; these centres being taken with respect to the point in which the same transversal is cut by the given fixed ray. [HARMONIC CENTRES.] The properties of such harmonic axes are correlative to those of harmonic centres.

Harmonic Centres. The harmonic centre of two points a_1, a_2 with respect to a pole o , in the same line with them, is, simply, the *harmonic conjugate* of o with respect to a_1 and a_2 . Calling it m , it is determined by the relation

$$oa_1 \quad oa_2$$

where each segment ma is to be understood as having a sign determined by the direction of the motion from m to a .

More generally m is said to be the harmonic centre, relative to o , of any number n of points a when

$$\sum \left(\frac{ma}{oa} \right) = 0,$$

HARMONIC MEAN

where the summation extends to the n fractions of which $\frac{am}{oa}$ is a type. Such a centre m was

formerly called by Poncelet the *centre of the harmonic mean* (Crelle's Journal, vol. iii.); further investigations, however, have led Jonquières and others to the consideration of harmonic centres of higher order; those of the r^{th} order being defined by the equation

$$\sum \left(\frac{ma}{oa} \right)^r = 0, \text{ where } \left(\frac{ma}{oa} \right)^r \text{ represents a pro-}$$

duct of r factors, of the type $\frac{ma}{oa}$ but formed

by taking for a , successively, any r of the given points, and the sign \sum extends to all the different products that can be so formed. An equivalent definition is given by the equation

$$\sum \left(\frac{1}{om} - \frac{1}{oa} \right)^r = 0,$$

whence it is manifest that there are always r harmonic centres of the r^{th} order. The harmonic centre of the first order is defined by the equation

$$\frac{n}{om} = \frac{1}{oa_1} + \frac{1}{oa_2} \quad \frac{1}{oa_n};$$

that is to say, om is the *harmonic mean* of the segments $oa_1, oa_2, \&c.$. .

Amongst the most important properties of harmonic centres are the following:—

1. If m be one of the harmonic centres, of the r^{th} order, of a given system of points with respect to a pole o , the latter is also a harmonic centre, of the $(n-r)^{\text{th}}$ order, of the same system with respect to the pole m .

2. The pole o being invariable, the harmonic centres of the r^{th} order of a given system of points coincide with the harmonic centres, of the same order, of the harmonic centres of any superior order.

3. If m_1, m_2, \dots, m_r be the harmonic centres, of the r^{th} order, of a given system of points, with respect to a pole o , and m'_1, m'_2, \dots, m'_r those of the r^{th} order of the same system of points with respect to another pole o' , then the harmonic centres of m_1, m_2, \dots, m_r of the $(r+r'-n)^{\text{th}}$ order, with respect to o' , will coincide with the harmonic centres of the order $(r+r'-n)$, of m'_1, m'_2, \dots, m'_r with respect to o .

4. The projections upon any other line of a number of points, of their harmonic centres of any order, and of the corresponding pole, retain all the properties of the original system.

The theory of harmonic centres plays an important part in modern geometry. Cotes, in his *Harmonia Mensurarum*, first showed that the locus of the harmonic centre, of the first order, with respect to a fixed pole o , of the intersections of a curve of the n^{th} order by a line which passes through that pole, is *always* a right line. It is now called the $(n-1)^{\text{th}}$ *polar* (or *polar line*) of o ; the r^{th} polar of o being the locus of harmonic centres of the $(n-r)^{\text{th}}$ order of the same intersection points.

Harmonic Mean. The second term of the harmonic progression whose first and third

HARMONIC PENCIL OF RAYS

terms are given quantities, is termed the *harmonic mean* of the latter. Hence, since the reciprocals of quantities in harmonic progression form an arithmetic series, the harmonic mean is the reciprocal of one half the sum of the reciprocals of the given quantities. Generalising this definition, the harmonic mean of any number of quantities is the reciprocal of the n^{th} part of the sum of their reciprocals.

Harmonic Pencil of Rays. A system of four lines through a point such that one of the three fundamental anharmonic ratios to which they give rise has the value -1 . [AN-HARMONIC RATIO.] Thus the pencil whose rays are OA, OB, OC, OD will be harmonic if

$$\sin(A B C D) = \frac{\sin A O C \sin A O D}{\sin C O B \sin D O B} = -1.$$

A harmonic pencil cuts every line in its plane harmonically, that is to say in a harmonic row of points, and all pencils are harmonic whose rays pass through four fixed harmonic points. Harmonic pencils and harmonic rows, therefore, have correlative properties. The term *harmonic conjugates* is applied, in the above case, to the two rays A and B, as well as to the two C and D. Three rays of a pencil being given, the harmonic conjugate of any one with respect to the two others is perfectly defined, and may easily be constructed by means of the properties of a complete quadrangle. [QUADRANGLE.] The bisectors of the angles made by two lines are harmonic conjugates with respect to these lines. They are obviously perpendicular to each other, and we may say conversely that when two conjugate rays of a harmonic pencil are at right angles to each other, they bisect the adjacent angles made by the other pair.

Similarly, a *harmonic pencil of planes* is a system of four planes passing through the same line such that, of the three fundamental anharmonic ratios to which they give rise, one has the value -1 . Any pencil of planes passing through the rays of a plane harmonic pencil, or through four harmonic points, will be itself harmonic. [ANHARMONIC RATIO.]

Harmonic Progression or Series. A series of numbers such that any three consecutive terms are in harmonic proportion. The principal property of this progression is, that the reciprocals of the terms form an arithmetic progression; and, conversely, the reciprocals of an arithmetic, form a harmonic progression.

Harmonic Ratio. [ANHARMONIC RATIO.]

Harmonic Row of Points. Four points in a line are said to form a *harmonic row* when, of the three fundamental *anharmonic ratios* which they determine, one has the value -1 , the others having the values $\frac{1}{2}$ and 2 . [ANHARMONIC RATIO.] Thus a, b, c, d will form a harmonic row if

$$(a b c d) = \frac{a c}{c b} + \frac{a d}{d b} = -1,$$

and in this case c and d are said to be *harmonic conjugates* with respect to a and b . The latter

HARMONIUM

are of course also harmonic conjugates with respect to the former, since obviously

$$(c d a b) = -1.$$

Estimated numerically, it is evident that the segment ab is the harmonic mean of the segments ac and ad , and that dc is the harmonic mean of db and da . Further, any two harmonic conjugates divide the line joining the other two into segments, which have the same ratio, the absolute value of the latter being alone considered.

Of two harmonic conjugates with respect to a given pair of distinct points a and b , one is perfectly defined when the other is given; one is always within, and the other without the segment ab . When one bisects ab , the other is infinitely distant, and from these extreme positions both move simultaneously towards a (or b), with which they ultimately and simultaneously coincide. The harmonic division of a line occurs very frequently in the higher geometry; it is most conveniently effected, geometrically by means of the properties of the diagonals of a *complete quadrilateral* [QUADRILATERAL]; algebraically it can be shown that if x denote the distance of any point of a line from an assumed origin, in the same, the quartic equation

$$a_0 x^4 + 4a_1 x^3 + 6a_2 x^2 + 4a_3 x + a^4 = 0$$

will represent four harmonic points provided the cubinvariant

$$a_0 a_2 a_4 + 2a_1 a_2 a_3 - a_0 a_3^2 - a_1 a_2^2 - a_2^3$$

vanishes.

Harmonic Triad. In Music, the chord of a note consisting of a third and perfect fifth, or, in other words, the common chord.

Harmonics. In Music, the doctrine of the mathematical relations of musical sounds to each other. This doctrine was by the ancients divided into seven parts; viz. of sounds, of intervals, of system, of the genera, of the tones or modes, of mutation, and of melopœia.

Harmonica. [MUSICAL GLASSES.]

Harmonical Interval. In Music, any interval which has definite harmonic relations between the numbers of vibrations of its constituent notes.

Harmonical Proportion, called also **Musical Proportion.** Three numbers are said to be in harmonical proportion when the first is to the third as the difference of the first and second is to the difference of the second and third: thus, 2, 3, and 6 are in harmonical proportion, because $2 : 6 :: 1 : 3$.

Harmonium. In Music, a musical instrument, somewhat resembling a small organ, and played with a clavier in the same manner. Its tones are produced by reeds, somewhat similar to those in the reed pipes of an organ, but left free at one end, and hence called *free reeds*. These are caused to vibrate by wind from bellows worked by the feet. The harmonium takes the place of an organ in houses or schools and small churches, and has of late years come into very extensive use.

HARMONY

(Gr. *ἁρμονία*). In Music, an agreeable combination of sounds heard at the same instant. As a continued succession of single musical sounds produces melody, so does a combination of several together produce harmony.

Harmony, Pre-established. A hypothesis invented by Leibnitz, to explain the correspondence between the course of our sensations and the series of changes actually going on in the universe, of which, according to that philosopher and many others, we have no direct knowledge. [PREFACE.] This hypothesis is connected, in the Leibnitzian system, with the doctrine of monads—certain spiritual powers or substances, one of which constitutes the principle of vitality and consciousness in every living being. Each of these is, in its degree, a mirror, in which the changes going on in the universe are reflected with greater or less fidelity. But between simple substances, such as spirit and matter, soul and body, no real reciprocal action can take place. The Author of the universe has consequently so ordained that the series of changes going on in any particular conscious monad, corresponds precisely to those of the monads in contiguity to which it is placed. Hence arises our belief that mind is acted on by matter, and vice versa; a belief which leads to no practical errors in virtue solely of this pre-established harmony. The subject of Leibnitz' theory has recently undergone fresh discussion in Mr. J. S. Mill's work on the *Philosophy of Sir William Hamilton*.

Harmony of the Scriptures, Gospels, &c. The correspondence of the several writers of different parts of the Scriptures in their respective narratives, or statements of doctrine. The earliest Harmony of the Gospels was composed by Tatian, in the second century, with the title *Diatessaron*. Among other works of this kind may be mentioned Osiander, *Harm. Evangelica*; Cartwright, *Harm. Ev. Commentario illustrata*, 1647; Le Clerc, *Harmonie Ev.* Amst. fol. 1699; Macknight's *Harmony of the Four Gospels*, 1756; Greswell, *Harmony and Dissertation*, Oxford 1830.

Harmostes (Gr. *ἁρμοστής*, from *ἁρμόζω*, *I fit*). In Ancient History, a Spartan magistrate, called also sometimes *sophonistes* (*σοφονιστής*, *moderator*), who was appointed to superintend a conquered state. It is conjectured, from Thucyd. iv. 53, that the office was annual. Other Greek states which made conquests afterwards borrowed the name. Xenophon speaks of Theban *harmoste* in Achaia.

Harmotome (Gr. *ἁρμότης*, *a joint*, and *τέμνω*, *I divide*). A mineral chiefly from Andreasberg, in the Harz, the crystals of which often intersect each other, and are easily separable. It is also called Cross-stone or Stauroelite. [CROSS-STONE.]

Harp (Ger. *harfe*). A musical stringed instrument of great antiquity, in which the strings are stretched on a triangularly formed frame, and pinched, or rather pulled, by the fingers, to set them in vibration and produce the differ-

HARPOCRATES

ent sounds. The harp is represented on many Egyptian monuments; and though it is usually admitted to be of Eastern origin, it seems doubtful whether it was known to the Greeks and Romans in any shape analogous to its present form. Of late years this instrument has been much improved by pedals and other devices.

Harp shells. [HARPA.]

Harpa (Ger. *harfe*). A genus of Pectinibranchiate Molluscs dismembered from the Linnæan *Buccinum*, and remarkable for the elegance of form and beauty of the markings of the shell: this is traversed by longitudinal compressed sinuous parallel ribs, which may be compared to the strings of a harp.

Harpalus (Gr. *ἁρπαλῆς*, *grasping, greedy*). A genus of predaceous Coleopterans, and the type of a family (*Harpalidae*), which is one of the principal divisions of the Linnæan genus *Carabus*.

The *Harpalidae* are divided into three principal sections, characterised by modifications of the anterior tarsi of the male.

1. *Harpalina*, having the four anterior tarsi of the males dilated.
2. *Feronina*, having the two anterior tarsi dilated, and the joints heart-shaped.
3. *Patellimana*, having the two anterior tarsi of the males dilated; the joints being square or rounded.

Each of these sections contains numerous subgenera, of which *Harpalus proper* contains many British species. *Harpalus ruficornis* is perhaps the most common; it exceeds half an inch in length, with opaque black elytra and body, and red legs and antennæ.

Harpax. A genus of fossil shells, oblong and somewhat triangular, the hinge being formed by two projecting teeth. (Parkinson.)

Harpies (Gr. *ἁρπυιαι*, from *ἁρπάζω*, *I seize*). In Mythology, a name for the storm-winds. (Gladstone's *Homer and the Homeric Age*, vol. ii. p. 300.) In Hesiod, they are represented as the beautiful daughters of Thaumas and Electra; but in later mythology they assume the repulsive form under which Virgil has exhibited them. (*Æn.* iii. 211 &c.)

Harpings (a word akin to *warping*). In a ship, those planks or wales, forming her outer covering, which bend in towards the bow and are fastened in the stem. They are thicker than other parts of the wales, to encounter the great resistance offered by the water as the ship cuts through it.

Cat-harpings.—Minor ropes between the tops and mastheads, employed to draw the shrouds together and inwards towards the mast. They serve to tighten the shrouds, and to give freer play to the yards and sails when braced far on either tack.

Harpocrates. The Grecised name of the Egyptian god Har-pi-chruti, i.e. (according to Bunsen and Lepsius) Horus the child, represented generally as a naked boy, sitting on a lotus flower, with his finger in his mouth, to denote (not, as is commonly supposed, silence, but) the childish actions of infancy.

H

HARPSICHORD

Harpsichord. A keyed musical instrument strung with wires like a pianoforte, in which the sounds are produced by means of small vertical sticks, called *jacks*, upon which the keys act as levers. In the jacks are inserted short pieces of quill; these, upon passing the strings, set them in vibration. This instrument is now superseded by the pianoforte.

Harpyia (Gr. *ἁρπυία*, *Harpy*). This term has been applied both to a genus of Raptorial birds and to a genus of Lepidopterous insects.

Harrier. A small hound trained for hunting the hare, remarkable for the acuteness of its sense of smell.

Harringtonite. A mineral compound of silica, alumina, lime, soda, and water, from the North of Ireland.

Harrow (Dan. *haro*). In Agriculture, a rhomboidal frame with a number of spikes inserted in it on one side. This frame, when dragged over ploughed land, breaks the furrow slices into small pieces, for the purpose of preparing the land for seed in some cases, and for covering the seed in others. The spikes are inserted in it, at such distances that when the frame is drawn along in a straight line, the tines, as they are technically termed, pass through every part of the soil traversed by the frame. Finlayson's harrow is an implement of the so-called grubber class, in which the frame is carried on wheels, the teeth being pointed forward so as to take hold of the land. This implement, by means of a long lever, can be regulated to such a nicety as to stir the soil to the depth of only one or two inches, for the purpose of covering grass or clover seeds; or it can be pressed into it so far as to serve, in the case of stubble lands, instead of ploughing. Wilkie's harrow and Kirkwood's harrow can be used for similar purposes; and being on a smaller scale can be worked with fewer horses than Finlayson's, which commonly requires four or six.

Harrowing. The process of drawing a harrow over the soil for the purpose of reducing it to a level, of covering seed, or of turning up weeds in ploughed ground, or moss in grass lands. In agriculture the harrow is drawn by horses; and in market-gardening, where a light harrow is sometimes used, by men. In either case the more rapid the motion of the harrow, up to a certain point, the more efficient will be its operation. For meadow lands, the object of harrowing is to disperse the little heaps of earth raised during winter and early spring by moles and worms. For this purpose the harrows in some parts of the country are turned upside down; while in others, as in Middlesex, thorn branches are tucked into a frame resembling a harrow, and dragged over the surface for the purpose of effecting the same object. This is called a *bush harrow*. A chain harrow is also used for the same purpose.

Hart. [DEER.]

Hartshorn, Spirit of. An impure solution of carbonate of ammonia, obtained by the destructive distillation of hart's horn or any kind

HAT

of horn or bone. An impure solid carbonate of ammonia, called *salt of hartshorn*, is formed at the same time.

Haruspices. [ARUSPICES.]

Harvest Bug. [CIMEX.]

Harvesting. The operation of pulling, cutting, rooting up, or gathering field crops, and drying or otherwise preparing them for being stored for winter use. The first harvest which occurs in Britain and similar climates is that of the forage grasses, or other plants made into hay; the next is the harvest of cereal grasses, or of corn crops; and the third the potato harvest, or harvest of root crops, such as potatoes, carrots, turnips, mangold wurzel, &c. There is also the harvest of occasional crops; such as that of rape-seed, turnip-seed, dyer's wood, hemp, flax, and various other articles.

Haschisch or **Hasheesh.** The Arabic name for Indian hemp, used as a stimulant in Eastern countries. The Assassins were said to nerve themselves for their horrible work by the excitement which it produced; hence their name. [ASSASSINS.]

Hastati (Lat. from *hasta*, a spear). One of the three grand divisions of the Roman infantry, so called because they were armed with spears. It consisted of young men in the flower of life, who were always drawn up in the first line of battle. The other two divisions were called *Principes* and *Triarii*; to which was added another, called *Velites*, or *light troops*, first employed, according to Livy (xxvii. 4) at the siege of Capua, B. C. 211.

Hastings Sands. The lower member of the Wealden group of deposits, developed in the south-eastern counties of Kent and Sussex. The lower beds are the friable sands of which Hastings Cliff is formed, and these are based on beds of shelly limestone and grit, alternating with some clays. Harder beds yielding good building stone overlie these, and above them are the Tilgate beds of calcareous grit, extensively quarried in Tilgate Forest near Horsham. The rocks at Tunbridge Wells and other places are very picturesque portions of the Hastings sand. Beds of ironstone were formerly worked in this deposit.

Hat (Ger. *hut*). What is usually called a *beaver hat* is made of a variety of furs, chiefly those of the hare and rabbit, mingled with wool, and in the best hats a proportion of beaver's fur; but the latter is altogether omitted in common *stuff hats*. The furs are mixed; the long hair is picked out; and they are then placed on a hurdle, which is shaken and made to vibrate by being struck with a bow-string; in this way the dust is shaken out, and the fibres are to a certain extent interwoven. [FELT.] A quantity of this mass of fur sufficient for one hat is called a *bat* or *capade* (Ure's *Dictionary*, art. 'Hat-making'); it is pressed, kneaded, and at length moulded so as to form a kind of conical cap, the irregularities or small fibres of the different furs entangling with each other so as to keep the whole adherent. The cap is then dipped into warm water acidulated by sulphuric

HATCH

acid, and wrought for several hours by the hands, by which it is thickened or full'd; the knots are picked out of it, fresh felt here and there added, and the beaver ultimately applied; the hat is then shaped, waterproofed by a lac varnish, tied upon a block, dyed, stiffened by the application of a solution of glue, steamed, brushed, and ironed; the brim is then trimmed, and it is ready for lining and binding.

Silk hats have a foundation of woollen felt, upon which a silk plush is afterwards applied.

Hatch (connected by Mr. Wedgwood with Dutch *heck*, a *barrier of lath*, and Swed. *häck*, a *hedge*, which last would also seem to be another form of the same word). The covering of a hatchway. In very bad weather the hatches are battened down, to keep the water which comes in upon the decks from getting below.

Hatchettine. A fusible wax-like substance, found occasionally in nodules of ironstone, named after Mr. Hatchett. It is usually placed by mineralogists amongst bitumens.

Hatchment. In Heraldry. [ACHIEVEMENT.]

Hatchway. A large opening in a ship's deck for communicating with the decks below, the hold, &c.; there are the fore, main, and after hatchways.

Hattemists. An ecclesiastical sect in Holland, so called from Pontian von Hattem, a minister in Zealand: nearly allied to the Verschorists. They arose in the latter part of the seventeenth century. They appear to have denied the expiatory sacrifice of Christ. It is added, that they denied the corruption of human nature, and the difference between moral good and evil.

Hatti-scheriff. An edict signed by the hand of the Sultan is so named in Turkey.

Hauberk (Old Ger. *halsberge*, A.-Sax. *heals-borg*, from *heals*, *the neck*, and *beorgan*, *to cover*). A piece of armour, supposed to be of German origin, common in the chain mail, or rather ringed mail, of the twelfth century; being a jacket or tunic, with wide sleeves reaching a little below the elbow, the hood being of one piece with it. The hauberk of ringed mail ceased to be worn about the reign of Henry III., when the Oriental chain mail, properly so called, came into fashion for a short period.

In France only persons possessed of a certain estate, called *un fief de hauber*, were permitted to wear a hauberk, which was the armour of a knight; esquires wore only a simple coat of mail, without the hood and hose.

Haugh. A Scotch term, applied to lands which in England would be called *meadow* or *pasture*.

Haul. The Sea term for pulling upon a rope directly.—*To haul the wind*, to bring the ship to sail close by the wind after running in some other direction.

Haunches (Old High Ger. *hlancha*, Fr. *hanche*). In Architecture and Engineering, the word *haunches* is used to express the filling in of the masonry required to make up the horizontal line of the structure, between the

HAWSE

voussoirs of the arches and the line of the string, which is generally introduced over the whole series. The haunches are, in fact, the horizontal filling introduced to complete the structure; and the radiating joints in the haunches of the old Westminster Bridge have always been regarded as both a theoretical and practical defect in that building. The purpose of the haunches is to bring down the pressure of the roadway, or of the superstructure, upon the arches, and this is done in the most effectual manner by directing the line of thrust normally to the arch; in some of Smeaton's and of the early Roman bridges, however, the haunches of the great arches are often lightened by the introduction of a small circular arch, which is formed in the masonry of the upper structure. Examples of this method of lightening the haunches of mediæval arches are found in Wells and Salisbury Cathedrals.

Haurient. In Heraldry, a term applied to a fish placed in pale, and having its head in chief, as if rising to the surface for air.

Hausmannite. Native oxide of manganese; so called in honour of Prof. Hausmann.

Haustellata (Lat. *haurio*, *I draw forth*). A name of a grand section of insects, including all those which in the perfect state have the oral apparatus adapted for suction.

Hautbois. [OBOE.]

Häüyne. A blue mineral in small granular or spherical masses, generally found in basalt or lava. Named after Häuy, the celebrated French mineralogist.

Haven (Ger. *hafen*). [HARBOUR.]

Haversack (Fr. *havre-sac*). A strong coarse linen bag for carrying provisions on a march.

Hawk. [FALCO.]

Hawk-moth. [SPHINX.]

Hawkers, Pedlars, Petty Chapmen. In Law, persons travelling from town to town with goods and merchandise for the purpose of sale. They are required to take out licenses under 50 Geo. III. c. 41. Wholesale traders are exempt from the provisions of this Act, as are also licensed auctioneers going from town to town.

Hawking. [FALCONRY.]

Hawse (A.-Sax. *hals*, *the neck*). The portion of sea immediately in front of a ship's bows, and extending from an imaginary line rising from her anchors. The cables pass through the *hawse holes*, which are made in the timbers and in the *hawse piece* outside. When the ship has two anchors down, and the cables diverge from each other, the hawse is said to be *clear*; when crossed by the ship turning half round, there is a *cross* in the hawse. Another cross makes an *elbow*; then a *round turn*: in the last two cases the hawse is said to be *fool*. The process of disengaging the cables is called *clearing hawse*. The danger of a foul hawse is, that if it comes on to blow, the cables cannot be veered from their friction against each other.

Freshening hawse is veering out a little cable to expose a new surface to the friction in the hawse hole, or across the cutwater.

HAWTHORN

Athwart hawse implies across the bows of a vessel at anchor.

Hawthorn. One of the common names of *Crataegus Oxyacantha*, the Whitethorn, May, Maybush, Quick, and Quickest of the rustics. It is one of the most beautiful of our small trees, and also one of the most useful, being everywhere employed as a most efficient live fence. Many improved varieties are cultivated in our shrubberies and demesnes, as the Scarlet, the Double Scarlet, the Double White, &c. The Glastonbury Thorn, another variety, begins to blow very early, so that in mild seasons it is occasionally met with in blossom at Christmas. In reference to the name Hawthorn, i.e. the Thorn of haws, heys or hedges (A.-Sax. *hagathorn*, *hæthorn* or *hegethorn*), Dr. Prior remarks that it is interesting as affording testimony to the use of hedges and the appropriations of flats of land, from a very early period in the history of the Germanic races. The term *haw*, he continues, is incorrectly applied to the fruit of this tree in the expression *hips and haws*, the latter word denoting really the fence on which it grows. Many other species of *Crataegus* are cultivated for ornamental purposes, and to these the general name of Thorn is also applied.

Haymaking. The operation of cutting down, drying, and preparing grasses and other forage plants for being stacked for winter use. The plants are mown down at the time when they are supposed to contain a maximum of nutritious juices, viz. when they are in full flower. Dry weather, and if possible that in which sunshine prevails, is chosen for this operation; and the mown material is spread out and turned over two or three times in the course of the same day in which it is cut. In the evening it is put into small heaps. In the morning of the second day these heaps are spread out, and turned over two or three times; and in the evening they are formed into heaps somewhat larger than they were the day before. If the weather has been remarkably warm and dry, these heaps in the course of the third day are carted away and made into a stack; but if the weather has been indifferent, the process of opening out the heaps and exposing them to the sun is repeated on the third day, and stack-making is not commenced till the fourth. The grand object in making hay is to preserve the colour and natural juices of the herbage, which is best done by continually turning it so as never to expose the same surface for any length of time to the direct influence of the sun. In stacking the hay the object is to preserve this green colour, and at the same time induce a slight degree of fermentation, which has the effect of rendering the fibres of the plants composing the hay more tender, and changing a part of the parenchymous matter into sugar. This sweet taste renders the hay more palatable to horses. The best directions for haymaking will be found in Middleton's *Agricultural Survey of Middlesex*.

HEADACHE

Hayward (A.-Sax. *haga*, Fr. *haie*, *hedge*). An officer anciently appointed in the lord's court to take care of the cattle of a manor, and prevent them from injuring the hedges or fences.

Hazel (A.-Sax. *hæsl* or *hæsel*). The common name of the Nut (*Corylus*), a deciduous shrub or low tree, commonly found in hedgerows and as undergrowth in woods. The fruit is well known for its use at dessert; but it is not the wild form *C. Avellana* which is usually so employed, but improved varieties, to which the names of Filberts and Cobnuts are applied. Nuts if dried in the sun, and thus thoroughly harvested, may be kept for use, in closed vessels or small casks, till the following spring. The chief thing to be guarded against is mouldiness arising from moisture retained in the husks. Common nuts, as imported, without the husks are of course much less liable to this inconvenience.

Head. The fore extremity of a ship. It generally means the cutwater, which is adorned with a figure. *By the head*, implies that the ship's head is depressed in the water. *Head sails*, *head yards*, are the sails and yards in the fore part of the ship.

Head of Water. The height which a column of water is submitted to is called in Engineering *the head*; it is measured from the upper surface of the lower stream to the upper surface of the reservoir producing the pressure; the effective pressure will be that indicated by this height diminished by the friction that the column of water undergoes in the pipes, and through any change of direction that may take place in them.

Headache. This is a common symptom in various diseases: it frequently occurs both in full and in debilitated habits, and also in persons who are otherwise healthy. One form of headache consists in a degree of torpor and of confusion, with a dull pain over the whole head, dimness of sight, and inability to attend to anything requiring thought or fixed attention. Sometimes it is referable to disordered stomach or bowels, but it also comes on without any such assignable cause. These headaches are relieved by nervous stimulants, such especially as camphor, ether, and ammonia. A cup of strong coffee or of green tea often acts like a charm; and if the pain prevents rest, a small dose of opium is sometimes necessary, with perfect rest and quiet. Some very troublesome cases are relieved by cold applications to the temples and the head, others by snuff and nasal stimulants. There is a peculiar form of headache which consists of throbbing and pain of one particular part, or sometimes over one side of the head; it lasts an hour or two and then goes off, and returns again at stated intervals. This is called *hemisrania* (the *mi-graine* of French, and the *megrin* of old English writers), and is often of a distinctly intermittent character. For its permanent cure bark or sulphate of quinia are in use; blisters behind the ears are also of service. In bilious or sick headache, emetics and purges are required.

HEADBOROUGH

Obstinate headaches are not unfrequently got rid of by change of air, scene, and occupation; especially where they are the result of excessive intellectual application.

Headborough (Sax. *borg*, *pledge*). The chief of the ten *pledges* in frankpledge [FRANKPLEDGE]; also styled *borsholder*, *tything-man*, &c.

Headers. In Architecture, bricks, or stones, laid with their heads, or short faces, in front, and their long faces in the body of the work.

Heading Courses. In Architecture, the horizontal courses, which consist entirely of headers, in opposition to stretchers, or stretching courses. [BOND, ENGLISH.]

Headland. In Geography, a term nearly synonymous with CAPE, MULL, NESS, or PROMONTORY [which see].

Headland or Head Ridge. In Agriculture, a ridge or border, commonly ten or twelve feet broad, which is continued round a field in some cases, and which in others is only formed at the two opposite sides, for the purpose of affording space for the horses to turn on while ploughing.

Headline. In Printing, the top line of a page in which the running title and folio are given. The divisions and subdivisions of a work, when they are set in lines, and chapters, are also called *heads*.

Headpieces. In Printing, ornaments placed at the top of the first page and of the pages beginning with books, chapters, &c., and which are therefore called *headpages*. The headpieces of the old MSS. and some of the early printed books were beautifully illuminated; but in course of time wood engravings, cast metal ornaments, flowers, and brass rules were made available for working with the types. Headpieces have been revived of late years; they are mostly copied from old works, but engraved in a finer style.

Headstock. In Machinery, the framing used for supporting the gudgeons of a wheel.

Healds. The harness for guiding the warp threads in a loom.

Healfang or Halsfang (A.-Sax. *a catching of the neck*). The old English name for the punishment of the pillory. The word was also applied to the fine paid in order to commute this punishment.

Hearing Trumpet. An instrument for concentrating sound, and conveying it to the ear. It is generally a short bent tube, wide at the one end where the sound enters, and narrow at the other where the ear is applied. The principle on which it acts is the reflection of sound at an angle equal to that at which it strikes a smooth surface; and accordingly the form of the instrument ought to be so regulated that the whole of the vibrations shall be collected into a focus at the smaller end. But it is not necessary that the form which theory points out should be very accurately observed; the principal advantage is gained by confining the advancing sound by a continual reflection, and preventing it from spreading laterally and being dissipated.

HEART WHEEL

Heart (Ger. *herz*, a word running through many languages of the Aryan family). The human heart is a hollow muscular organ of a somewhat conical shape, the broad part of which is called its *base*, and the smaller end its *apex*. Its base is placed upon the right of the bodies of the vertebrae, and its apex obliquely to the sixth rib on the left. Internally it is divided into a *right* and *left ventricle*; the former anterior, and the latter almost posterior, in consequence of the oblique manner in which it is placed. Its inferior surface rests upon the diaphragm. Attached to the base of the heart are two *auricles*, so called from their resemblance to the ear of an animal: they are muscular sacs. In the right auricle are four apertures; two of the *venae cavæ*, one of the coronary vein, and one an opening into the right ventricle. In the left auricle there are five apertures; namely, one into the left ventricle, and those of the four pulmonary veins. Each ventricle has two orifices; one from the auricle by which the blood enters, and another into the artery by which it passes out. They are supplied with valves; those at the arterial openings being called, from their form, *semilunar valves*; those at the orifice of the right auricle *tricuspid*, and those at the orifice of the left auricle *mitral*. The valve at the termination of the *vena cava inferior*, just within the auricle, is called the *valve of Eustachius*. The cavities are lined with a strong smooth membrane. The *pulmonary artery* arises from the right ventricle, and conveys venous blood to the lungs, where having been changed into arterial blood by the action of the air, it returns by the *pulmonary veins*, which terminate in the left auricle; the *venae cavæ*, which bring back the mass of venous blood from all parts of the body, terminating in the right auricle. The circle, therefore, which the blood takes is this: It is returned from the various parts of the body by the *venae cavæ* into the right auricle, whence it is forced into the right ventricle, and then through the lungs; whence it returns into the left auricle, and from it into the left ventricle; and thence, by the aorta, through the general arterial circulation. The substance of the heart is supplied by nerves and vessels of its own, which are called *coronary vessels*; the coronary arteries branch off from the aorta, and the coronary veins return their blood into the right auricle. The nerves are branches of the eighth and great intercostal pairs.

Heart Wheel. The name given to a well-known mechanical contrivance for converting a circular motion into an alternating rectilinear one, which is generally adopted in the machinery of cotton mills. It consists of an ellipse turned either on an axle, or by means of a winch and handle in one of its foci, or its centre, on whose edge a movable point or circle presses; the latter receives an alternating motion from the circumference of the ellipse, which in its motion presses it to different distances from the centre of motion. The practical disad-

HEART WOOD.

antages of this contrivance are, the inequality of pressure and of moving force which will be required at different parts of the rotation of the ellipse, and the consequent wearing of some parts of it before the remainder.

Heart Wood. In Botany, the English term for *duramen*. It is the central part of the trunk of a tree hardened by the deposition in its tissue of various secretions, which clog up the passages, and forbid the passage of anything through them.

Hearth (A.-Sax. *heorth*, another form of *earth*). The part of a furnace where the metal accumulates, and where it is finally separated from the impurities that may be present in the ore; it is situated at the bottom of the furnace a little above the mouth and the tuyeres. The term is also applied to part of an open furnace, where the metal is exposed to the action of fire.

Heartsease. [*VIOLA*.]

Heat (Ger. *hitze*). This term has been applied both to the sensation experienced on touching a hot body, and to the cause of that sensation: in the latter sense it is synonymous with the term *caloric*. The escape of heat through space is called the *radiation* of heat, and its communication by contact *conduction*. The term *specific heat* is applied to the quantity of thermometric heat required to raise equal weights of different substances to the same temperature. Thus, experiments prove that the quantity of heat which will raise olive oil two degrees will only raise water one degree; hence a pound of water at 212° may be said to contain twice as much heat, or to have twice the capacity for heat that belongs to oil: or the specific heat of water being = 1, that of oil is 0·5. When heat changes the state or form of bodies a large quantity disappears, and remains in them so long as they retain one form. To heat in this state of combination, and inappreciable by the thermometer, the term *latent heat* or *caloric of fluidity* has been applied. [EVAPORATION; EXPANSION; LIGHT; RADIANT HEAT; THERMOMETER; THERMOTICS.]

Heat, Dynamical Theory of. Two theories have been propounded to account for the phenomena of heat: *the material theory*, and *the dynamical or mechanical theory*. The material theory supposes heat to be a kind of subtle and imponderable matter, capable of being combined with ponderable matter and again separated from the latter. The dynamical theory assumes heat to be, not a peculiar kind of matter, but a peculiar motion of the ultimate particles of matter. It is well known that, by the rapid blows of a sledge-hammer, a piece of iron may be rendered almost red hot. The material theory would here account for its development, by assuming that the compression of the iron by the blows of the sledge had squeezed out, as it were, a quantity of the heat which previously existed in the interatomic spaces of the metal. The dynamical theory, however, maintains that the mechanical motion of the hammer, which is stopped or destroyed when it falls upon the iron, is converted into a

HEAVEN

motion of the ultimate particles, both of the sledge and of the iron upon which it falls: in fact, the motion of the hammer as a mass is transferred to the individual atoms of the hammer and of the piece of iron, and this atomic or molecular motion thus acquired constitutes heat. The limits of this article will not admit of the introduction of the experiments and reasoning by which the dynamical theory of heat has gradually but completely driven its rival from the field. For a masterly exposition of this and the whole subject of heat, the reader is referred to Tyndall's *Heat considered as a Mode of Motion*.

Heat Rays. This term is usually applied to the red rays of the spectrum, and to other rays which fall outside the red end of the spectrum, and which are consequently invisible. The modern theories of heat and light will not, however, permit of the conception that there can exist any ray of light, which, when absorbed, will not raise the temperature of the surface absorbing it; and therefore the division of the rays of the spectrum into heat rays and light rays is no longer strictly philosophical. It is, however, certain that those rays which produce the greatest heating effect and but little luminous effect are concentrated about the least refrangible end of the spectrum, while the most luminous rays are more refrangible, and are consequently thrown nearer to the violet extremity of the spectrum.

Heath or Heather (A.-Sax. *hæth*, Ger. *heide*). In a general sense the term *heath* is applied to waste land in which the prevailing plants consist of one or more of the common species of heath, especially *Calluna vulgaris*, the *Erica vulgaris* of Linnaeus. This plant covers many hundreds of acres in the Highlands of Scotland, in Ireland, and in similar climates on the Continent. It attains, in many places, the height of three or four feet; and is used for thatching houses, making besoms, and for a variety of other purposes. The tender tops form a substitute for mattresses in Highland cottages; and they are also eaten green and in a dried state by horses, cattle, and sheep, in countries where the grasses and clovers do not begin to grow till late in the spring. Other common species are *Erica Tetralix* and *E. cinerea*.

Heave (A.-Sax. *hebban*, Ger. *heben*). In Nautical phrase, to employ force to move great weights by the lever, &c.; as *to heave up* the anchor by the capstan or windlass; *to heave down* the ship, or pull her over on one side to get at a leak; also *to heave taut* (tight), or turn the capstan till the rope or chain applied to it becomes tight.

Heaven (A.-Sax. *heofon*). The Celestial Sphere, or Firmament, or Sky, in Astronomy, denotes the spaces in which the celestial bodies are placed, or through which they apparently perform their diurnal revolutions. The term *heaven* was frequently used by the ancients to denote the orb or sphere in which a celestial body appears to move; and hence the ancient astronomers assumed the existence of as many

HEAVY SPAR

heavens as they observed different and apparently independent motions. They supposed the various heavens to be solid, because they could not otherwise sustain the bodies placed in them; and spherical, because perfect motion must be performed in a circle which is formed by the section of a sphere; and crystalline, because the different bodies are visible, though their orbs include one another. The first heaven was that of the Moon, the second of Venus, the third of Mercury, the fourth of the Sun, the fifth of Mars, the sixth of Jupiter, and the seventh of Saturn. The eighth, which is that of the fixed stars, was called particularly the *firmament*. Ptolemy added a ninth, which was the *Primum Mobile*. All these reveries have been exploded by the discovery of the true system of the universe, and the laws of the planetary motions.

Heavy Spar. Native sulphate of baryta. This is a common mineral in many mining districts. It occurs in several crystalline forms, of which the cleavage is a right rhomboidal prism; it also occurs fibrous, radiated, and stalactitic. Some beautiful specimens of the latter variety have been found in Derbyshire of a brown colour. The crystals are usually white, or nearly colourless. The specific gravity of sulphate of baryta is 4.1 to 4.6. It consists of 77 baryta, 40 sulphuric acid, its equivalent being 117. It enters into the composition of some kinds of pottery, but it is chiefly used in the adulteration of white lead. [BARIUM.]

Hebdomadal Council. [CONGREGATION; CONVOCATION, HOUSE OF.]

Hebe (Gr. Ἥβη). In Grecian Mythology, the goddess of youth, whose office it was to hand round the nectar at the banquets of the gods. She answers to the Latin goddess Juventas.

Hebrew Language. A dialect of the Semitic family of languages. The books of the Old Testament are preserved to us in this language, which was most closely allied with that of the Phœnicians, Canaanites, and Carthaginians.

Hecate (Gr. Ἑκάτη). In Mythology, a goddess, not mentioned in Homer, but by later writers spoken of as a daughter of Perses and Asteriâ. Her name is the feminine form of Hecatos (the Far-shooter), applied to Phœbus, Apollo, and Helios (the Sun). In the Homeric Hymn, she aids Demeter (Ceres) in her search for Persephonê (Proserpine); in other versions of the myth she remained with the latter in the nether world. Statues were set up to her in market-places, and especially at cross-roads.

Hecatomb (Gr. ἑκατόμβη). Properly, a sacrifice of a hundred oxen; but the word is often used to signify a large sacrifice of any kind of victims.

Hecates. [HECATE.]

Hackle. An instrument used in separating the fibres of flax and placing them in parallel tresses.

Hectic Fever (Gr. ἑκτικός, from ἔξις, habit). A constitutional fever, attended by debility, a small quick pulse, paleness, loss of appetite,

HEDGEHOG

excessive perspiration, and emaciation. It generally affects more or less of an intermittent character; but the exacerbations and remissions are irregular, and the sweating stage is not followed by that relief which it usually announces in other febrile attacks. It is often symptomatic of some particular disease, and requires to be treated accordingly. Where this is not the case, or where it seems merely an attendant on general debility, a course of sarsaparilla and a milk diet are often very beneficial; but where this remedy induces perspiration and nauseates, much management is required in carrying it on for a sufficient length of time to prove of service.

Hectogramme. A French measure of weight = 100 grammes, or 1,543.4 English grains.

Hectolitre. A French measure of volume = 100 litres, or 6,102.8 English cubic inches.

Hectomètre. A French measure of length = 100 mètres, or 3,937 English inches.

Hecuba. In Mythology. [PARIS.]

Hedenbergite. A silicate of lime and iron, first described and analysed by Hedenberg, in Sweden.

Hedera (Lat.). The genus of the Ivy, belonging to the order *Arabiaceæ*, and consisting of scandent evergreen shrubs, climbing by means of short sucker-like rootlets, which cling to any surface with which they come in contact. Ivy is thus enabled to mount to the tops of the highest buildings or of the tallest trees. The Common European Ivy, *H. Helix*, yields a large number of varieties. There are other species peculiar to Africa—*H. canariensis*, and to Asia—*H. colchica* or *Ragneriana*, both of them well known in gardens.

Hederic Acid. A crystallisable acid contained in the seeds of the common Ivy (*Hedera Helix*). An alkaloid (*Hederine*) has also been obtained from the same source.

Hedge (A.-Sax. hegge, Fr. haie). A living fence or wall formed of woody plants, sown or planted in a line, and cut or clipped in such a manner as to form a compact mass of any degree of width and height that may be required for the purpose of shelter, separation, or defence. The fences most generally used in agriculture are made of the white thorn (*Cratægus oxyacantha*, Linn.), because it has spiny branches, and forms a strong defence against cattle. Fences for the purposes of shelter and separation are chiefly used in gardening, and for the most part are formed of evergreen shrubs, such as the holly, yew, box, &c.; or sub-evergreens, as the privet; or of flowering shrubs, as the *Cydonia japonica*; or of deciduous shrubs or trees with persistent leaves, as the hornbeam and beech. In the management of hedges of every description an important point is to keep them thick, and impervious to wind or to animals near the ground; for which purpose the section of the hedge should be made broader at the base than at the top, in order that the exterior leaves in every part of the hedge may enjoy in an equal degree the influence of light, air, and perpendicular rains.

Hedgehog. [EAMNACEUS.]

HEDYPHAN

Hedypphan. An arsenio-phosphate of lead and lime from Sweden.

Hedysarum (Gr. ἡδύς, *sweet*, and ἄρωμα, *a spice*). A genus of herbaceous or dwarf shrubby leguminosæ, several of which are familiar in gardens. To this genus belong the Camel's Thorn, *H. Alhagi*, which produces a manna-like substance; and also the Moving or Windmill plant, *H. gyrans*, whose leaves possess the curious property of moving their leaflets spontaneously in different and opposite directions, under the influence of light and warmth.

Heel. The after extremity of the ship's keel: also the foot of a mast.—*To heel over*, is to incline to one side.

Hegel, Philosophy of. [SCHELLING, PHILOSOPHY OF.]

Hegira. In Chronology, the era used by the Mohammedans in the computation of time. The epoch or first day of this celebrated era, so extensively employed in the East, corresponds to Friday, July 16, in the year 622 of the Christian era. It is a problem of some importance to convert dates expressed by the Mohammedan computation into the corresponding dates of our calendar; for effecting this it is necessary to be acquainted with the form of the Mohammedan year.

This year is strictly lunar; and the civil months are adjusted to the lunar months by means of a cycle of 30 years, containing 19 common years of 354 days, and eleven intercalary years of 355 days; the cycle thus containing 10,631 days, or 29 Julian years and 39 days. Each year is divided into 12 months, containing alternately 30 and 29 days, excepting that the last month of the intercalary year contains also 30 days. The intercalary years are the 2nd, 5th, 7th, 10th, 13th, 16th, 18th, 21st, 24th, 26th, and 29th of the cycle. The names of the Mohammedan months, with the number of days in each, are as follow:—

Days		Days	
Mohareem . . .	30	Shaban . . .	29
Saphar . . .	29	Ramadan . . .	30
Rabi' I. . .	30	Shawwal . . .	29
Rabi' II. . .	29	Dhu'l Kadah . . .	30
Jomadh I. . .	30	Dhu'l Hajah . . .	29
Jomadh II. . .	29	In inter-	
Regeb . . .	30	calary years . . .	
			30

Such are the chronological elements by means of which Mohammedan dates are reduced to the Christian era. The rule by which the reduction may be accomplished is as follows:—

1. Divide the number of years (of the Hegira) elapsed by 30; the quotient will be the number of cycles, and the remainder the number of years elapsed since the beginning of the current cycle. Call the quotient A, and the remainder B, and let x be the number of intercalary years in B; then the number of days that have elapsed from the commencement of the Hegira to the beginning of the year in which the date occurs is given by this formula:

$$10,631 A + 354 B + x;$$

for 10,631 is the number of days in the cycle, and 354 the number of days in the common lunar year. To the sum obtained by this for-

HEIGHTS

mula add the days since the beginning of the current year, and the result is the number of days from the commencement of the Hegira to the given date.

2. To the number of days from the commencement of the Hegira to the given date add the number of days between the commencement of our era and the Hegira, and the sum is the number of days from the first of our era to the given date. The number of days from the beginning of our era to the Hegira, or to July 16, 622, is 227,016.

3. Having now found the number of days from the Incarnation to the given date, it only remains to convert the sum into Julian years. For this purpose divide by 1,461 (the number of days in the Julian intercalary period), and call the quotient C. Divide the remainder by 365, and call the quotient D, and the remainder of this last division y . Then $4C + D$ is the number of Julian years elapsed since the beginning of the Christian era, and y is the number of days that have elapsed of the current year. This gives the date in Old Style. To reduce it to the Gregorian Style, it is only necessary (during the present century) to add twelve days. [CALENDAR.]

Height (Ger. *hohheit*). In Geometry, the same as ALTITUDE [which see].

Heighten (from *height*). In Painting, a verb signifying to make prominent by means of touches of light or brilliant colours, as contrasted with the shadows; the effect is also heightened by deepening the shadows.

Heights, Measurement of. The determination of the relative altitudes of points on the earth's surface is of equal importance in physical geography with the determination of their latitudes and longitudes. There are three different methods by which the operation is usually effected. When it is required to determine not only the height of one point or station relatively to another, but the relative heights of a number of points above a common horizontal plane (as for tracing the line of a canal), recourse is had to the operation of levelling. The second method is to observe the angle of elevation or depression of one station as seen from another, and to compute, from the observation and from the distance of the two stations, the difference of altitude by the rules of trigonometry. The third method, and the most important, as being, generally speaking, the most applicable, is to deduce, by means of the known physical properties of the atmosphere, the differences of vertical height from the observed differences of atmospheric pressure as indicated by the barometer.

The following approximate formula for calculating the difference of altitude z , in feet, between two stations at which h and h' are the heights, in inches, of the mercurial column, is frequently used:

$$z = k (\log h - \log h').$$

In this formula common logarithms are to be employed, and k and c are to be previously determined by the following formulæ, in which

HEIMIA

τ and τ' denote the temperatures, centigrade, of the mercury at the two stations, t and t' the temperatures of the air, and l the latitude:

$$k = \frac{60345}{1 - 0.0257 \cos 2l} \left(1 + \frac{t + t'}{500} \right),$$

$$c = 1 + \frac{\tau - \tau'}{5550}.$$

The method of obtaining these formulæ is given by Poisson in his *Mécanique*, t. 2. In Biot's *Astronomie Physique*, and Schumacher's *Astronomische Nachrichten*, still more complete investigations on barometric measurements will be found. The most handy method with which we are acquainted is due to Mr. Ellis; it will be found described at length in the *Reader* of July 23, 1864.

Heimia (after Dr. Heim, of Berlin). To this genus of *Lythraceæ* belongs *H. salicifolia*, the Hanchinol of the Mexicans, regarded by them as a potent remedy in venereal diseases. It is a small shrub, with willow-like leaves, and yellow flowers in their axils.

Heir (Lat. *heres*). In Law, one who succeeds by descent to lands, tenements, and hereditaments. Strictly speaking, a person is not properly called heir in the lifetime of his ancestor; according to the ancient maxim, *nemo est heres viventis*. (For the rules which govern this succession in England by common law and statute, see *DISENTAIL*.) **Heir-apparent** is he who (by law or custom) must succeed, by descent, to the hereditaments, if he survive the present tenant; as at common law, the eldest son. **Heir-presumptive**, he who stands nearest in succession in the default of an heir-apparent; as an eldest brother where there is no issue. **Heir-at-law**, or **heir-general**, is he who succeeds by descent to lands in fee simple. **Heir-special**, issue in tail claiming by the form of the gift. [*SEE TAIL*.] **Heir by custom**, he who succeeds to lands or tenements by custom; as all the sons by gavelkind. **Heir-male**, i.e. the nearest male in the succession, is not strictly a term of English law, since lands cannot descend in this way; but some dignities are thus limited. A *devisee* is sometimes called *heir by devise*, or *heres factus*. Bastards, aliens, persons attainted of treason and felony, cannot be heirs; but idiots and lunatics may. Things that pass with the land, as conditions and covenants real, goods and chattels annexed to the freehold [*FIXTURES*], and terms of years to attend the inheritance, are in ordinary legal language said to go to the heir: as also **heir-looms**, being such goods and chattels as go by special custom along with the inheritance. In Scottish law, the word *heir* is taken in a larger acceptation, as to personal as well as real property. **Heirs-at-law** are termed in it *heirs whatsoever*. Scottish law recognises several species of heirs: as the heir-active, who has the right of action; heir of line, or lineal heir;

heir of blood, who succeeds to estates to which the donor did not himself succeed by descent; heirs-portioners, in English law coparceners; heir of tailzie (or in tail), and so forth. By the civil

HELIANTHUS

law, heirs are of two kinds—legitimate, or by act of law; and instituted, or by the will of the possessor: the former only answering to those who are properly designated as heirs in our own law, the latter to our *purchasers*. Legitimate are either *heirs of blood*—heirs under the title *unde vir et uxor*, by which, in default of heirs of blood, a husband or wife succeeded to the goods of the deceased spouse (a provision not generally preserved in modern Continental law); and heirs *irregular*—such as the lord to whom an escheat falls, &c. Heirs instituted are of many kinds.

Heir-looms. In Law, such goods and personal chattels as go to the heir along with the realty. The quality of heir-looms is fixed by custom; but the term is commonly applied to pictures, plate, &c., settled so as to go along with a title or estate.

Helen. In Mythology. [*PARIS*.]

Helenine. *Ellecampane Camphor*. A crystalline camphor-like substance, found in the root of *Inula Helenium*, or *Ellecampane*. Its vapour has a peculiar odour somewhat resembling that of *patchouli*. Its chemical formula appears from the analyses of Dumas and Gerhardt to be $C_{21}H_{14}O_5$.

Heliacal (Gr. *ἡλιακός*, *belonging to the sun*). In the ancient Astronomy, a star is said to rise *heliacally* when, after being in conjunction with the sun, and consequently invisible, it rises so soon before the sun as to be visible in the eastern horizon in the morning twilight; and it is said to set *heliacally* when the sun approaches so near to it that it is lost in his light, or ceases to be visible in the western horizon when he has disappeared. At the opposite season of the year the same star rises as the sun sets, and sets as the sun rises; it is then said to rise and set *acronically*. When a star or planet rises and sets at the same instant with the sun, it is said to rise and set *cosmically*. These technical terms occur frequently in the works of Hesiod, and in Ovid's *Fasti*. The ancients fixed the commencement of the seasons by the positions of the stars relatively to the sun at his rising and setting.

Heliades (Gr.). In Greek Mythology, daughters of the Sun, who wept amber tears on the death of Phæthon.

Heliæa (Gr. *Ἡλιάδα*, probably connected with *ἄλλα*, *an assembly*, from *ἀλέω*, *thronged*). In Ancient History, the chief of the ten courts among which the 6,000 Athenian jurymen were distributed, and which on important occasions sometimes contained them all. Before this tribunal were brought causes of consequence to the state and individuals, which did not involve bloodshed. (*Mém. de l'Acad. des Inscrip.* vol. xviii.; Boeckh's *Public Economy of Athens*.)

Helianthus (Gr. *ἥλιος*, *the sun*, and *ἄνθος*, *a flower*). This genus of *Compositæ* yields the well-known Sunflower, *H. annuus*, one of the most showy of large growing annuals; its seeds yield a useful oil in great abundance. Another species is the Jerusalem Artichoke, *H. tuberosus*, a wholesome esculent resembling the potato, and extensively cultivated.

HELICHRYSUM

Helichrysum (Gr. ἥλιος, and χρυσός, gold). The typical genus of the race of Composite flowers which are called Everlastings or Immortelles. These 'everlasting flowers' are in fact the flower-heads of the species of *Helichrysum* and of plants allied to it, which at one time or other have been separated. The ornamental part consists of the involucre scales, which in addition to their dry scarious durable character have acquired colours of more or less brilliancy. The common *H. bracteatum* of gardens has given rise to various everlastings of distinct and showy colours.

Helicoid (Gr. ἡλικοειδής, from ἥλιξ, a curl). There are two surfaces of this name: the *Developable Helicoid* or *screw-surface*, whose generators are the tangents to a common helix; and the *Skew Helicoid*, generated by a line which moves so as always to rest on the helix and cut its axis perpendicularly. The former is simply the developable osculatrix of the helix—a developable surface, therefore, of which the helix is the cuspidal edge; the latter is a conoid having the helix for its directing curve; it is in fact the locus of the principal normals of the helix. The developable helicoid is circumscribed to the skew helicoid, the helix itself being the curve of contact. Every plane perpendicular to the axis of the helix cuts the developable helicoid in the involute of the circular section of the cylinder on which that helix is traced. The developable helicoid is also the *cyclifying surface* of the helix; that is to say, when the surface is unfolded into a plane, the helix becomes a circle.

Heliocentric (Gr. ἥλιος, and κέντρον, centre). The *heliocentric longitude* of a planet is the angle at the sun's centre, formed by the projection of its radius vector on the ecliptic and the straight line drawn from the centre of the sun to the first point of Aries. Similarly the *heliocentric latitude* of a planet is the angle formed by the straight line which joins the centres of both planet and sun, with the plane of the ecliptic. The greatest heliocentric latitude is consequently equal to the inclination of the planet's orbit.

Heliocentric System. In Astronomy, the system which regards the sun as the centre of our solar system. This theory was first propounded by Aristarchus of Samos, and afterwards established by Copernicus. As put forth by him, it needed only Newton's hypothesis of gravitation to complete the system of modern astronomy. (Sir G. C. Lewis, *Astronomy of the Ancients*, chap. iii.)

Heliograph. An instrument devised by Mr. Warren de la Rue for the special object of obtaining photographs of the sun. It may be described as an equatorial telescope with special modifications. The classic heliograph in use at Kew has a tube square in section and larger at the lower end than at the object glass end. The image of the sun, 0.466 inches in diameter at the focus, is enlarged to nearly four inches by means of a secondary object-glass, and this image is received on a photographic plate. The

HELIOSTAT

sun's light is so intense that not only has the aperture to be cut down to two inches, but an instantaneous apparatus of a peculiar construction has to be employed. When the picture is about to be taken, an opening about one-thirtieth of an inch wide flashes across the axis of the secondary object-glass, and the rays from the different parts of the disc pass through it in succession and are depicted on the collodion plate.

Heliography (Gr. ἥλιος, and γράφω, I describe). A general name given to the art of fixing images of objects by means of PHOTOGRAPHY [which see].

Heliometer (Gr. ἥλιος, and μέτρον, measure). A kind of micrometer for measuring the diameters of the sun, moon, and planets, or any small apparent distance between celestial objects. The instrument best known by this name appears to have been proposed or suggested by Mr. Savery (*Phil. Trans.* vol. xlviii.) about the year 1743; but it was first applied by Bouguer in 1747, and has since been improved by Dollond and Fraunhofer. The principle on which the instrument is constructed is as follows: Two object-glasses of the same focal distance, or rather the two halves of a divided object-glass, are placed side by side in the same tube with an apparatus so contrived that the distance between the centres can be increased or diminished at pleasure. In this manner two images of the sun are formed at the focus of the common eye-glass. Thus the circle A A A represents the field of view of the telescope, or the visible circle at the common focus of the two object-glasses and the eye-glass, while the two small circles represent the two images of the sun formed by the two object-glasses.

When the observer proposes to measure the diameter of the sun, the two object-glasses are brought by means of a tangent screw to such a distance from each other that the two images touch in a point T, and the distance between the centres of the two object-glasses, estimated in seconds, gives the distance between B and C the centres of the images; that is, the diameter of the sun. The Oxford instrument is the finest specimen of its class in England; it is admirably described in Nichol's *Cyclop. of the Physical Sciences*. The principle has also been applied to the microscope. [MICROMETER.]

Helios. [PHANTOM.]

Helioscope (Gr. ἥλιος, and σκοπέω, I view). The name given by Scheiner to an instrument of his own invention for observing the sun without hurting the eye. The ordinary method is to place a disc of coloured glass before the eye-piece of the telescope.

Heliostat. An instrument invented by Gravesande for the purpose of obviating in optical experiments the inconvenience arising from the continual change of direction of the solar rays, by reflecting them in the same straight line.

It is easy to conceive a mechanism by which

HELIOTROPE

this object may be accomplished. Suppose a clock to be placed with its dial parallel to the equator, or the axis of the index hands parallel to the axis of the earth; and suppose a rod connected with the extremity of the hour hand to meet the axis produced and make with it the proper angle; then a mirror fixed perpendicularly to the rod will have the motion required.

For a description of the original instrument, see Gravesande's *Phys. Elementa*; but it has been greatly improved by Charles, Malus, &c. (*Journal de l'École Polytechnique*, cahier 16; Biot, *Physique Expérimentale*, tom. ii.) This instrument is now extensively used in connection with the Spectroscope [which see].

Heliotrope (Gr. *ἡλιότροπον*, a plant which turns to the sun). A garden flower of South American origin, known by its peculiar fragrance, which has acquired for it the name of Cherry-pie. The flower-heads offer a good illustration of branching circinate racemes. It can scarcely be called showy, but the plant is highly valued for its odour. *H. peruvianum* is the most popular of the species.

HELIOTROPE. In Geodesy, an instrument used to reflect light to distant stations. Merz and Professor W. A. Miller have both suggested very convenient forms of this instrument.

Helix (Gr. *ἑλῆξ*, a whorl). The name of a Linnean genus of the *Vermes Testacea*, characterised by the entire and crescent-shaped opening of the shell, and forming in the system of Woodward the type of a family of terrestrial and air-breathing Gastropoda, including the genera *Vitrina*, *Bulimus*, *Pupa*, *Succinea*, *Anatoma*, *Streptaxis*, *Sagda*, *Helicella*, *Stenopus*, *Omalonyx*, *Partula*, *Achatina*, *Glandina*, *Spiraxis*, *Achatinella*, *Cylindrella*, *Balea*, *Megaspira*, *Clausilia*, and *Helix* proper, of which our common garden snail, *Helix hortensis*, is an example.

The great vine-snail (*Helix pomatia*, Linn.) formed one of the luxuries of the tables of the ancient Romans, and by peculiar feeding and other treatment was brought to attain an immense size. It is still an article of food in certain cantons in Switzerland and France. Snails do much damage to vegetables in cultivated grounds, biting off pieces of the leaves by means of a semicircular dentated horny plate, which is affixed to the upper lip.

HELIX. In Anatomy, this term is applied to the reflected margin of the external ear.

HELIX. In Architecture, the curling stalks, or volutes, under the flowers in each face of the abacus of the Corinthian capital.

HELIX. In Geometry, a non-plane curve whose tangents are all equally inclined to a fixed right line. The tangents to a helix, therefore, are parallel to the generators of a right cone, having this fixed line for axis. The osculating planes of a helix are also equally inclined to this fixed line, since each contains two consecutive tangents, and is therefore parallel to a tangent plane of the above right cone. The binormals and their parallels, the

HELIX

polar lines of a helix being perpendicular to the osculating planes, are parallel to the generators of the reciprocal of the auxiliary cone under consideration, which reciprocal is obviously also a right cone, so that the polar lines of the primitive helix are inclined to the fixed line at a constant angle, which is the complement of the inclination, to the same line, of the tangents to the original helix. These polar lines, therefore, are tangents to a second helix; in other words, the polar surface of a helix is itself a developable helicoid; the cuspidal edge of this surface, that is to say the second helix itself, is of course the locus of the centres of the osculating spheres of the first helix. The principal normals of a helix are obviously perpendicular to two corresponding generators of our reciprocal cones, and therefore to the plane of these generators, which latter contains the common axis of the cones. Hence the principal normals in question are all perpendicular to the fixed line, in other words parallel to a fixed plane.

The rectifying planes of a helix, being perpendicular to the principal normals, are parallel to the fixed line, and therefore the rectifying surface which they envelope is a cylinder, whose generators, the rectifying lines, are also parallel to that fixed line. When this rectifying surface is an ordinary cylinder of rotation, the helix becomes the common helix, or the curve formed by the thread of an ordinary screw. For the general helix the ratio of the angles $d\tau$ and $d\sigma$ of contact and torsion, and hence also the ratio of the radii ρ and r of curvature and torsion, are constant. This is evident on reflecting that $d\tau$ and $d\sigma$ are the angles between corresponding consecutive generators of our auxiliary reciprocal cones. Conversely the curve is a helix for which r is constant. This was first shown by

Bertrand (*Liouville's Journal*, 1848). For the common helix both ρ and r are constant—a theorem whose converse is also true, as has been shown by Puisseux. The radius of curvature ρ , in fact, is then simply the radius of curvature at the extremity of the minor axis of the elliptical section, in which the right cylinder is cut by the osculating plane; and since all osculating planes are equally inclined to the axis of the cylinder, all such ellipses are equal. The principal normals of the common helix all pass through its axis, and therefore generate a conoidal surface, the skew helicoid, upon which the axis is a line of striction. The locus of the centres of absolute curvature, which for all non-plane curves is situated on the polar developable, coincides with the cuspidal edge of the latter surface in the case of a common helix; so that the loci of centres of absolute and spherical curvature of the helix coincide with a co-axial helix, which has, in common with the original, the same principal normals. The two helices are consequently curves on the same skew helicoid, formed by their common principal normals.

Amongst the numerous interesting properties

HELLADOTHERIUM

of two such *conjugate helices*, the following are worth noting: The tangents of one helix are the polar lines of the other, that is to say the developable osculatrix (*helicoid*) of the one is the polar developable of the other, or the osculating plane of the one is the polar plane of the other; so that their elements adjacent to a common principal normal are perpendicular to one another. These two helices are but special cases of curves described upon the same skew surface, so as to have in common the generators of this surface for principal normals. Two such curves always intercept equal segments upon all generators, and their corresponding osculating planes, through the same generator, enclose a constant angle. Bertrand, Serret, Voizot, and Curtis have published interesting papers on this subject in *Liouville's Journal*, vols. xv. and xvi.

The common helix which passes through three consecutive points of a non-plane curve, and has its axis parallel to the rectifying line of that curve, is called the *osculating helix* of the latter. [*OSCULATING HELIX.*]

(Gr. *ἑλλάς*, *Greece*, and *θηρίον*, *beast*). A fossil mammalian discovered by M. Gaudry near Pikierrri, in Greece. Its similarity to the giraffe at first led Professor Duvernoy to place it under the genus *Camelopardalis*, which it resembled in the proportions of the lower jaw, in the secondary modifications of the grinding teeth, and in the length of the limbs. It was, however, devoid of horns. M. Gaudry and Professor Owen, therefore, erected it into a separate genus. It is found in the old pliocene of France and Greece.

Hellædæmon (Gr. *ἑλλὰς*, *Greece*). The judges in the Olympic games. The judges of the court-martial in the Lacedæmonian army were also known by the same name.

Hellê (Gr.). In Greek Mythology, a daughter of Athamas and sister of Phrixus. She fell from the golden-fleeced ram, and was drowned in the strait which, according to the legend, thus received the name of the Hellespont.

Hellebore (Gr. *ἑλλέβορος*). In Pharmacy, this term is applied to the roots of the black and white hellebore. The root of Black Hellebore (*Helleborus officinalis*), called also *Melampodium*, has a bitterish acrid taste, and is a drastic purge and emetic; the root of the White Hellebore (*Veratrum album*) is similar, but more active in its operation. [*VERATRIA.*] It was formerly used in the cure of gout, and in some maniacal cases where no effect is produced except by very powerful means; but these remedies have now fallen into disuse. The leaves of the *Helleborus fatidus*, or Stinking Hellebore, have also been used to evacuate worms from the intestines; but they are dangerously active.

Helleborus (Gr. *ἑλλέβορος*). Of the Hellebore genus, one of the *Ranunculaceæ*, *H. niger*, well known in gardens as the Christmas Rose and used in medicine, and the Black Hellebore of the ancients, *H. officinalis*, are the most important species. Several others are objects

HELM

of interest in gardens on account of the beauty of their flowers. [*HELLEBORN.*]

Hellenistic (Gr. *ἑλληνιστής*, from *Ἕλλην*, *a Greek*). The name given to the common dialect which prevailed very generally among the Greek writers after the time of Alexander. It was formed, with very slight variations, from the pure Attic of the age preceding its introduction.

Hellenistic. The name given to that dialect of the Grecian language which was used by the Jewish writers. Its peculiarities consisted in the introduction of foreign words very little disguised, but more especially of Oriental metaphors and idioms; but not at all in the inflexions of words, which were the same as in the Hellenic.

Hellenists. The Jews who from their foreign birth or travel used the Greek (Hellenic) language, are distinguished by this name in the Acts of the Apostles. The word is derived, according to a common method of formation in the Greek language, from the verb *ἑλληνίζω*, *to Hellenise*, or adopt the manners of a Greek. There were great numbers of Jews scattered throughout the Roman empire at this period, more especially in the Asiatic and East African provinces, where the Greek was the current language. From their long sojourn in foreign countries they were distinguished from the Hebraists, or native Jews, by the greater liberality of their views with respect to the nature of the promises of the Old Testament. It appears from Acts vi. 1, that these Jews retained the distinctive name of Hellenists after their conversion to Christianity, and that there continued to subsist some jealousy between them and the native Christians.

Helm or **Helmst** (Goth. *hilmr*, Old Norse *hialmr*, Ger. *helm*, Fr. *heaume*). Defensive armour for the head. The armour which particularly guarded the head was known by the general denominations of *headpiece*, *casque*, and *helmet*. Helmets were anciently formed of various materials, but chiefly of skins of beasts, brass, and iron. An open helmet covers only the head, ears, and neck, leaving the face unguarded. Some open helmets have a bar or bars from the forehead to the chin, to guard against the transverse cut of a broadsword; but it affords little defence against the point of a lance or sword. A close helmet entirely covers the head, face, and neck; having on the front perforations for the admission of air, and slits through which the wearer may see the objects around him; this part, which is styled the *visor* (from the French word *viser*, *to take sight*), lifts up by means of a pivot over each ear. Some helmets have a bever (from the Italian *bevere*, *to drink*), which, when closed, covers the mouth and chin, and either lifts up by revolving on the same pivots as the visor, or lets down by means of two or more pivots on each side near the jaws. The use of the bever was to enable the wearer to eat and drink more commodiously than could be done in a helmet with a visor only. The helmets of the Greeks

HELM

and Romans were mostly open, not unlike skull-caps, as formerly worn by our dragoons. Montfaucon says he never saw an ancient helmet with a visor to raise or let down, although he is of opinion that they had those contrivances. It seems as if the Romans, at least those of which Pompey's army was composed at Pharsalia, had open helmets, as Cæsar directed his soldiers to strike them in the face, which order he would not have given if their faces had been covered. The two Grecian helmets in the British Museum have a kind of contrivance to cover the nose. Over the top of the helmet rose an elevated ridge called the *crest*, representing lions or dragons, &c., to make the warrior appear taller and more terrible. For an admirable description of the helmets and helms in use in Europe at various periods, fully illustrated, see Hewitt's *Ancient Armour and Weapons in Europe*.

HELM (Icelandic, *hialmun*, perhaps as being the *helve* or handle by which the ship is managed). The mechanism of the steerage, comprising three distinct portions, the rudder, the tiller, and the wheel; though in small craft the last item is commonly wanting. To put the helm *a-starboard*, is to put the tiller over to the right side; *a-port*, to the left side; *up*, to the weather side; *down*, to the lee side.

Helmet or **Helmet Shells**. [CASSIS.]

Helminthology (Gr. ἕλμινς, *a worm*, and λόγος). The natural history of worms. [INTESTINALIA.]

Helmsman. The man who steers. A good helmsman opposes in time the tendency of the ship to deviate from her course by a small motion, which he relaxes as soon as the effect is felt, thus disturbing her sailing as little as possible. A bad helmsman gives her too much helm, and keeps her perpetually yawing from one side to the other. The steering, therefore, is of the utmost consequence in chase.

Helopidae (Gr. ἑλώψ, or more properly ἑλλώψ). A family of Heteromorous Coleopterans, belonging to the section *Stenelytra*, and including numerous subgenera and species. The typical genus *Helops* is remarkable for having the anterior tarsi of the males dilated. Of this genus there are four British species known, of which the *Helops caraboides* may be found at the roots and under the bark of trees: it presents a lengthened ovate form, a brown colour, a punctured surface, and dusky red antennæ and tarsi.

Helots (Gr. ἐλάτῃαι). In Ancient History, the slaves of the Spartans, consisting originally, in the opinion of some, of the Achæan inhabitants of Laconia, who were subdued by force of arms by the Dorian invaders. The name was, it is said, derived from Helos, a town of Laconia, of which the inhabitants were thus reduced to servitude. To this class were afterwards added the Messenians, who still clung to their native soil after its subjugation by the Spartans. They were employed either as domestic slaves, cultivators

HEMERODROMI

of the land, or in the public works; and though they do not appear to have been treated ordinarily with much severity, yet the recollection of their former state urged them frequently to revolt, while their numbers rendered them so formidable to their masters as to drive the latter to schemes of the most abominable treachery for their repression. (Müller's *Hist. of the Dorians*; Wachsmuth, *Hist. Ant. of the Greeks*, transl. i. 323.)

Helver. A miner's term; the handle of a tool.

Helvine. A mineral occurring in small crystals at Schwartzenberg, in Saxony; it is composed of the silicates of manganese, glucina, and iron.

Helwingiaceæ (Helwingia, the only genus). The characters of this small natural family of Garryal diclinous Exogens lie in their having fasciculate flowers and alternate stipulate leaves. The Japanese use the leaves of *Helwingia ruscifolia* as an esculent.

Hemelytra (Gr. ἡμι, and ἔλντρον, *a sheath*). The name given to the superior wings or wing-covers of Tetrapterous insects, when they are coriaceous at the base and membranous at the extremity; as in the order *Hemiptera*.

Hemeralopia (Gr. ἡμέρα, *the day*, and ὄψ, *the eye*). A peculiarity in the sight, in which persons see in broad daylight, but not in the evening: it is said to be endemic in some parts of Europe, and of the West Indies. The pupil is generally more dilated and less sensible than in healthy eyes. It has been relieved by tonics and gentle stimulants, with the occasional application of blisters behind the ears.

Hemerobaptists (Gr. ἡμέρα, and βαπτίζω, *I baptise*). An ancient sect among the Jews, so called from washing themselves as a religious solemnity every day. It is thought by some that the Christians of Saint John, or Sabians, descend from them.

Hemerobians (Gr. ἡμέρα, and βίος, *life*). A family of Neuropterous insects, of the section called *Planipennes* by Latreille; characterised by having a slender body, which is greatly exceeded in length by the finely reticulated wings. The ova are deposited in clusters, attached each by a long glutinous pedicle to the leaves of various plants; and by some mycologists have been described as fungi. The larvæ of these insects are remarkable for their ravenous habits; and as they feed chiefly on the plant-lice (*Aphides*), are highly beneficial. They subsist on their juices, suck them to death, and with a singular instinct they clothe themselves with the skins of their victims. Of the typical genus *Hemerobius* there are fourteen known British species, of which the *Hem. perla*, Linn., is the most beautiful. It is sometimes called the *golden-eye*; is of a green colour; the wings transparent, and veined with green.

Hemerodromi (Gr. ἡμεροδρόμοι). In the ancient Greek states, couriers, so called from being able to run all day. They served, instead of a system of posts, to carry important news. They were also called Hemeroscopi (ἡμερο-

HEMI

σύνωσις), from being placed on some height in times of danger, to observe anything important that might happen, and give information in the proper quarter.

Hemi (Gr. ἡμι-). A prefix, denoting the half of anything.

Hemiorania (Gr. ἡμι, and κρανιον, *the head*). A pain of one side of the head: it is often intermittent. [HEADACHE.]

Hemidesmus (Gr. ἡμι, and δερμῆς, *a band*). The roots of *H. indicus* are employed in India as a substitute for Sarsaparilla. The genus itself belongs to the *Asclepiadaceæ*.

Hemigamous (Gr. ἡμι, and γάμος, *marriage*). In Botany, a term employed in speaking of grasses, when of two florets in the same spikelet one is neuter and the other unisexual, whether male or female, as in *Isachnum*.

Hemiolegamous (Gr. ἡμι; ὅλος, *entire*; and γάμος). A term employed in speaking of grasses, when in the same spikelet one of two florets is neuter and the other hermaphrodite, as in several species of *Panicum*.

Hemiplopia or **Hemiplopia** (Gr. ἡμι, and ὤψ, *the eye*). A disordered vision, in which objects appear divided.

Hemipinic Acid. Semi-opiatic acid. An acid obtained by the oxidisation of the *opiatic acid*.

Hemiplegia (Gr. ἡμιπληγία, from πλῆσσω, *I strike*). Paralysis of one side of the body.

Hemiptera (Gr. ἡμι, and πτερόν, *a wing*). An order of Haustellate insects, having the wing-covers of a consistence intermediate between the elytra of beetles and the ordinary membranous wings. By Latreille the term is restricted to those insects the wing-covers of which are coriaceous at the base and membranous at the top; the term *Homoptera* being applied to those Fabrician *Hemiptera* of which the elytra are deflected and of uniform consistence throughout.

When the *Hemiptera* quit the egg they present the form of small hexapod larvae, differing but little from the perfect insect save in the absence of wings: before these are acquired the skin is shed several times, during which the larva acquires an increase of general bulk. The pupa is active, and is distinguished by having the wings and elytra concealed in small dorsal cases: the next moulting exhibits the perfect insect with the hemelytra and wings fully developed. The bed-bug (*Cimex lectularius*) and water-boatman (*Notonecta*) are examples of the present order of insects.

Hemisphere (Gr. ἡμισφαίριον). In Geometry, the half of a sphere cut off by any plane passing through the centre. In Astronomy, it is used to designate the half of the terrestrial sphere divided by the equator. Hemisphere also denotes a map or projection of half the terrestrial or celestial sphere on a plane.

Hemispheres. In Anatomy, the two moieties of which the cerebrum is chiefly composed: in man and mammalia they approach the hemispheric form; but in most of the

HEMLOCK

lower vertebrata, where the cranial cavity affords more room for the small brain, both moieties are spherical.

Hemistich (Gr. ἡμιστίχον, from στίχος, *verse*). In Poetry, half a verse. The unfinished verses in Virgil's *Æneid*, concerning which it is not known whether they were purposely left in that state, or are owing to the incompleteness of the poem, are usually called *hemistichs*. The alexandrine, or French hemi-verse, requires a regular pause at the end of the first hemistich.

Hemitrope (Gr. ἡμι, and τρέπω, *I turn*). A term applied by some crystallographers to what are usually called *twin crystals*, from their being generally conceived to result from the cutting, as it were, a crystal in half, and then turning one of the halves half round upon the other. The plane common to the two portions of the crystal is called the *twin plane*. These crystals are often distinguished by the presence of notches or *re-entering angles*.

Hemlock. The *Conium maculatum* of botanists, a common Umbelliferous plant of a peculiar odour, and possessed of narcotic powers. For medical use the leaves should be collected just before the plant flowers; if intended for powder, they should be carefully dried at a temperature not exceeding 212°; if for extract, the juice should be squeezed out by moderate pressure, and evaporated in a water or steam bath to a proper consistency. The *extract of hemlock* is perhaps the best preparation; but as its activity is liable to vary, it should be given with caution. An average dose is five grains. An over-dose produces giddiness, wandering of the mind, dilated pupil, convulsive motions of the muscles of the face, and the other symptoms of this class of poisons. Hemlock is a powerful sedative, and often serviceable as a substitute for or an accompaniment to opium. In allaying morbid irritability of the system attended by any local or general excess of vascular action, as in certain stages of phthisis, in the coughs that are apt to hang about patients who have suffered from pulmonic inflammation, in glandular tumours and unhealthy sores, hemlock is often preferable to opium. It has also been found useful in chronic rheumatism, and occasionally in the treatment of hooping cough. A poultice composed of a mixture of finely powdered fresh hemlock with bread and water, or with extract of hemlock, is applied to allay the pain of irritable ulcers and cancerous sores; it is sometimes singularly effectual, at others it seems inert, and sometimes appears to increase irritation. The virtues of hemlock reside in a peculiar alkaloid, *Conia*, which is represented by the formula $C_{16}H_{15}N$; it is obtained in the form of a volatile oil-like body when the leaves or seeds of hemlock, previously triturated with caustic lime or potash, are carefully distilled with water. Its properties have been investigated by Geiger, and by Christison (*Edinb. Phil. Trans.* 1836). [CONIUM.]

HEMP

Hemp (Ger. *hanf*). The fibres of the bark of the *Cannabis sativa*. It is prepared for spinning in the same way as flax, and is made into strands or yarn for ropes, sailcloth, &c. This plant is supposed to be a native of India, but it has long been naturalised and extensively cultivated in Italy, and many other countries of Europe, particularly Russia and Poland, where it forms an article of primary commercial importance. It is also cultivated to a considerable extent in many parts of America. [CANNABIS.]

Henbane. The *Hyoscyamus niger*, a dingy viscid herb. The expressed juice of the leaves evaporated to the consistency of extract has long been used as a sedative or narcotic. It has a peculiar strong and disagreeable odour, and a nauseous bitterish taste. From two to five grains of the extract of henbane are often found equivalent to about one grain of *opium*, and where the latter disagrees it sometimes produces quiet; in many cases henbane and various forms of *opium* may be combined. Henbane is apt to produce giddiness; but it does not constipate the bowels, and has rather a diuretic tendency. [HYOSCYAMIA.]

Hendecagon (Gr. *ἑνδεκα*, eleven; *γωνία*, angle). A plane rectilinear figure of eleven sides. The area of a regular or equilateral and equiangular hendecagon is, approximately, equal to 9.36564 times that of the square on one of its sides.

Hendecasyllabic (Gr. *ἑνδεκα*, and *συλλαβή*, a syllable). A verse of eleven syllables. The Latin hendecasyllabic, of which the principal specimens left to us are from the pen of Catullus, consists of a spondee, dactyl, and three trochees—

Pascet deliciae meae puellae.

The Italian heroic verse, and those of England and Germany, when increased by the addition of a final short syllable, are iambic hendecasyllables.

The license of adding an eleventh syllable (and sometimes also a twelfth) is more frequently admissible in English dramatic than epic versification.

Henna. A yellow pigment, obtained from *Lawsonia alba* or *inermis*, a plant of the order *Lythraceae*. It is much used throughout the East, for staining the nails of the fingers, and the manes and hoofs of horses.

Henoticon (Gr.). In Ecclesiastical History. The name given to the Edict of Union, issued A.D. 482, by the emperor Zeno, with the design of ending the Monophysite controversy by avoiding all expressions offensive to either party. The success of the measure was very partial. (Milman's *History of Latin Christianity*, book iii. ch. i.)

Henricians. The followers of an Italian monk of the name of Henry, who in the twelfth century traversed the south of France from Lausanne to Toulouse, and met with great success at all the towns at which he halted. He rejected the baptism of infants, and declaimed vehemently against the vices of the

HEPATITIS

clergy. At length his followers were turned against him by the eloquence of St. Bernard, and he died in prison, into which he had been thrown by Eugenius III., in the year 1148. (Milman's *Latin Christianity*, book ix. ch. viii.)

Hensloviaceae (Henslovia, the only genus). A small natural order confined to the single genus *Henslovia*, which Lindley places near to *Hydrangeaceae*; their chief distinction, he observes, consisting in the complete adhesion of the styles into one undivided cylinder. They are tropical plants interesting only to botanists.

Hep or Hip. The fruit of the Dog Rose, *Rosa canina*. [HAWTHORN.]

Hepar (Gr. *ἥπαρ*). This term, signifying liver, was applied by the old chemists to various compounds of sulphur with the metals, having a brown-red or liver colour.

Hepatalgia (Gr. *ἥπαρ*, and *ἄλγος*, pain). A painful affection of the liver.

Hepatic Air (Gr. *ἥπαρ*). Sulphuretted hydrogen, or hydrosulphuric acid, of modern chemistry.

Hepaticæ (Gr. *ἥπαρ*, from the form of the leaves of some of the species). A natural order or principal group of flowerless plants, growing in damp shady places in all temperate climates; in some respects allied to mosses, and in others to lichens. They are of no known importance. The *Marchantiaceae*, *Jungermanniaceae*, and *Ricciaceae* belong to this group: the first known by its valvate capsules placed on the underside of a stalked target-shaped disc; the second by its solitary fruit splitting into four equal valves; and the third by its valveless capsules being sunk in the frond or seated on its surface.

Hepatitis. A mineralogical name of some of the varieties of sulphate of baryta which have a liver colour.

Hepatitis. Inflammation of the liver. The acute or active form is scarcely known in England, it being a disease almost peculiar to warm climates. It is very prevalent in the East Indies. It attacks the lobules of the liver more particularly, and is characterised by violent inflammatory symptoms, and abscess of the organ is by no means an uncommon sequel of the attack. The symptoms are severe pain over the region of the liver and about the right shoulder, inability to lie on the right side, vomiting, dry cough, and hiccups. The treatment consists in purging by neutral salts, and the application of blisters and counter-irritation in other forms. Mercury is used by some in the early stage of the disease, while others of equal experience condemn the practice. Chronic hepatitis is common in this country. The form most commonly met with produces after a time a deposit in the organ, and contraction sometimes follows. 'It is thus that the drunkard's liver, or hobnail liver, as it is familiarly called, is produced. The treatment of this disease consists in the careful administration of alteratives, especially mild mercurials, and the daily exhibition of tonics and neutral salts. Jaundice is an occasional, but by no means a

HEPHAESTUS

necessary accompaniment of hepatitis, and this remark applies to both the acute and chronic forms.

Hephaestus (Gr. Ἥφαιστος). This word, signifying originally brilliance, as of flame, became in Greek mythology the name of the god of fire, who is spoken of as a son of Zeus and Hérè, and who is the husband, in the *Iliad*, of a Charis [CHARITAS], and, in the *Odyssey*, of Aphroditè. The Latins identified him with their god VULCAN [which see].

Heptagon (Gr. ἑπτάγωνος). In Geometry, a plane figure of seven sides. The area of a regular heptagon is equal to the square of one of its sides multiplied into the constant number 3·6339124.

Heptagonal Numbers. Figurate numbers of the second order and fifth class. [FIGURATE NUMBERS]; they are formed by the successive addition of the terms of the arithmetical series 1, 6, 11, 16, &c. whose common difference is 5. Thus the first four heptagonal numbers are 1, 7, 18, 34, and the n^{th} is

$$\frac{n}{2}(5n-3).$$

Heptandrous (Gr. ἑπτά, and ἀντήρ). In Botany, a flower having seven stamens.

Heptarchy (Gr. ἑπτά, and ἀρχή, *I govern*). In English History, the division of England into seven Anglo-Saxon kingdoms, which are represented in most of our histories to have existed at the same time with and independently of each other. The seven kingdoms in question, according to the common divisions, were Kent, Sussex, Wessex, Essex, East Anglia, Mercia, Northumberland. But in point of fact there was no period of history when these seven kingdoms existed together; and, in the constant fluctuations of conquest, fresh subdivisions and unions of territory were continually made by the fortune of war. The sovereign who succeeded in obtaining a temporary supremacy over his neighbour kings generally assumed the title of Bretwalda, or ruler of the Britons, of whom Ælle or Ella, king of Wessex, was the first; but it was afterwards borne by kings both of Kent, East Anglia, and Northumbria. [BRETWALDA.] In 617, Edwin, king of the latter district, appears to have acquired a temporary sovereignty over the whole of England, which was also gained by his nephew Oswald in 634; but after the brother of the latter king, Oswio, no Anglo-Saxon monarch assumed the title of Bretwalda. After the death of the latter, Mercia rose in the scale; and its king, Offa, ruled nearly the whole of the Anglo-Saxon territories in the last half of the eighth century. After his death Egbert, king of the West Saxons, raised his power on the ruins of that of Mercia; and having subdued and rendered tributary the other kingdoms then subsisting, he became, about 830, master of the whole Anglo-Saxon realm, and is reckoned as the eighth Bretwalda or ruler of Britain. With his reign the heptarchy* is usually considered to have ended. (Palgrave's *History of England*; Turner's *Anglo-Saxons*.)

HERALD

Heptyl. A hydrocarbon—C₇H₁₆, constituting the radical of *heptylic* or *amanthylic alcohol*; a compound obtained from fusel oil. Heptyl has not been isolated.

Hera or **Hérè** (Gr.). This word, signifying literally a mistress, reappears apparently in the German *herr*, *lord*. In Greek mythology, the name was confined to the daughter of Cronos and Rhea, and the wife of Zeus, whose name in the Æolic dialect, Ἑρῆς, is only a masculine form of Hérè. In the Homeric poems she is strictly subject to her husband: the idea of Hérè as queen of heaven is of later date. In Latin mythology, Juno takes the place of Hérè. [JUNO.]

Heracleonites. An early sect of heretics belonging to the Gnostics, so called from Heracleon, whose tenets they embraced.

Heracles (Gr. Ἡρακλῆς). In Mythology, the Greek Hercules is represented as the son of Zeus and Alcmena, and as belonging to the race of Perseus. By the counsels of Hera (Juno), his birth was subsequent to that of Eurystheus, whom consequently he had to serve during all his life. Hence the first idea attached to him is that of a mighty being toiling for a mean and worthless master. But the characters under which he appears, range from the heroic to the comic, and even ludicrous type. To the former belongs the beautiful fable of the Sophist Prodicus on the 'Choice of Heracles,' given in Xenophon's *Memorabilia of Socrates*. The burlesque side of his character is exhibited in the *Alcestitis* of Euripides. The Latin god Hercules was at first only a god of boundaries, but was afterwards confused with the Greek Heracles. For the origin of the various myths respecting Heracles, see Max Müller, *Comparative Mythology*; Cox, *Gods and Heroes*; Bréal, *Hercule et Cacus*.

Heracleum (Gr. Ἡράκλειον). A genus of large-growing Umbellifers, of so rapid a growth as to be useful for fodder, and of so noble an aspect as to rank amongst the finest of plants for ornamenting the rougher parts of a garden shrubbery or rockery. The flower-umbels are magnificent. The species have sweet and rather aromatic properties. The most remarkable is *H. giganteum*, which grows ten or twelve feet high, and bears umbels more than a foot across.

Heraclidæ. A general designation for the descendants of Hercules, who, after the death of that hero, are said to have been expelled from the Peloponnesus by Eurystheus, king of Mycenæ. The return of the Heraclidæ, which is placed about 140 years after their expulsion, has been thought to mark the transition from the heroic or fabulous ages to the period of authentic history.

Herald (Gr. ἑρμῆς). An officer of arms, possessed of important functions. The ancient heralds (ἑρμῆες among the Greeks, *feciales* among the Romans) were privileged persons, sacred by superstition as well as by the law of nations. Modern heralds, besides their employment on messages between states and in

matters of public negotiation (in which capacity their services are grown into disuse, or become merely subordinate), acquired a new character from the prevalence of hereditary devices on coats-of-arms early in the middle ages. The multiplicity of these inventions rendered it necessary that there should be certain persons about a court skilled in interpreting or in *blazoning* them according to the rules of the imaginary science to which these fanciful creations were subjected. [HERALDRY.] It became also necessary that they should have a perfect knowledge of the hereditary arms, ensigns armorial, badges of honour, &c. belonging to each family, in order that they might constitute an authority to which appeal might be had in the disputes which frequently arose respecting the rights of individuals to these honourable distinctions. Hence the heralds became, in modern European countries, the depositaries of much of the genealogical science which is conversant in the pedigrees of noble or gentle families. They have also important parts to fulfil on occasions of public solemnity, pageants, installations, nuptials, funerals, &c.

Edward III. was the first English sovereign who created two heraldic kings-at-arms (Surroy and Norroy), whose office was exercised south and north of Trent respectively. Richard II. gave the earl-marshal power to preside in a court of chivalry, assisted by the heralds. But the first heraldic collegiate chapter was held at the siege of Rouen, in 1420. The kings-at-arms were fixed at three, their present number, by Henry VIII. Edward VI. fixed the establishment of heralds on the site of the building which they at present occupy in the city of London. The present Heralds' College (by which name the kings-at-arms, heralds, and pursuivants are incorporated) consists of: 1. Three kings-at-arms—Garter, Clarencieux, and Norroy; of whom the first holds the highest rank. His duties are chiefly to grant supporters to arrange funerals, and present the Order of the Garter to foreign princes. 2. The heralds are six in number; styled Windsor, Chester, Lancaster, Somerset, York, and Richmond; they, with the kings-at-arms, form the collegiate chapter. 3. The four pursuivants (Portcullis, Rouge Dragon, Blue Mantle, and Porte Croix) are junior officers, or probationers, who afterwards succeed to the higher offices. The duties of the officers of the Heralds' College are various, and their powers have been considerable, although curtailed by modern indifference to the purity of their ancient science. They keep the records of the arms, crests, and cognisances of every gentleman, i. e. person entitled to bear them; and they have considerable authority for the purpose of preventing parties from bearing arms to which they have no right. Their title to confer arms, or rather to assign coats-of-arms to persons applying for permission to bear them, is still generally recognised. Heraldic visitations of counties, with a view to collect information on the subject of genealogies and coat-armour, were held as early as the reign of

Henry IV. In 1528, a regular commission was granted for the whole kingdom; and visitations were held at intervals of twenty or thirty years from that time to the beginning of the last century. (*Noble's History of the College of Arms*, 1806.)

Heraldry. The science of conventional distinctions impressed on shields, banners, and other military accoutrements. Heraldry has been divided into personal and national. The first of these treats of bearings belonging to individuals, either in their own or in hereditary right. Devices adopted by champions in the field, and borne on their shields or on their banners, are of very high antiquity. The sculptures on the shields of Achilles and Hercules, in Homer and Hesiod, are rather ornamental than heraldic. But in the drama of *The Seven Chiefs against Thebes*, by Æschylus, we find the cognisances of these renowned leaders distinctly blazoned, as worn by them on their shields, in the same fashion with those of the knights in the middle ages. The Romans do not seem to have had any customary devices for individuals resembling our armorial insignia, with the exception of their distinctive crowns for particular services. The *jus imaginum*, or right of possessing small statues of distinguished individuals of the family, seems to have been their only external hereditary distinction. Early in the middle ages, however, we find abundant notice of cognisances borne by individuals. "These were more especially used in tournaments, where the knights, being clad in complete armour, were unknown to the spectators, except by their banner or shield [BLAZONRY]; and probably it was in the lists of the tournament that the fanciful science of heraldry first found its subject-matter. This science appears to be a compound of inventions collected from very different quarters. The East, the land of allegory and symbol, seems to have contributed many of its most singular devices. Its ordinaries, colours, metals, and gems, are said to be derived from Germany; and German heraldry appears to be a national science, from the circumstance that its terms of art are nearly all of native origin. But the Normans and French undoubtedly cultivated it with the greatest success, and reduced it to its present systematic form. Our English terms of heraldry are, as is well known, derived entirely from the French language, although not wholly from France; as some additions were made to the science by the Norman-English. Hereditary coat-armour, it is said, cannot be traced with certainty to an earlier period than the thirteenth century; but it seems that, in the reign of Henry III., the vocabulary of heraldry was nearly as full and definite as at the present day. National heraldry, or the adoption of distinctive emblems by civil communities, is far more ancient than personal. Badges, we know, were borne on the standards of ancient nations: an eagle was the device of Persia and of Rome, an owl of Athens, &c.; and Turkey and Persia, where personal heraldry is unknown,

HERALDRY

HERALDRY

possess at this day national ensigns of correct heraldic character.

Arms are said, in the heraldic science, to be of dominion or pretension (national); arms of community, belonging to episcopal sees, cities, corporations; arms of patronage, to governors of provinces, &c.; arms of concession, or augmentations of honour, granted by sovereigns to individuals, which in the next generation become hereditary; arms of family, or hereditary arms; arms of alliance, showing the union of families and relations of individuals (marked by various devices termed *differences*, &c.) [DIFFERENCE]; arms of succession, which accompany the possession of certain estates or lordships; and, finally, arms of assumption, taken up by individuals from caprice or vanity, which, although common enough in the present day, are borne in violation of all heraldic laws; or, arms taken up with the permission of the sovereign, through his principal herald (in England, king-at-arms). Armorial bearings were chiefly displayed, in the times of chivalry, on the shield or escutcheon. They were also borne on the pennon, or banner; on sword-hilts, as early as A.D. 1250;

EXPLANATION OF THE PLATE.

I. Lines.

1. Horizontal or straight. 2. Angled. 3. Bevelled. 4. Escartelé. 5. Nowy or Franché. 6. Arched or enarched. 7. Double arched. 8. Wavy or undée. 9. Inverted. 10. Engrailed. 11. Battled-embattled or crenellée. 12. Battled-embattled. 13. Nebuly. 14. Potent. 15. Indented. 16. Dancettée. 17. Dove-tailed. 18. Urdée. 19. Rayonnée or radiant.

II. Points of the Escutcheon, Colours, and Furs.

20. Escutcheon, points of. 21. Or. 22. Argent. 23. Gules. 24. Azure. 25. Sable. 26. Vert. 27. Purpure. 28. Tenne. 29. Sanguine. 30. Ermine. 31. Ermines. 32. Erminois. 33. Pean. 34. Vair. 35. Varry cuppy.

III. Differences or Filiations.

36. (First son) Label of three points. 37. (Second) Crescent. 38. (Third) Mullet. 39. (Fourth) Martlet. 40. (Fifth) Annulet. 41. (Sixth) Fleur-de-lys.

IV. Ordinaries, &c.

42. Chief. 43. Pale (between two annulets). 44. Pallet. 45. Party per pale. 46. Border. 47. Bars. 48. Fess. 49. Bend. 50. Bend sinister. 51. Border. 52. Chevron. 53. Cross. 54. Cross of St. John of Jerusalem or Malta. 55. Cross patonce. 56. Cross moline. 57. Cross of St. Andrew. 58. Crosses humettée. 59. Cross moline in saltire. 60. Cross botonée or trefoil. 61. Cross crosslet, fitchée. 62. Cross flossy. 63. Cross mascle. 64. Cross fitchée. 65. Lozenge, fleury.

V. Miscellaneous Bearings.

66. Lion, statant guardant. 67. Passant. 68. Passant guardant. 69. Rampant. 70. Rampant guardant. 71. Rampant regardant. 72. Sejant. 73. Couchant. 74. Stag at gaze. 75. Stag's head caboshed. 76. Tiger, heraldic. 77. Dragon. 78. Griffin. 79. Dragon's head erased. 80. Wivern. 81. Eagle displayed, with two heads. 82. Eagle's head erased. 83. Water-bouget. 84. Snake, bowed-de-bruised. 85. Quatrefoil. 86. Trefoil. 87. Fleur-de-lys. 88. Clarion or rest. 89. Mulets.

VI. Crowns, Coronets, &c.

90. Crown of England. 91. Coronet of the Prince of Wales. 92. Coronet of a duke. 93. Marquis. 94. Earl. 95. Viscount. 96. Baron. 97. Mitre of a bishop. 98. Eastern or antique coronet. 99. Celestial crown. 100. Crown of Edward I. 101. Mortier, or cap of state. 102. Chapeau, or cap of maintenance. 103. Crown of France. 104. Cardinal's hat. 105. Crown triple, or tiara of the pope.

The principal of these heraldic terms will be found explained under their several titles in the Dictionary.

HERESY

on the mantle or surcoat (hence the phrase coat-of-arms); and, in modern times, on carriages or articles of furniture. The science of heraldry, united as it is with that of family genealogy, was for centuries one of the most favourite literary pursuits (if it can be termed such) among the higher ranks of the community. It has been enriched with much legendary knowledge, and diversified with many fanciful antiquarian theories. It is entitled to respect, not merely on account of its intimate connection with historical knowledge, but also on account of the refinement and curious variety of the learning itself; which, grounded on merely imaginary principles, has been wrought into a system of the minutest accuracy. The best known English work on heraldry is that of Gwillim. The *Encyclopædia Heraldica* of Berry contains many modern additions. See also Edmonson's *Complete Body of Heraldry*, 1780; Dallaway's *Inquiries*, 1783; and the article 'Heraldry' in the *Encyclopædia Metropolitana*, with the various authorities, English and foreign, there referred to.

Herbaceous (Lat. herba). A term used in Botany, in describing the texture of bodies, denoting their being green and cellular, as the tissue of membranous leaves. It is also applied to such perennial plants as lose their stems annually, while their roots remain permanent in the ground.

Herbaria. Collections of dried plants, such as the old botanists called *Horti Sicci* or dry gardens. If well prepared, they are nearly as useful to the botanist as fresh plants; but it is necessary to have some practical skill to be able to employ them advantageously. The largest public herbaria are those of the Museum at Paris, the Imperial collection of Vienna, the Royal collection of Berlin, that of the Royal Gardens, Kew, and that of the late Sir Joseph Banks, now in the British Museum. The herbarium, though an unattractive part of public museums, is very important for many purposes of science.

Hercules (Lat.). In Astronomy, one of the old constellations in the northern hemisphere.

HERCULES. In Mythology. [HERACLES.]

Herderite (so called from Herder, who discovered it). A mineral found in crystals embedded in Fluor at Ehrenfriedensdorf, in Saxony.

Hereditaments (Lat. hæres, an heir). In Law, all things which pass to the heir, being either corporeal (land, with those adjuncts which legally are comprised within that designation), or incorporeal, which are things collateral to land, or issuing out of it, and are enumerated in Blackstone's *Commentaries*, under the heads 'Advowsons, Tithes, Commons, Ways, Offices, Dignities, Franchises, Corodies or Pensions, Annuities, and Rents.'

Heresy (from the Greek *aipeis*, choice, which classical writers apply to the sects of philosophers). This word is now confined to a theological sense, and is defined by Roman Catholic authorities to be the *voluntary* assumption and

HERETOCH

obstinate maintaining of error in matters of faith. They hold all error to be voluntary where the party knowingly deviates from the judgment of the church. The Protestants do not for the most part profess to have any certain standard by which men may judge whether their fellow men be heretical. The statute 1 Eliz., directing the mode of procedure against heretics, declares that no matter or cause shall be adjudged heresy 'but only such as heretofore has been adjudged to be heresy by the authority of the canonical Scriptures, or by some of the first four general councils, or by any other general council wherein the same was declared heresy by the express and plain words of the same canonical Scriptures, or such as hereafter shall be judged or determined to be heresy by the High Court of Parliament, with the assent of the clergy in their convocation.'

For the connection of theories of heresy with the practice of persecution, see Lecky, *History of the Rise and Influence of Rationalism in Europe*.

Heretoch (Ger. *herzog*). The Anglo-Saxon name for the persons who were elected by the folk-mote or full assembly of the people to lead the armies of the kingdom.

Heriot. In Law, originally a tribute given to the lord of the manor on occasion of his engaging in a war (here or *heer geld*). In English law a heriot is a customary service, due for the most part on copyhold tenures, and termed *heriot custom*, being usually the best beast, whether horse, ox, or cow, that the tenant dies possessed of; this is due and payable to the lord of the manor. Some heriots, however, are due on reservation in a grant or lease of land; such are termed *heriot service*. In heriot custom the lord may seize the specific article which he seeks to recover; for heriot service he may either seize or distrain generally on the goods of the tenant on the land.

Herisson (Fr.). In Fortification, a beam armed with iron spikes, and used as a barrier to block up a passage.

Heritable Rights. In Scottish Law, comprehend in general rights to land and things connected with land which pass to the heir; the distinction being in most practical respects identical with that of English law between realty and personality. Heritable jurisdictions were grants of criminal jurisdiction bestowed on great families by the crown. They were abolished after the rebellion of 1745 by the Act 20 Geo. II. c. 43.

Hermæ (Gr. *Ἑρμῆς*). In Grecian Antiquities, small figures or busts of Hermes fixed on quadrangular pedestals on the side and at the crossing of roads. The mutilation of the Hermæ at Athens just before the departure of the Sicilian expedition led to the desertion of the Athenians by Alcibiades. (Thucydides vi. 28, 61 &c.)

Hermaphrodite (Gr. *Ἑρμαφρόδιτος*, the mythical son of Hermes and Aphrodite). An organised body, in which there is either a

HERMAPHRODITE

real or apparent combination of the characteristics of the two sexes. The first is the *true*, the second the *spurious* hermaphrodite. Hermaphrodites are also *natural* or *preternatural*.

The animals in which the organs of the two sexes are naturally combined in the same individual are confined to the invertebrate division, and are most common in the Molluscos and Radiate classes. If the term *hermaphrodite* may be applied to those species which propagate without the concurrence of the sexes, but in which no male organ can be detected, as well as to those in which both male and female organs are present in the same body, then there may be distinguished three kinds of hermaphroditism.

First, The *Cryptandrous*, in which the female or productive organs are alone developed.—Ex.: The cystic Entozoa, the hydrostatic Acalephes, some Polypes, and Sponges.

Second, The *Heautandrous*, in which the male organs are developed, but so disposed as to fecundate the ova of the same individual.—Ex.: The Cirripeds, the Rotifers, the trematode and cestoid Entozoa, and some Acephala, as the *Cyclops*.

Third, The *Allotriandrous*, in which the male organs are so disposed as not to fecundate the ova of the same body, but where the concurrence of two individuals is required, notwithstanding the coexistence in each of the organs of the two sexes.—Ex.: The gastropodous Molluscs, with the exception of the Pectinibranchiate order, and class *Annelida*.

All the other invertebrates, as the Cephalopods and pectinibranchiate Gastropods, most of the acephalous Molluscs, the insects, Arachnids and Crustaceans, the Epizoa and the nematoid Entozoa, the Echinoderms and Medusæ, are, like the vertebrate classes, dioecious, or composed of male and female individuals.

The unnatural hermaphrodites may be divided into those in which the parts peculiar to the two sexes are blended together in different proportions, and the whole body participates of a neutral character, tending towards the male and female as the respective organs predominate; and into those in which the male and female organs occupy respectively separate halves of the body, and impress on each lateral moiety the characteristics of the sex.

This latter and very singular kind of hermaphroditism has hitherto been found only in insects and Crustaceans. In the extracts from the Minute Book of the Linnean Society, printed in the fourteenth volume of their *Transactions*, it is stated that Alexander Macleay, Esq., Sec. L.S., exhibited a curious specimen, showing that two Papilionæ referred to distinct families by Fabricius are in reality the male and female of the same species. This specimen presented the forms and colours of both sexes, divided by a longitudinal line on the body; the right wings and side of the body being as in the male (*Papilio Polycaon*,

HERMAPHRODITE

Fabr.), and the left as in the female (*Papilio Laodocus*, Fabr.).

In Loudon's *Magazine of Natural History* (vol. iv. p. 434), an experienced entomologist, Mr. J. O. Westwood, has given descriptions and figures, not only of dimidiated hermaphrodites (the example is the *Bombyx penii*), but also of quartered hermaphrodites. The latter singular condition is exemplified in a specimen of the *Bombyx castrensis*, in which the right wing, left antenna, and left side of the abdomen are male; the left wing, right antenna, and right side of the abdomen are female: and again in a specimen of stag-beetle (*Lucanus cervus*), in which the left jaw and right elytrum are masculine, and the right jaw and left elytrum feminine.

In most dimidiated hermaphrodites the left side is masculine; but an example of the contrary has been observed in *Sphinx populi*. It is to be regretted that the condition of the internal organs of generation cannot be ascertained in the above singular examples; but this deficiency is in some degree supplied by the results of Dr. Nicholl's dissection of an hermaphrodite lobster (*Phil. Trans.* xxxvi. p. 290), in which a testis was found on that side of the body which exhibited externally the male characteristics, and an ovary on the opposite side.

HERMAPHRODITE. In Botany, when a flower contains both stamens and pistils. Hermaphroditism is the rule, and a separation of sexes the exception, in the structure of flowers.

■ (Gr.). In Greek Mythology, the messenger of the gods. In the Homeric hymn, which gives the myth of Hermes in its most beautiful form, he is the son of Zeus and Maia, who before he is a day old forms a lyre out of a tortoise-shell, and steals the cattle of Phœbus. The enmity caused by this theft between the two gods is appeased by the intervention of Zeus; and Hermes, who gives to Phœbus the power of drawing sweet music from his harp, receives in return the gift of wisdom, and the office of guiding the souls of the dead to their shadowy kingdom. In the mind of the Homeric hymnographer, Hermes appears manifestly as the embodiment of air in motion; as he rises from his cradle, his breath is soft as a summer breeze; but when he exerts his strength, the branches of the forest, rubbed against each other, burst into flame; and hence he is known, like Prometheus, as the giver of fire. In the Vedas, the name occurs in the form Saramā, which is one of the epithets of the Dawn as it comes forth with the fresh morning breeze. The Greek mind fastened apparently on the idea of the breeze, and dwelt on it almost to the exclusion of the idea of morning. The name Saramā is identified with that of Helen; between whom and Hermes a mythical connection is thus established. For an examination of the myths of Hermes, see Max Müller, *Lectures on Language*, second series, p. 462 &c.; Cox, *Tales of Thebes and Argos*, Introduction, p. 45 &c. [MYTHOLOGY.]

HERNIA

Hermetic Art. The imaginary art or science of alchemy; so termed from Hermes Trismegistus, a personage of questionable reality, looked up to by the alchemists as the founder of their art. Some spurious works bearing his name are still extant. [ALCHEMISTRY.]

Hermetic Seal. When a vessel or tube is perfectly closed by fusing its mouth or extremity, it is said to be *hermetically sealed*.

Hermits or **Eremites** (Gr. ἐρημίται). Persons who, in the early ages of Christianity, secluded themselves from the world for devotional purposes, in solitary and desert places (ἐρημὸς), whence their name. [MONACHISM.]

Hermodactyls (perhaps named from Hermus, a river in Asia Minor, and dactylus, a date; or from ἑρμῆς, and δακτύλος, finger; i.e. *the fingers of Hermes*). This term has long been applied to a species of colchicum tuber, probably that of the *Colchicum illyricum*: it is irregularly heart-shaped, and has a furrow upon one side, not unlike the tuber of the *Colchicum autumnale*, now much used in the cure of gout: it is imported from Turkey, and was formerly esteemed as a cathartic. Some of the old writers who are fond of the doctrine of signatures, compare the shape of the hermodactyl to that of a gouty finger, and have recommended its efficacy in that disease.

Hernandiaceæ (Hernandia, one of the genera). A small natural group of arborescent Exogens of the Daphnal alliance, inhabiting the Indian Archipelago and Guinea. They are very near *Thymelacææ*, with which Lindley associates them, differing only in their fibrous drupaceous fruit, lobed cotyledons, and involucre. The leaves, stem, &c. are slightly purgative. The roots of *Hernandia sonora* are antidotes to the Macassar poison, and its juice is a depurative, while the wood of *H. guianensis* makes a good sort of tinder.

Hernia (Lat.). A rupture. The term is generally applied to a tumour arising from a protrusion of part of the intestines or omentum into a sac composed of peritoneum: the groin, or upper and fore part of the thigh, below Poupart's ligament, are common situations. Other viscera may also occasionally form hernial tumours. When the condition of the accident is such that the parts cannot be reduced or returned into the abdominal cavity, the hernia is said to be *incarcerated* or *strangled*. In the latter case the passage through the intestines is interrupted; there is sickness and constipation; and inflammation, and even mortification of the part ensue, unless by an operation the cause of the stricture is removed and the gut returned. What is termed *congenital hernia* is the protrusion of a portion of intestine along with the testicle in its descent through the abdominal ring into the scrotum. Where a rupture exists in early infancy, it is commonly referable to this cause. The surgical history of ruptures is a very complicated and extensive, but highly important subject: it has been ably illustrated by several eminent practitioners.

HERO

Hero (Gr. *ἥρως*). This word probably belongs to the same root with the Latin *herus*, the German *herr*, and may be compared with the Greek *HERA*. In the Homeric poems, it occurs as a title of honour, not only for those who were employed as leaders or fighting men in war (the Danaans and Achæans being collectively called *heroes*), but even for heralds and minstrels, and for the unwarlike Phæaciens. (*Od.* vii. 44.) In the Hesiodic *Theogony*, the heroes are represented as a race of men interposed between the brazen and the iron age [AGE], who fought at the sieges of Troy and Thebes. The exaltation of this race, which even in the *Iliad* (xii. 23) is styled a race of demigods, was completed before the time of Pindar, who makes them a race between gods and men. As so used, the term denoted especially those who were sprung from the union of a divine with a mortal being; as Perseus from that of Zeus with Danaë, and Achilles from that of Thetis with Peleus. But in the later historical writers, the heroes are commonly inferior local deities, as for instance the eponymous heroes of the Attic tribes. Their chapels, termed *Ἡρώα*, although supported by the state, were always distinct from the temples of the national gods.

Hero's Fountain. [Fountain of Hero.]

Herodians. A sect existing among the Jews at the period of our Saviour's preaching. (*Matthew* xvi.; *Mark* viii. 15.) Much doubt exists as to their history and tenets; some commentators, both ancient and modern, imagine that they were fanatics, who regarded Herod the Great as the Messiah; others, that they were a mere political party, attached to the family of Herod; while a third opinion (Bergier, *Dictionnaire de Théologie*) is, that they supported some innovations attempted by Herod in the religious observances of the country by the partial introduction of Pagan usages. (*Milman's History of Christianity*, i. 311.)

Heroic Verse. The verse appropriated to epic or heroic poetry: in Greek and Latin, the hexameter. In English, Italian, and German, the iambic of ten syllables, either with or without the additional short syllable. In French, the iambic of twelve syllables. [EPIC; HEXAMETER.]

Herpes (Gr.). A disease of the skin consisting in the eruption of small aggregated vesicles. Several varieties of herpes are mentioned by systematic writers on skin diseases. A common form is familiarly known as *shingles*. In this, which though not a dangerous is a very troublesome disease, patches of herpetic vesicles extend either quite around or half around the body near the waist. The treatment of herpes in its several forms consists merely in correcting the state of the secretions by alteratives and aperients.

Herpestes (Gr. *ἑρπῆστις*, a creeper). A genus of Viverrine *Carnivora*, comprising the various species of *Ichneumon*. These animals are celebrated for the instinct which Kæmper attributes to them of destroying serpents, and curing themselves from their venomous bites by rubbing

HERPETOLOGY

themselves on the plant named *Ophiorhiza Mungos*. The legends recorded by Herodotus of the connection between the ichneumon and the crocodile are well known. The genus is confined to the Old World.

Herpetology (Gr. *ἑρπετόν*, a reptile, and *λόγος*). The branch of zoological science which specially treats of the class *Reptilia*. This class of animals is characterised by having a heart so constructed as to transmit to the lungs a part only of the circulating mass of blood which it receives from the systenni veins, the remainder being sent again to the body without having been purified in the lungs. There thus results a less amount of reaction of oxygen upon the blood than takes place in Mammalia, and consequently a lower grade of animal heat, and an inferior activity of muscular contraction; but, as the proportion of venous blood transmitted by the heart to the general system varies in different reptiles with the various modifications of the heart, there is a corresponding difference in the manifestation of their vital phenomena.

As reptiles are thus exempt from the office of preserving the temperature of a circulating fluid many degrees warmer than that of the external atmosphere, they have no need of teguments adapted to retain heat; and are accordingly naked, or covered with scales or hard bony plates. Their brain is very small, and without the great commissures. The lungs serve more or less as reservoirs as well as decomposers of the atmospheric air; and thus with a certain degree of independence of the general circulation, the reptiles are enabled to remain much longer under water than either birds or mammalia. Some species indeed have, in addition to their lungs, gills for breathing water, either during their immature state, or throughout life, and thus are truly amphibious. With a cold blood, low respiration, low sensation, and sluggish habits, is associated an extraordinary power of endurance under abstinence or against bodily injury.

Reptiles are either oviparous, or ovoviviparous: they do not incubate. They present a great variety of forms, and constitute altogether a much less natural group than either birds or mammals. The character which Cuvier has assigned to the *Reptilia* would not seem to distinguish them from certain fishes with highly developed air-bladders, without the additional statement that the organ of smell in the class *Reptilia* is situated in a canal communicating both with the cavity of the mouth and the external surface.

Cuvier, after Brongniart, divides the reptiles into four orders, viz. :—

The *Chelonia* (tortoises and turtles); of which the heart has two auricles, and the body is supported on four legs, and enclosed between two plates or shields formed by the ribs and sternum.

The *Sauria* (lizards and crocodiles); of which the heart has two auricles, and the body, supported on four legs, is covered with scales.

HERPETOLOGY

The *Ophidia* (slow-worms and serpents); of which the heart has two auricles, and the body is without legs.

The *Batrachia* (frogs, toads, newts, &c.); of which the heart has but one auricle, and the body is naked, and supported on four, or in a few cases two, legs. Most of these pass, as they advance to maturity, from the condition of a fish breathing by gills to that of a quadruped breathing by lungs. Some, however, never lose their gills.

Such are the characters assigned by Cuvier (in 1829) to his primary divisions of the class *Reptilia*, but they are not a true expression of the organisation of the groups so distinguished. The *Batrachia*, for example, have since been proved to have two auricles, although not so distinct externally as the other reptiles. Some of Cuvier's *Sauria*, again, have two distinct ventricles; whilst the rest have but one, like the *Chelonia* and *Ophidia*. The crocodiles, alligators, and gharrials are the higher organised *Sauria* here referred to; and since they differ also from the *Lacertine Sauria* in having a simple undivided tongue and intromittent organ, and a well-marked modification of the tegumentary system, they deserve to rank as a distinct order, at the head of the class *Reptilia*. This order has been termed by Merrem *Loricata*; for the skin, in fact, instead of being covered by imbricated scales, is strengthened and protected by several rows of flattened and generally elliptical bones, developed between the cuticle and true skin, and often supporting a longitudinal crest; these bones or scutæ are situated chiefly along the back part of the neck, body, and tail.

Another order of *Reptilia* is clearly indicated by the remains of several large or even gigantic species now extinct, in which the extremities were modified to serve as fins on the plan of the paddles of the *Cetaceæ*. These reptiles are chiefly referable to the genera *Ichthyosaurus* and *Plesiosaurus*; they were marine, and of predaceous habits, and constitute the orders *Ichthyopterygia* and *Sauropterygia*.

The *Chelonia* form a third and very natural order.

Those *Saurians* of Cuvier which have a heart composed of a single ventricle and two auricles, a bifid tongue and double intromittent organ, as well as a scaly and generally imbricated covering, form a fourth order of reptiles, to which the term *Squamata* has been given.

The *Ophidia* of Cuvier constitute the fifth order of reptiles. Some naturalists have proposed to unite the serpents with the lizards in the same order, on account of the gradual transition traceable in different genera from one to the other group; but the class of reptiles, by parity of reasoning, ought to be merged in that of fishes; and the naturalists who favour the blending of the tetrapodal with the apodal reptiles seem to forget that an order is a conventional division, a group of convenience, and not an entity circumscribed by nature. To separate the *Batrachia* as a dis-

HERPOLHODE

tinct class from the *Reptilia*, seems to be an error in the opposite extreme. The viviparous four-footed salamander, breathing air by membranous lungs, and circulating blood by a bi-auricular heart, is thus placed in a distinct class from the four-footed lizard, without any essential difference in the pulmonary or sanguiferous systems to warrant the separation; the only differences that can be urged for such a step are a modification of the tegumentary covering, and a greater development and later continuance of the temporary branchial apparatus, of which traces are met with in the embryos of all the air-breathing Vertebrata; and a modification of the reproductive system. The naked integument; the presence of external gills in the young state; the almost simultaneous fecundation, sometimes without intromission, of numerous ova—may be grounds for regarding the *Batrachia* and *Amphibia* as a subclass, or a group somewhat higher than an order; but seem not to warrant their separation from the scaled reptiles as a distinct class, as a group equivalent among Vertebrata to that of birds or mammals. For the subdivisions of the above orders, see *Loricata*; *ENALIOSAURIA*; *CHELONIA*; *SQUAMATA*; *OPHIDIA*; *BATRACHIA*; and also *AMPHIBIA*.

The orders of reptiles *Ganocephala*, *Anomodontia*, *Pterosauria*, *Thecodontia*, *Dinosauria*, and *Labyrinthodontia* are only found in a fossil state.

Herpeton (Gr. *a reptile*). A genus of serpents, allied to *Eryx*, and characterised by two soft prominences covered with scales which are appended to the muzzle. Botanists have a *herpeton* which is a section of *Viola*.

Herpolhode (a word coined from the Gr. *ἔρπω, I wind along*; *ᾠδὴς, an axis*; and *ὁδὸς, a road*). A plane transcendental curve, employed first by Poinot in his graphic representation of the motion of a body around a fixed point. [ROTATION.] It is the locus of the point of contact with a fixed plane of an ellipsoid movable around its fixed centre. The ellipsoidal locus of the points of contact is called the *POLHODE* [see the term], a curve which has obviously two maxima and two minima radii vectores proceeding from the fixed centre *O*. Let us call them *OA*, *OA'* and *OB*, *OB'* respectively, and let *OP* be the perpendicular on the fixed plane of the curve. If we remember that the polhode must be symmetrical with respect to the two rectangular planes *AOA'* and *BOB'*, and consequently that its arcs *AB*, *BA'*, *A'B'*, *B'A* are equal and similar, it will be evident that the herpolhode must undulate symmetrically between two concentric circles described around *P* as centre, with the radii $\sqrt{OA^2 - OP^2}$ and $\sqrt{OB^2 - OP^2}$ respectively, which circles it will touch alternately at equidistant points *a*, *b*, *a'*, *b'*, &c. The herpolhode is, in general, an unclosed curve; should the angle $\alpha P b$, however, be commensurable with a right angle, it will be closed. When the distance *OP* from the

HERRING

fixed point to the fixed plane becomes equal to the mean semi-axis of the ellipsoid, the polhode becomes an ellipse having the mean axis for minor axis, so that $OP=OB=b$. The circle b, b', b'' , &c., now degenerates to a point, which the herpolhode, now a spiral, approaches symmetrically, its polar equation being

$$r(\cos\theta + e^{-2\theta}) = 2nb,$$

where b is the mean axis of the ellipsoid, and $nb = \sqrt{OA^2 - b^2}$. When the ellipsoid is one of revolution, the herpolhode, like the polhode, becomes a circle. The herpolhode is fully investigated in Poinso's classic *Théorie Nouvelle de la Rotation des Corps*, Paris 1852.

Herring (Ger. *heer*, an army, in reference to the great numbers in which the fishes so called appear, at stated seasons, along our coasts). This name is commonly applied to two distinct but closely allied species of the genus *Clupea*, Linnæus: to the one Mr. Yarrell restricts the name *Clupea Harengus*; the other is denominated *Clupea Leachii*, in commemoration of the excellent naturalist who first appears to have been aware that our coast produced a second species of herring.

The genus *Clupea* is so nearly allied to the genus *Salmo* that they are both included in the same natural family, under the name of *Halecoidea*, by M. Agassiz; the principal external difference consists in the absence of the small adipose dorsal fin in the *Clupea*. But in the clupeoids, as in the salmon tribe, the upper maxillary as well as the intermaxillary bones enter into the formation of the mouth, and are both armed with teeth; the body is always covered with numerous scales; and, in the greater number of the herring tribe, there is an air-bladder, and the duodenum is complicated with many *cæca*, or pyloric appendages.

The annual migration of the herring is not, as has been described, from one latitude to another, but simply from a deeper to a shallower part of the ocean. The common species, impelled by the stimulus of the increasing burden of milt or roe, quits the deeper recesses of the ocean, where it has passed the winter and spring months, and approaches the shallower water near the coasts, where the ova may be deposited, and impregnated with the requisite amount of heat, light, and oxygen for their development.

The common herring visits different parts of our coast in autumn, generally earlier on the southern than on the northern localities, and deposits its ova and spawn towards the end of October. In this state the fish are termed *shotten herring*, and they retire from the shore into deep water.

Leach's herring has a different season of sexual migration. 'It is found,' says Mr. Yarrell, 'heavy with roe at the end of January, which it does not deposit till the middle of February. Its length is not more than seven inches and a half, and its depth near two inches.'

During the long period in which the herring

HERTHA

stays in deep water, the shoals occasionally travel so far as to appear at the next season of oviposition at a different part of the coast from that where they were previously abundant. Hence the herring has been described as a most capricious fish; and it is truly said, 'that there is scarcely a fishing station round the British Islands that has not experienced in the visits of this fish the greatest variations, both as to time and quantity, without any accountable reason.'

Herrings are taken in drift nets, and during the night. The stretching of the nets in the daytime is forbidden, as it is supposed that the practice would alarm and drive away the shoal. The darkest nights, and a breeze that ruffles the surface of the water, are the circumstances which most favour the capture of the herring.

Herringbone. The name given to strutting placed between thin joists, consisting of pieces of small scantling that go from the top of one to the bottom of another joist, and respectively otherwise; it is introduced for the purpose of increasing the lateral stiffness of the joists. The same term is also applied to paving, or bricks, laid contrariwise from the same meeting line, either horizontal or vertical.

Herrnhut (Ger. *the Lord's guard*). An establishment in Upper Sasia, comprising, it is said, at present 120 houses, with 1,500 inhabitants, and founded by a few Moravians about the year 1722, under the patronage of Count Zinzendorf. The principles of the society thus formed are seclusion from the world, the enjoyment of a contemplative life, and the possession of all goods in common. Its members are bound together, under the title of Moravian Brethren, by strict laws and observances. Accusations have been thrown out against them of indulging, in their retirement, in many licentious practices; but it is certain that their industry supplies many of the markets of Germany with various useful and ornamental articles of handiwork; that their zeal has prompted them to establish affiliated societies in many parts of Europe and America; and that in religious matters they are neither extravagant themselves, nor intolerant of others.

Herschel. [URANUS.]

Herschellite. A hydrous silicate of alumina, soda and potash, found in colourless hexagonal crystals, at Pelagonia and Aci Reale in Sicily. Named in honour of Sir J. F. Herschel.

Hesse, Hesseille (Fr.). In Fortification, a lattice or portcullis armed with spikes, used to close a gateway.

Hertha (sometimes written Aërtha, Aërtha, and Eorthe). In Mythology, the name of a chief divinity of the ancient German and Scandinavian nations. She was worshipped under a variety of names, of which the chief were analogous to those of Terra, Rhea, Cybele, and Ops, among the Greeks and Romans. Long before the Christian era the knowledge of Hertha appears to have been extended over a great portion of Northern Europe; for Tacitus

HESPERIA

(*Germ. xl.*) speaks of the wonderful unanimity which tribes that had no other feature in common displayed in worshipping this goddess, whom he designates *Herthus*, or *Mother Earth*. Her chief sanctuary was situated, according to the same writer, in a sacred grove in an island of the ocean, which, by some writers, has been supposed to be Riga, and by others Zetland or Heligoland; but no modern researches have been able accurately to fix its locality. Much curious information upon this subject is to be found in Grimm's *Deutsche Mythologie*, chap. x.

Hesperia. A genus of butterflies, now the type of a family, including several subgenera, to some of which belong the British species, eight or ten in number.

Hesperides (Gr. from *ἑσπερος*, the evening). In Greek Mythology, the guardians of the golden apples given to Hera (Juno) on the day of her marriage. The legends about them vary indefinitely in detail, some making them four, others seven in number, some speaking of them as children of Night or Erebus, some of Atlas, some of Hesperus, some of Zeus, &c. Their abode was held to be a garden in the western part of Africa, where the dragon Ladon helped them to watch the sacred fruit.

Hesperidine. An insipid white crystalline substance obtained from the soft spongy part of orange and lemon rind. It has also been called Aurantine.

Hesperidium. In Botany, a many-celled, few-seeded, superior, indehiscent fruit, covered by a spongy separable rind; the cells easily separable from each other, and containing a mass of pulp, in which the seeds are embedded—example, the orange.

Hessian. The Hessian of a quantic is best defined as the Jacobian of the system of first derived functions of that quantic. [JACOBIAN.] The name Hessian was proposed by Sylvester (*Phil. Trans.* 1853) in honour of Hesse, the discoverer of the function. The Hessian of the ternary quantic u is

$$H = \begin{vmatrix} \frac{\partial^2 u}{\partial x^2} & \frac{\partial^2 u}{\partial x \partial y} & \frac{\partial^2 u}{\partial x \partial z} \\ \frac{\partial^2 u}{\partial y \partial x} & \frac{\partial^2 u}{\partial y^2} & \frac{\partial^2 u}{\partial y \partial z} \\ \frac{\partial^2 u}{\partial z \partial x} & \frac{\partial^2 u}{\partial z \partial y} & \frac{\partial^2 u}{\partial z^2} \end{vmatrix}$$

In general we may say that the Hessian of an m -ary n -ic is a symmetrical functional determinant of the m^{th} order whose constituents are the several second derived functions of the given quantic. It is always a covariant of the quantic of the m^{th} order in the coefficients, and of the $m(n-2)^{th}$ in the variables; it is, in fact, the discriminant of the second emanant

$$\left(x' \frac{\partial}{\partial x} + y' \frac{\partial}{\partial y} + z' \frac{\partial}{\partial z} + \&c. \dots \right)^2 u$$

of the quantic, this emanant being regarded as a quadric in which the original facients x, y, z, \dots are regarded as constants. [DISCRIMINANT and EMANANT.]

HETÆRIA

In geometry, the Hessian of a ternary quantic when equated to zero, represents the important curve, known also as the Hessian of that which is represented by equating to zero the quantic itself. The Hessian of any curve of the n^{th} order is a curve of the $3(n-2)^{th}$ order, which not only passes through all the double points of the original, but has itself double points which coincide with the latter.

Now the second emanant represents the polar quadric of any point with respect to the given curve, so that from what precedes the Hessian may be regarded as the locus of all points whose polar quadrics break up into pairs of right lines, whence it follows that the Hessian also passes through the points of inflexion of the original curve. (Salmon's *Higher Plane Curves*.)

It is scarcely necessary to observe that the Hessian of a ternary quadric no longer represents a curve; it is simply the discriminant of the quadric, and, equated to zero, expresses the condition under which the quadric in question will break up into a pair of right lines.

The Hessian of a quaternary n -ic, equated to zero, represents a surface of the $4(n-2)^{th}$ order, which is called the Hessian of the surface represented by equating the quantic to zero. The relation of the Hessian to the original surface is also very important. It passes through the double, as well as through the parabolic points of the latter. [INDICATRIX.] Every point of a developable surface being parabolic, its Hessian consists of the surface itself together with a second one of the order $3n-8$, to which the name *Pro-Hessian* has been given. The properties of the Hessian are examined at some length in Salmon's *An. Geom. of Three Dimensions*, to which work the reader must be referred for further information on this subject.

Hestia. [Vesta.]

Hesychasts (Gr. *ἡσυχαστής*, from *ἡσυχία*, quiet). In Ecclesiastical History, a singular class of fanatics, who were established in the fifteenth century in some of the Greek monasteries of Mount Athos. These Quietists pretended to have attained a perfect interior life of devotional repose by intense contemplation. One of their maxims, apparently derived from some of the strange practices of the Indian ascetics, directs the disciple to 'raise his spirit above all vain and transient things, repose his head on his breast, and turn his eyes with his whole power of meditation upon his navel.' Hence these visionaries derived the nickname of 'Ομφαλόβρυχοι (Cantacuzenus ii. 38), or Umbilicarii: they were also termed Thaborites, from their notion respecting a divine light inhabiting the heart of the devotee. (Gibbon's *Roman Empire*, ch. lxiii.; Waddington's *History of the Church*, chap. xxvi.)

Heteria (Gr. *ἑταῖρα*, from *ἑταῖρος*, a companion). This word is frequently used by classical writers to signify an association of any kind; thus the fraternities of the early Christians are called Heteriæ. In modern times two celebrated associations among the modern Greeks have assumed the name.

HETEPOSITE

The first was the Heteria of the Philomusoi, or Friends of the Muses; a society formed for the purposes of education, founded (it is said) by Capodistrias, about 1814: it established schools at Athens and elsewhere, and numbered at one time 80,000 associates. It was dissolved in 1821; but renewed in 1824, when Athens was in the hands of the Greeks. The more famous political Heteria owes its foundation to the celebrated Rigas, who died in 1798. It was renewed about 1816, extended its ramifications through all Greece, and produced the Greek revolution, begun by Ypsilanti in 1821. (Finlay's *History of the Greek Revolution*, 1861.)

Heteposite. A native phosphate of iron and manganese.

Hetero- (Gr. *ἕτερος*, the other, one of two). As a prefix, or in composition, this term usually indicates difference; in opposition to the prefix *homo-*, which indicates resemblance.

Heteroccephalus (Gr. *ἕτερος*, and *κεφαλή*, a head). In Botany, when in composite plants some are male and others female in the individual.

Hetero- (Gr. *ἕτερος*, and *χρῶμα*, colour). In Botany, when in a flower-head the florets of the centre or disc are different in colour from those of the circumference or ray.

Heterodox (Gr. *ἑτεροδοξος*, of another opinion). A person who holds opinions different from some standard with which they are compared, is opposed in theological language to *orthodox*, one who holds the right opinion. The standard of orthodoxy in Christian belief by which opinions must be tried, resides, humanly speaking, in the judgment of each particular sect of believers. Each section of opinion consequently regards itself as orthodox; but in this country, that which is commonly called the High Church party, professing to hold more strictly by ancient creeds and formularies, is most in the habit of assuming the appellation. [H v.]

Heterogamous (Gr. *ἕτερος*, and *γάμος*, marriage). In Grasses, when the arrangement of the sexes is different in different spikelets from the same root, as in *Andropogon*: in Composite plants, where the florets are of different sexes in the same flower-head.

Heterogeneous Attraction. [AFFINITY, CHEMICAL.]

Heterogeneous Quantities. In Mathematics, quantities incapable of being compared together in respect of magnitude, as lines and surfaces, surfaces and solids, &c.

Heterogenesis (Gr. *ἕτερος*, and *γένεσις*, birth). This term is defined by Pouchet as the production of a new animal without the intervention of parents, all its primordial elements being drawn from surrounding nature. It is analogous to spontaneous generation, by which process the ultimate structures of animals were supposed to have been derived originally from nothing. This theory was advocated by Oken, and by many of the Latin and Greek writers. Pouchet narrates the conditions under which he considers that

HEULANDITE

animals have been spontaneously produced, in his work *Hétérogenie* (8vo. Paris 1859), in which he details the care which he took to eliminate all substances, e.g. putrescible bodies, water, and air, which might act as vehicles of organic germs. His experiments are unquestionably the most conclusive which have ever been made on the subject.

Heterogyna (Gr. *ἕτερος*, and *γυνή*). A tribe of Aculeate Hymenoptera, in which the females are of different kinds; one fertile, the other infertile, called *neuters*, as the ants, *Formicidæ* and *Mutillidæ* [see those words].

Heteromerans (Gr. *ἕτερος*, and *μῦρος*, a leg). In Zoology, a term signifying that the legs have a different structure from one another. The Coleopterous insects are so called which have five joints in the tarsus of the first and second pairs of legs, and only four joints in the tarsus of the third pair. Latreille divides this somewhat artificial section into four groups.

1. *Melasomes*, having the wing-covers hard, wings generally wanting, claws simple, and maxillæ with a hook.—Ex.: *Pimeliide*, *Blaspide*, *Tenebrionide*.

2. *Taxicornes*, having the wing-covers hard, wings present, antennæ perfoliate or clavate, claws simple, maxillæ without a hook.—Ex.: *Diaperide*, *Cossyphide*.

3. *Stenelytres*, having the wing-covers hard and contracted posteriorly, wings present, antennæ simple, claws simple or toothed.—Ex.: *Helopide*, *Cistellide*, &c.

4. *Trachelides*, having the wing-covers flexible, wings present, head inserted upon a neck, claws bifid.—Ex.: *Meloe*, *Mordella*, *Horia*, *Lagria*, &c.

Heteropods (Gr. *ἕτερος*, and *πούς*, foot). The name of an order of Gastropods, comprehending those which have the foot compressed, and in the form of a thin vertical fin; as in the *Carinaria*.

Heteropterans (Gr. *ἕτερος*, and *πτερον*, a wing). The name of a section of Hemipterans, comprehending those in which the hemelytra terminate abruptly by a membranous appendage.

Heteroscians (Gr. *ἑτεροσκίος*, from *ἕτερος*, and *σκία*, shadow). An epithet applied by the ancient geographers to the inhabitants of the two temperate zones, because their shadows at midday are always projected in opposite directions in respect of each other; in one case to the north, and in the other to the south.

Heterotropical (Gr. *ἕτερος*, and *τροπή*, I turn). A term applied to the embryo of a seed when the former lies across the latter, that is to say, neither pointing to its base nor apex.

Metman (another form of Hauptmann or headman). A Cossack title for the commander of a regiment. [COSSACKS.]

Heuchera (after J. H. Heucher). This genus of herbaceous *Saxifragaceæ* yields the astringent Alum-root, which is the root of *H. americana*.

Heulandite. A mineral formerly classed with the zeolites found in the basalt of the

HEWN STONE

Giant's Causeway and elsewhere: it is a silicate of alumina and lime, named after the mineralogist, Heuland.

Hewn Stone. That kind of stone which is employed after the whole face has been worked; it differs from block stone in the superior quality of the work upon the surface.

Hexachord (Gr. ἑξ, and χορδή). In Music, a progression of six notes, to which Guido attached the syllables *ut, re, mi, fa, sol, la*. The hexachord is also called a *sixth*; and is twofold, greater and less. The former is composed of two greater, two less tones, and one greater semitone, making five intervals; the latter of two greater tones, one lesser and two greater semitones.

Hexagon (Gr. ἑξάγωνος, *six-cornered*). In Geometry, a plane figure bounded by six straight lines. When these are equal, the hexagon is regular. The side of a regular hexagon is equal to the radius of its circumscribing circle, a property which has numerous useful applications. The area is equal to the square of the side multiplied into the constant number 2.598076; that is, into three times half the tangent of 60°.

Hexagonal Numbers. *Figurate numbers* of the second order and fourth class; they represent the successive sums of an arithmetical series whose first term is 1 and common difference 4. The n^{th} hexagonal number, therefore, is $n(2n-1)$.

Hexahedron. In Geometry, a solid bounded by six planes. A parallelepiped is a hexahedron whose opposite faces are parallel. The cube, or *regular hexahedron*, is one of the five regular solids, having six equal square faces, twelve equal edges, and eight solid angles, each formed by the meeting of three plane right angles.

Hexameter (Gr. ἑξάμετρος, from ἑξ, and μέτρον, *measure*). The most important species of verse used by the Greeks and Romans. It consisted of six feet, either dactyls or spondee, which might be used indifferently in any part of the verse; with the two exceptions, that the last foot must be a spondee, and the last but one a dactyl. In some instances a spondee is introduced into the fifth foot, or last but one, the line being then termed *spondaic*. But in such cases the fourth foot must be a dactyl. [Foot; CÆSURA.] In modern times, several poets of France, England, and Germany have attempted to introduce this measure into the language of their respective countries. It has been cultivated in Germany with great success, as the *Hermann and Dorothea* of Goethe, and many other examples that might be cited, abundantly prove. The spirit of the measure has been admirably caught by Voss in his translation of Homer, and by Eberhard in his poem called *Hannchen und die Kuchlein*.

The success of English poems in hexameter verse, whether original or translations, is more doubtful. Recent translators of Homer, in particular, appear to regard the hexameter as a metre not congenial to the English language,

HIBISCUS

which almost invariably imparts to it a jingling anapestic character. (For the controversy on the subject, see Professor Arnold's *Lectures on Translating Homer*; *Edinburgh Review*, April 1863, p. 360; Lord Derby's *Iliad*, Preface.)

Hexandrous (Gr. ἑξ, and ἀνδρ, *a male*). In Botany, a flower having six stamens.

Hexapla (Gr.). The combination of six versions of the Old Testament by Origen is so called: viz. the Septuagint, those of Aquila, Theodotion, Symmachus, one found at Jericho, and another at Nicopolis. [BIBLICAL HISTORY, &c.]

Hexapods (Gr. ἑξ, and πούς, *a foot*). A name applied by Mr. Kirby to a suborder of Apterus insects, including those which have not more than six legs.

Hexastyle (Gr. ἑξάστυλος). In Architecture, temples or buildings with six columns in front.

Hexyl. A hydrocarbon = C_6H_{12} . It is a colourless oily liquid, insoluble in water, but soluble in alcohol and ether.

Hiatus (Lat. *a yawning or gap*). This word has passed into several modern languages. In Diplomatics and Bibliography, it signifies a deficiency in the text of an author, as from a passage erased, worn out, &c. In Grammar and Prosody, it signifies properly the occurrence of a final vowel, followed immediately by the initial vowel of another word, without the suppression of either by an apostrophe. This, in Greek and Latin poetry, was only admissible in certain cases; as where, in Greek, a final long vowel is succeeded by an initial short vowel, and becomes sometimes short by position; or, in Latin, where the *cæsura* [CÆSURA] gave an additional force to the first vowel, as in the celebrated line,

Ter sunt conati imponere Pelio Œtæam,

which affords an instance of both, the first hiatus being occasioned by the *cæsura*; the second, an imitation of the Greek prosody. In French the hiatus is carefully avoided; in English less so, although by the more accurate poets it is still regarded as a blemish, except in some instances where a long vowel is followed by a short one. The worst species of hiatus is where the same vowel sound is repeated.

Hibernation. [HIBERNATION.]

Hibiscus (Lat. *hibiscum*, Gr. ἱβίσκος). A genus of very handsome plants, belonging to the Malvaceous order, with unusually large and showy flowers. They are numerous in the tropics, where they generally form fine trees; but some of the species are only annual. Of the latter, *H. Trionum* is a commonly cultivated plant, known in the seed-shops under the name Bladder Ketmia. Very few of the species are of any interest. *H. cannabinus*, called Indian Hemp, yields a fibre-like jute. *H. syriacus* is the *Athæa frutes* of shrubberies; *H. Abelmoschus* yields the musk-seed of pharmacy; and *H. esculentus*, the *Gobbo* or *Ochro* of the tropics, bears seed-vessels abounding so much in mucilage as to be a common ingredient in the soups of the hotter climates of the world. These are

now often referred to the genus *Abelmoschus*. *H. Rosa sinensis*, a Chinese plant, is remarkable for the property possessed by its flowers of dyeing black.

Hiccup or **Hiccough** (Lat. singultus). A spasmodic affection of the diaphragm caused sympathetically by irritation of structures supplied by nerves communicating with the phrenic or great diaphragmatic nerve. Hiccup is a common symptom of dyspepsia, hysteria, and various nervous disorders. It is often observed in abdominal diseases when terminating fatally, and is especially a symptom in some forms of hernia.

Hidalgo. A Spanish nobleman of the lower class; literally *hijo d'algo*, son of somebody; in Portuguese, *fidalgo*. It is absurdly derived by B. St. Vincent from *hijo de gato*. The title is now obsolete.

Hide (Ger. haut). This term is limited in commerce to the strong and thick skin of the horse, ox, and other large animals.

Hide of Land. [HYDE.]

Hide-bound. In Arboriculture, applied to trees in which the bark does not swell freely in proportion to the growth of the tree.

Hiera Plora (Gr. *tepos*, sacred, and *πικρός*, bitter). A compound of aloes and canella bark made into pills or into an electuary with honey.

Hierarchy (Gr. *ἱεραρχία*, from *tepos*, and *ἄρχω*, I rule). A general term, comprehending the various ranks and orders of the sacred ministry, whether of angels, according to an ancient opinion, or of the pastors of the church of God upon earth. For the formation of the celestial hierarchy, see Milman's *Latin Christianity*, book xiv. chap. ii.

Hieratic Character. [HIEROGLYPHICS.]

Hieroglyphics (Gr. *ἱερογλυφικός*, from *tepos*, sacred, and *γλύφω*, I engrave). Sculpture-writing or picture-writing; i.e. the expression of a series of ideas by representations of visible objects. The name is more peculiarly applied to a species of writing in use among the ancient Egyptians. [ALPHABET.] According to the system of Champollion, the hieroglyphical writing of the Egyptians consists of three different species of characters: 1. The hieroglyphic, properly so called, in which the representation of the object conveys the idea of the object itself; either entire, or in an abridged form. Many words were thus expressed, chiefly those denoting common visible objects. These are termed by Champollion *figurative*, and divided into *figurative proper*, *figurative conventional*, and *figurative abridged*. 2. The second class of hieroglyphical characters consists of those which represent ideas by images of visible objects, used as symbols; and these are generally employed in the expression of abstract ideas or complex modes: as, a *tumult*, represented by a man throwing arrows; *adoration*, by a censer containing incense, &c. In some of these the connection between the type and antitype is obvious; in others, it depends on associations which are not understood by us, and consequently cannot be traced. These

characters are what the Greeks more peculiarly termed hieroglyphics: they are called by Champollion *symbolical*. 3. The third class consists of *phonetic characters*, in which the sign represents not an object but a sound. This, according to Champollion, was effected by the following device. The figure representing a letter was the likeness of some animal or other object of which the name began with that letter. Thus Champollion has constructed an alphabet of initials, in which the letter A is represented by an eagle, the initial letter of the Egyptian word *eagle* (Ahorn) being A; and so forth. Twenty-nine elementary sounds were thus represented. But the writer was not confined to the use of one representative of a letter only. At first sight it would appear that all objects, the initial of whose name was a particular letter, might be used to express that letter; but custom seems to have applied only a certain number of objects to this use: some letters have eighteen or nineteen known representatives, others six or seven. The honour of the recent progress made in the explanation of hieroglyphical writing is divided between the English Orientalist, Dr. Young, and the Frenchman Champollion. (*Edinburgh Review*, July 1862, p. 102.) Much progress has been made of late years in the further elucidation of the subject by Dr. Hincks, Sir H. Rawlinson, Lepsius, and Bunsen (*Egypt's Place in History*). Besides the hieroglyphic character, the Egyptians used the *hieratic* and *demotic*, which were, both of them, conversions of the hieroglyphic into a kind of current hand: the latter nearly alphabetical. The most civilised people of America, the Mexicans, at the time of the Spanish conquest, had advanced as far as the discovery of hieroglyphical or picture writing, although they did not possess a written alphabet. The Chinese writing was, originally, wholly ideographic; i.e. expressing ideas by symbols (answering to the second class of Egyptian hieroglyphics, with some admixture of the first). But in process of time the greater part of the characters have become simply phonetic. (See especially the art. 'Hieroglyphics' in the *Ency. Brit.*; also Jablonski, *Pantheon Egyptiacum*; Seyffarth, *Rudimenta Hieroglyphices*, 1825; Sir G. C. Lewis, *Astronomy of the Ancients*, ch. vi.)

Hierogrammatists (Gr. *ἱερογραμματεῖς*, a sacred scribe). The name given to certain Egyptian priests whose duty it was to keep the sacred records, to teach the ritual, and to insure its accurate observance.

Hieromancy (Gr. *ἱερομαντία*). The art of divination from the appearances presented by the victims offered in ancient sacrifices.

Hieromnemon (Gr. *ἱερομνήμων*, an observer of sacrifices). In Ancient History, the title of one of the two deputies sent to the meetings of the Amphictyonic Council by each tribe composing that confederacy. His office was, as the name imports, to superintend the religious rites on the occasion.

Hieronymites or Jeronymites. An order so named from its patron St. Jerome. It originated in Spain, and comprehended religious of both sexes. The Hieronymite convents are usually in mountainous and solitary places, in imitation of the retreat of St. Jerome to his hermitage at Bethlehem.

Hierophantes (Gr. from *tepos*, and *paluo*, *I show*). The title of the priest who initiated candidates at the Eleusinian Mysteries. He was necessarily a citizen of Athens, and held the office, which was regarded as one of high religious importance, for his life. (Meursius *On the Eleus. Mysteries*; Potter's *Grecian Antiquities*, vol. i.; *Mém. de l'Acad. des Inscr.* vol. xxi.)

High Church. In English History, an epithet usually applied to those opinions which tend to exalt the ecclesiastical power, and to the parties which embrace them. According to Burnet (*Time*, vol. ii. p. 249), the term *high church party* began to be used about the year 1700. Those who belonged to it were at that time considered to be unfriendly to the settlement of the nation at the Revolution, and disposed to Jacobite principles. Under Queen Anne, high church principles were for a short time in the ascendancy; but after the accession of George I., in 1716, it is difficult to point out any political party which has seriously embraced them. But in matters relating to the discipline of the church itself, a *high church* and a *low church* party, the former attaching more and the latter less value to ecclesiastical dignities and ordinances, have always existed in the establishment of England.

High Commission, Court of. In English History, this court was erected by 1 Eliz. c. 1 as an ecclesiastical tribunal, without power to fine or imprison. The commissioners seem, however, to have committed various arbitrary acts towards the end of that queen's reign. One of their warrants was declared of no authority in 42 Eliz. Under Charles I. it assumed enormous and illegal powers, becoming a court for the trial of all manner of offences which might be construed as ecclesiastical; and was one of the grievances complained of and abolished by the Long Parliament, 16 Ch. I.

High Constable. [CONSTABLE.]

High Pressure. A term applied by Engineers to designate the steam which works engines without being condensed at the end of every stroke; it is usually employed at a high degree of elastic force, the pressure per square inch being about 40 or 60 pounds. In American and in some modern English engines, steam of 120 pounds pressure per inch superficial is used. Condensing engines are not usually called high-pressure engines, though they may employ high-pressure steam.

High Treason. [TREASON.]

Hightate Resin. A fossil resin discovered on cutting the road through Hightate Hill: it is embedded in the London Clay in detached nodules.

Highness. A title first attributed to bishops, afterwards to European kings in general (succeeded by *majesty* in the sixteenth century), afterwards to sovereign princes and their descendants. The title of *royal highness* was first assumed by the duke of Orleans, brother of Louis XIII., in 1631; and it is now conferred on all royal princes and princesses, whether in the direct line of succession or not. The elector of Hesse Cassel and the grand dukes of Germany have also the title of *royal highness*. The children of the emperors of Russia and Austria, and their descendants, are styled *imperial highness*; and all other princes not included in the above category bear the title *serene highness*, being an equivalent for the term *Durchlaucht*, by which they are addressed in Germany.

Highway. In English Law, a highway is a way over which the public at large have a right of passage, and includes a horse road, or a mere footpath, as well as a carriage road. Any way common to all people, without distinction, is a highway. A public-navigable river is also called a highway. The right of the public in a highway is, however, a right of passage over it and nothing more. The soil itself, and all the profits upon it or underneath it, as mines, minerals, &c., and also any strips of waste land lying between the highway and the lands adjoining it on either side, belong to the owners of adjoining lands. But if such strips of waste land be contiguous to or communicative with an open common, they are then taken to be part of the common. A highway may originate from a continual user of land by the public in traversing it without interruption from the owner, or from an express dedication of it by him to their use. A much shorter period of user will establish a right in the public than a right in any private person to a way; the user in the former case being so open and notorious that the owner of the land may fairly be presumed to have had early notice of it, and to have assented to it by not opposing it. Accordingly, a public way may be acquired by an enjoyment for five or six years, although twenty years' enjoyment is necessary in the case of a private way. A highway may also take its origin from statute, or from necessity. A highway originates from necessity when the accustomed line of highway is out of repairs so as to be impassable; in which case the public have a right to traverse the adjoining ground.

The duty of keeping highways in repair is cast by the common law upon the occupiers of lands in the parish generally; but particular persons may be liable to repair by prescription or tenure. They may also be liable in respect of enclosure; that is, if a highway be free from fences on either side, and the owner of the adjoining land chooses to fence it off from the highway, he will then be liable in respect of his enclosure, because he has thereby deprived the public of using his land as a way of necessity, in the event of the original highway becoming impassable for want of repair. The omission

HILUM

to repair on the part of the parish or party liable is an indictable offence, and may be punished accordingly. Various statutes regulated the mode in which the occupiers in a parish were to contribute labour, carts, and cattle, for the purpose of repairing highways, and to perform upon them what was therefore called statute duty; but these purposes are at the present time provided for by a highway rate. Highways are frequently placed by the legislature under the jurisdiction of trustees; such highways are popularly called *turnpike roads*. If sufficient materials for the repair of roads cannot be found on the waste lands of a parish, the surveyors have authority to take them from the lands of any private person (with certain exceptions).

The laws for the regulation of highways were consolidated and amended by the 5 & 6 Wm. IV. c. 50, further amended by 4 & 5 Vict. cc. 51 & 59, and 8 & 9 Vict. c. 71. Formerly, as appears above, if land had been traversed as a way by the public for a few years without interruption, a highway was at once established, and the liability to repair it was cast upon the parish; but by the law as now established no road is to be deemed a highway which the inhabitants of a parish shall be compellable to repair, unless the inhabitants of the parish, in vestry assembled, shall deem it of sufficient utility to them to justify its being kept in repair at the expense of the parish. If the vestry shall not deem it of such utility, the party proposing to dedicate the new highway may be summoned to appear before the justices at special sessions, when the question is to be determined. By stat. 25 & 26 Vict. c. 61, the justices of any county are empowered to form it, or any part of it, into a *highway district*, to be governed by a *highway board*, with the object of securing increased efficiency, by adopting unity of management of the highways.

Hilum (Lat.). In Botany, the scar on a seed which shows the point where it was attached to the placenta.

Himalayan Chain. This loftiest mountain chain of the earth is the southernmost of several considerable ranges forming the great mountain axis of the Old World. It is generally regarded as consisting of three parts, the Hindu Coosh or Indian Caucasus to the west, the Himalayas strictly so called, and the mountains of Assam, the three together forming a continuous group. The valley of Cashmere separates the two first-named divisions, and the valley of Bhotan the two latter.

The principal mountains of the chain are cut by narrow ravines, and rise from very elevated plains to heights varying from 20,000 to 28,000 feet, with very few practicable passes, and these at great elevations.

The Indus and the Ganges rise within this chain of mountains, and are fed by numerous tributaries proceeding from the higher valleys. Although the snow-line is at an extraordinary height, the principal peaks and highest parts of the valleys are all within it, and the glaciers are few but very extensive. The snow-line is

HIPPOBOSCA

much higher on the north than on the south side, notwithstanding the difference of latitude and the less favourable exposure; but this, no doubt, arises from the clearer state of the air and the radiation of heat from the neighbouring high plains.

Many secondary chains are connected with the main chain of the Himalayas; some of them are extremely lofty and grand, and some are metalliferous.

Cultivation is carried on to a great elevation in the plains and on the mountain sides of this chain. Corn is cultivated at 16,000 feet in Chinese Tartary, and even in some places at 18,500 feet. Tall birch-trees occur at 14,000 feet, and in many parts the climate is much more mild than at far lower elevations under the equator in South America. There are no volcanoes in the Himalays, but hot springs rise in many parts to the surface.

Himantopus (Gr. *ἡμάντιος*, from *huds*, a *thong*, and *πος*, a *foot*). This name is now restricted to a genus of *Grallæ*, or wading-birds, in which the legs are proportionally longer and more attenuated than in any other species: the bill is long and slender, depressed at the base, and compressed toward the tip, with the nasal groove extending half the length of the bill. This genus includes the British species called the common stilt, or longshanks (*Himantopus melanopterus*). It is an occasional visitor, and a rare bird.

Himyaric Inscriptions. Inscriptions found in Arabia, exhibiting the primitive type of the oldest form of the language still spoken in South Arabia. These inscriptions have been investigated since 1830 by Gesenius, Rödiger, Fresnel, and Ewald.

Hip. The fruit of the Dog Rose (*Rosa canina*). It furnishes the *conserve of hips* of Pharmacy, which is a convenient vehicle as a pill-basis, and for electuaries and linctuses.

Hipparion (Gr. *ἵππιδιον*, *pony*). A fossil genus of *Equidæ*, from the miocene deposits of Eppelsheim and the Sewalik hills in India. These deposits have yielded molar teeth differing from those of existing horses chiefly in the distinctness or greater extent of separation of the interlobal or inner column; and hoofs in which the second and fourth digits (suppressed under the form of splint bones in the existing horse) were retained as in typical *Perissodactyla*, in a functional state.

Hippides. The name under which Latreille and Eichwald designate a family of the tribe of Macrourous Decapod Crustaceans, typified by the genus *Hippa*.

Hippobosca (Gr. from *ἵππος*, a *horse*, and *βόσκει*, I *feed*). A genus of Dipterous insects belonging to the Viviparous section of the order, in which the young are not only excluded from the ovum, but undergo their first metamorphosis in the womb of the parent, and are brought forth in the pupa state. (*Pupipara*, Latr.; *Homaloptera*, Leach.) The genus is now the type of a numerous family (*Hippoboscidae*), generally known by the name

HIPPOCAMPUS MAJOR

of forest flies and divided by recent entomologists into numerous subgenera. The horsefly (*Hippobosca equina*) is the type of the family.

Hippocampus Major. A long curved eminence on the floor of the middle or descending cornu of the lateral ventricle of the brain. It follows the direction of the cornu towards its anterior extremity, and is notched, or indented, on its surface. [Brain.]

Hippocampus Minor. This structure has also been termed *pes hippocampi minor*; *unguis*; *eminentia unciniforme*; *ergot de Morand*; *calcar avis*; *eminentia minor digitata*; *ocrea*; and *colliculus*. It is situated on the floor of the posterior horn of the lateral ventricle, on which it forms 'a longitudinal eminence corresponding to a deep sulcus between two convolutions.' (Gray, *Anatomy*.) No such structure, corresponding in position and shape to the anthropotomist's definition, has yet been discovered in any known ape. (Cruveilhier, Tiedemann, Owen.)

Hippocastanum. The Horse-chestnut. [ÆSCULACEÆ.]

Hippocras. Spiced wine. The following is one of the most approved recipes for its preparation: 2 ounces of cinnamon, half an ounce of cannella a'ua, and of cloves, mace, nutmeg, ginger, cardamoms, each 1 drachm: these are to be finely bruised and digested for three or four days, in a warm place, in a mixture of 12 quarts of canary and Lisbon wines: the liquor is then to be filtered, and 3 pounds of refined sugar added.

Hippocrateaceæ (Hippocratea, one of the genera). A small natural order of plants of the Rhamnal alliance, distinguished from *Celastraceæ* by little except the flowers being triandrous, and the filaments broad at the base. There are few species of general interest included in the order. Some species of *Tontelea*, however, produce sweet edible fruit.

Hippocrates' Sleeve (Lat. *Manica Hippocratis*). An old pharmaceutical term signifying a conical bag or strainer made of flannel or linen, in the shape of a jelly-bag.

Hippocrene (Gr. *ἵπποκρήνη*, a horse fountain). A fountain at the foot of Mount Helicon, supposed to have been produced when the horse Pegasus struck his foot against the mountain. It was regarded with peculiar veneration, as it was believed to be a favourite haunt of the Muses, and was looked upon as one of the chief sources whence the poets drew their inspiration. [MUSES; PEGASUS.]

Hippodrome (Gr. *ἵπποδρόμος*). In Ancient Architecture, a place appropriated by the Greeks to equestrian exercises. The most celebrated hippodromes of antiquity were those of Olympia and Constantinople; the former was four leagues long and one in breadth. The term is still used, to express the arena devoted to spectacles in which horses are made to appear.

Hippogryph. A fabulous animal, represented as a winged horse with the head of a griffin.

HIPPURIC ACID

Hippomanes (Gr. *ἵππομανές*, from *ἵππος*, a horse, and *μανία*, madness). The Manchineel belongs to this genus of *Euphorbiaceæ*. It is a tree called *H. Manchineella*, and grows forty or fifty feet high in the West Indian islands, &c. The milky juice is extremely virulent, causing blindness if the least drop, or even the smoke of the burning wood, comes in contact with the eye. Salt water is said to be an efficacious remedy.

Hippopotamus (Gr. *ἵπποπόταμος*, the river-horse). A genus of aquatic Pachyderms, represented at the present time by two species (*Hippopotamus amphibius*, Linn., and *Liberienseis*, Morton), which inhabit the rivers of Africa. The generic characters are four toes on all the feet, inclosed in small hoofs; six molar teeth on each side of both jaws; very large and strong canines, of which the upper ones are nearly straight, the lower ones curved, and working upon each other so as to produce a chisel-edge; four incisors in each jaw, the upper ones short and conical, and bent inwards towards the mouth; the under ones long, cylindrical, and pointing forwards. The hippopotamus lives during the daytime immersed in the waters of its native rivers, rising to the surface and protruding its nostrils for the purpose of breathing: it comes to the land to feed during the night. Remains of species of hippopotamus are found in the tertiary formations of Europe; one of these species hardly exceeding the size of a hog. In the tertiary beds at the base of the Himalaya range, an extinct species of hippopotamus has been discovered which had six incisor teeth in each jaw (*Hexaprotodon*, Falconer).

Hippopus (Gr. *ἵππος*, and *πούς*, a foot). The name of a genus of Acephalous Molluscs, significative of the resemblance which their shell bears to the foot of a horse. The valves of this shell are equal, regular, but inequilateral and transverse; the hinge has two compressed unequal teeth; the ligament is marginal and external. The *Hippopi* belong to the family *Tridacnida* of the Lamarckian system; but are distinguished from the genus *Tridacna* by having the posterior slope and lunule closed, or nearly so, and the inner margin dentated at that part. The spines which arm the ribs are tubular, and are never arched or vaulted. The type of the genus is the *Hippopus maculatus*, or spotted hippopus; the *Æstrea hippopus* of Linnæus.

Hippuric Acid (Gr. *ἵππος*, and *οὐρός*, urine). This acid is contained in the urine of herbivorous mammifera, and in small quantity in human urine, in which it may be produced by the use of benzoic acid, which in passing through the system is converted into hippuric acid. It may be obtained by adding milk of lime to fresh cow's urine, boiling, filtering, neutralising the filtrate with hydrochloric acid, and evaporating it to about one-eighth of its bulk; excess of hydrochloric acid is then added, which throws down impure hippuric acid. It may be purified by dissolving it in boiling alcohol, which on

HIPPURIS

esolving deposits it in colourless four-sided prisms with pointed terminations. It requires about 600 parts of cold water for its solution; it is abundantly soluble in boiling water and in alcohol, but less so in ether. The composition of this acid is represented by the formula $C_{12}H_8O_2N + HO$.

Hippuris (Gr. *ἵππουρος*, a horse-tail). The botanical name of the Common Mare's-tail, a native aquatic plant of the dicotyledonous class, chiefly remarkable for its external resemblance to the cryptogamic Horetails (*Equisetum*).

Hippurite Limestone. An important representative of the cretaceous rocks in the South of France and the Pyrenees, characterised by the large admixture of shells of the family *Rudiste* among the fossils. The same character is found to prevail in the cretaceous rocks of Greece and the Mediterranean shores. Many genera of *Rudiste* are found, but the *Hippurites* are the most striking.

Hippurites. A genus of extinct bivalve Molluscs, referred to the extensive group called *Rudistes* by Lamarck. The principal valve of the present genus is of a sub-cylindrical or elongated conical form, traversed by one or more internal longitudinal ridges, and closed by a small sub-circular discoid valve like an operculum.

Hippus (Gr. *ἵππος*). A spasmodic affection of the iris, occasioning repeated dilatations and contractions of the pupil of the eye.

Hips. In Architecture, the inclined diagonal edges of a roof where the sides intersect; hence a hipped roof is one in which two sides at least must intersect.

Hircin (Lat. *hircus*, a he-goat). A term applied by Chevreul to a liquid fatty matter which may be separated from mutton suet, and gives it a peculiar rank smell, resembling that of a male goat. When saponified, it produces *hircic acid*.

Hiring and Service. In Law, the general rule with respect to hiring and service is, that if there be no special agreement, but a general one without mention of time, the hiring is for a year certain; if the servant continue in his employment beyond that year, a second year is implied, &c. Consequently, if a master dismiss a servant hired generally, the servant is entitled to wages for the current year, unless the dismissal be for such a cause as will legally absolve the master from his contract: e. g. moral misconduct or refusal to obey orders. But in the case of domestic servants the contract is, by general custom, dissoluble by a month's warning on either part, or payment of a month's wages.

Hirsute (Lat. *hirsutus*, bristly). In Botany and Zoology, when an animal or plant is covered with long stiffish hairs.

Hirudines. [LÆCH.]

Hirundo (Lat. a swallow). A genus which forms the type of the Fissirostral or wide-gaping Passerine birds of the Cuvierian system. It is now divided into the subgenera *Cypselus*, in-

HISTORICAL CREDIBILITY

cluding the swift and *Hirundo* proper, the chimney swallow (*Hirundo rustica*), sand martin (*Hirundo riparia*), &c. Our British species are occasional visitors, and the heralds, generally speaking, of the summer season, though we see now and then a premature straggler, which has given rise to the proverb, 'One swallow does not make a summer.' Africa appears to be the chief resort of the British species during the winter season. Their disappearance at this season has, it is true, been accounted for on the hypothesis that the swallows passed the winter in a torpid state, submerged in river-heads or other fresh waters. No warm-blooded and quick-breathing animal does or can hibernate under water; and with respect to a bird, it is sufficient to remark that its extra-vascular plumage would be destroyed and decomposed by a six months' immersion. Swallows, like the cuckoo, immigrate to us for the purpose of breeding.

Hisingerite. A hydrated silicate of peroxide of iron, found in Sweden and Germany; occurring in rounded nodules. Named after Hisinger the mineralogist.

Hispid (Lat. *hispidus*, rough). In Botany, a term used in describing the superficial appendages of bodies, to denote their being covered with long rigid hairs, as the stem of *Echium vulgare*.

HISPID. In Zoology, when a surface is rough from minute spines, or very rigid bristles.

Hister. A Linnæan genus of Coleopterous insects, now raised to a family (*Histeride*), belonging to the section *Pentamera*, and the subsection *Clavicornes* of Latreille. Many of the species of this family are remarkable for the instructive promptitude and perfection with which they alter their ordinary appearance when alarmed, by drawing in their antennæ and folding up their legs, so as to feign death, and in many cases to assume the appearance of a small black pebble or seed; whence one of the species is called *Seminulum*. It is this habit which probably suggested the generic name, from the Latin *histrion*, an actor. There are about fifty known British species referable to the Linnæan genus, and now divided into the subgenera *Abræus*, *Orithophilus*, *Dendrophilus*, *Platysoma*, and *Hister* proper.

Histology (Gr. *ἱστός*, a tissue, and *λόγος*). The doctrine of the animal tissues.

Historical Credibility, Law of. The tests for measuring the trustworthiness of any narrative of alleged facts must form the basis of historical science, as distinguished from what is commonly called the philosophy of history. The latter strives to interpret historical phenomena in accordance with psychological or other theories: the former seeks only to determine the truth of facts as they are determined in judicial processes. It is obvious that the importance of this task cannot possibly be exaggerated; and it may also be said with truth that the nature of the work has been clearly recognised only within the present century. A writer like Gibbon, dealing with a

HISTORICAL CREDIBILITY

period for the whole of which we may be said to have narratives of contemporary historians, may not feel the want of the criticism which must be applied to the history of periods not known to us in the same way. But the earlier portions of the history of every nation fade away, by the admission of all, into tales which are indefinite and uncertain, or into legends which are manifestly self-contradictory; and it is clear that the tests applied to measure the value of these portions must, if correct, give us the law of historical credibility—a law of universal applicability and admitting of no exception. It seems also clear that the method adopted by even the most accurate writers down to a very recent time could not make us acquainted with any such law. The Homeric tale of the Trojan war is full of miracles and marvels: the heroes who are prominent in it are the offspring of divine and human parents; while the gods mingle visibly in the strife, and wound others or themselves are wounded and bleed. This exquisite tale of Helen and Achilles, which reappears in germ in Vedic hymns, and is presented to us in more sombre garb in Norse and Scandinavian epics, has been rationalised by Thucydides, the most severely accurate of contemporary historians, into a narrative as trustworthy to all appearance as that of Hallam's *Constitutional History of England*. This result is attained by casting away every portion of the narrative except that which seems to point to national movements or furnish the clue of some political motive; but if the materials cannot be trusted, the rationalised narrative is, of course, as great a fiction as the poetical tale which it is designed to supplant. The early chronicles of England start with the tale of the same Trojan war, and give a long dynasty of British princes in whose veins flowed the blood of Anchises and Priam. The supernatural or marvellous element in these traditions was as distasteful to Milton as to Thucydides; but the rejection of this element left him satisfied with the *caput mortuum* which then remained. 'Those old and inborn kings,' he tells us, 'never any to have been real persons, or done in their lives at least some part of what so long hath been remembered, cannot be thought without too strict incredibility.' So far as keeps aloof from impossible or absurd, I refuse not as the due and proper subject of story.' When, however, Niebuhr reconstructed the ancient history of Rome, it was thought that the revolution in historical criticism had at length been accomplished. With vast learning and a marvellous memory, Niebuhr undertook to disentangle the twisted skein from which he felt sure that he could extract a narrative as thoroughly trustworthy as the life of Charlemagne by Eginhard. Knowing that oral tradition is not to be depended on for more than a few generations at most, knowing also the tendency to exaggeration or falsehood which must prevail where there is no written literature to check it, and that an artificial chronology brings the whole narrative for which it has been

framed into extreme suspicion, Niebuhr began his work in a spirit of unbounded confidence, and grounded his own claim to authority not only on his acquaintance with really historical documents, but on a certain insight, almost amounting to an instinctive or divining faculty, acquired by one who has devoted himself wholly to the subject. The result was that, while he exhibited the transparently artificial character of the chronology, while he acknowledged the anachronisms and other contradictions with which the story abounded, he yet insisted that he had discovered the political history of the regal period, and established the certainty of revolutions which he himself had got at only by inference from traditions and from the manifest incompatibility of the constitution of Servius Tullius with the facts or alleged facts of the later narrative. Nothing could exceed the ingenuity with which this work of reconstruction was effected; but unless the actual evidence of fact could be urged for every single step, the whole process was simply empirical. The extreme impolicy and danger of such a method as Niebuhr's has been pointed out by Sir G. Cornewall Lewis, who, in his invaluable work on the *Credibility of Early Roman History*, has examined the several classes of historical materials, and swept away the plausible fallacies which exaggerate or impair their value. Under his rigid scrutiny, the uncertainty of conclusions based on public monuments, chronology, lists of officers or kings, family chronicles, poems and lays, has been laid bare with a force and a system not attained by any previous writer. The conclusion is perfectly simple. The testimony of contemporary witnesses is the indispensable condition of all genuine history; and the extent of the reliance placed on them must be determined by the same tests which are applied to the testimony of witnesses in a court of law; but in general it is presumed that a man speaking of what he has seen or heard immediately from eye-witnesses is speaking the truth, unless there be some apparent motive for falsehood, or some bias, whether from political feeling or religious enthusiasm, which lessens or destroys his title to credit. We cannot, however, enter here into an examination of the tests which are applied to discriminate between what is true and untrue in the statements of men, as they relate matters falling within or transcending the standard of ordinary experience. The question is one of the highest importance, as on the answer to be given to it depends our belief in the possibility or impossibility of sorcery, witchcraft, and other topics relating to the action of the spiritual and invisible on the visible and material world, which at no very distant day were the subjects of a legislation as inhuman as it was minute and definite. [WITCHCRAFT.] But a few remarks on the various kinds of historical materials will suffice to show how completely we must fall back for the ascertainment of all facts on the one canon by which judicial examinations are guided at the present day.

HISTORIOGRAPHER

back, to use the words of Sir G. C. Lewis, on 'the tests by which the reality of modern facts is determined,' and these tests can be satisfied with nothing less than the word of contemporary witnesses whose credibility must be sifted by the rules already stated. The reader who may wish to examine the subject further is referred to Grote's *History of Greece*, part i.; Sir G. C. Lewis, *Credibility of Early Roman History*, and *Astronomy of the Ancients*; Cox, *Persian War*, part ii.; *Edinburgh Review*, July 1862, p. 97, &c.

Historiographer (Gr. *ιστοριογράφος*). A professed historian, or writer of histories. It has been a common, although not uniform, practice in European courts to confer the place of public historiographer on some learned man as a mark of royal favour. Voltaire had at one period the title of Royal Historiographer of France.

History (Gr. *ιστορία*, from the verb *ιστορέω*, *I enquire*). This word is first used in the commencement of the work of Herodotus, which he there calls by the title *Historia*. It is probable that this writer thus fixed the sense in which the word has ever since been used—as applicable, strictly and properly, to the civil history of man, although it has been analogically used to express other branches of investigation, as in the term Natural History, still in use.

Civil history, properly so called, has also been subdivided into several branches: first, according to the class of events or actions which is made the subject of narration; as ecclesiastical, political, and literary: secondly, according to the extent of the subject; as universal history, in contradistinction to the history of particular nations or districts, or to that of individual men, more properly termed *biography*.

In a general view of civil history (if we remember always that such divisions are after all arbitrary), the whole subject may perhaps be conveniently classed under five heads:—

1. The Jewish history, as contained in the Old Testament.

2. The history of the empires and states of antiquity in that portion of the world known to the classical and Jewish historians, and illustrated by classical and Jewish history; viz. Assyria, Persia, Egypt, Phœnicia, and its colony Carthage.

3. Classical history, properly so called; the history of the national affairs and conquests of the Greeks and Romans.

4. The history of those nations and states (chiefly Oriental) which possess annals of their own, independent of classical, Jewish, and modern European literature; China, India, modern Persia, Arabia, and the Mohammedan conquests.

5. Modern European history, including that of the colonies and conquests of Europeans.

1. The Jewish history, as we have said, is to be found in the Old Testament, some Apocryphal books, and in the writings of Jewish

HISTORY

authors, as Josephus and Philo, who have investigated the antiquities of their country.

2. Of Assyria, Egypt, Phœnicia, ancient Persia, Carthage, &c., we possess no historical notice except such as is derived, 1. From Jewish or classical authors; 2. From monuments, especially in Egypt. Phœnician historical authors (Sanchoniatho, Berosus, &c.) are referred to by classical writers, and perhaps their works have been in part abridged by them; but we have no actual remains of their compositions on the authenticity of which reliance can be placed. With respect to Persia, much industry has been expended in endeavouring to extract from the histories of modern native writers coincidences with the narrations of Greek and Roman authors; and the recent discoveries of Layard, Rawlinson and others are thought to have thrown much light on this branch of our subject, though their full value is not as yet determined.

3. The poems of Homer are generally regarded as containing the oldest fragments of Grecian history; but from these we can infer little more than the existence of certain towns, or the prevalence of certain customs, at the time in which the poems were composed. An examination of the Trojan legend with the mythology of other portions of the Aryan race, has shown that there is no real ground for theories which connect the war of Troy with the movements of Hellenic colonists in Western Asia, or with any other political causes. [Epic.] Herodotus is the oldest Greek prose writer. His invaluable history comprises a description of several countries bordering on Greece and the Mediterranean; concise narratives of Egyptian, Persian, and Assyrian history; and a connected account, more or less detailed, according to circumstances, of the history of Greece, both civil and domestic, for about fifty years previous to the invasion of Xerxes, with which his annals close (B.C. about 480). The history of the Grecian commonwealth is pursued in detail by Thucydides and Xenophon for about a century afterwards. After that period our knowledge of Greek domestic history is confined to the incidental notices derived from contemporary writers, and the general compilations of later historians, varying greatly in trustworthiness and authority. [HISTORICAL CREDIBILITY.] Among these may be mentioned, as authors from whom a large portion of our actual knowledge is derived, Diodorus Siculus, the author of a very miscellaneous general history, of which great part is lost, who live about the age of Augustus; Polybius, whose history is more especially devoted to Roman affairs; Arrian and Quintus Curtius, the historians of the conquests of Alexander; Livy, as to the transactions between Greece and Rome; Justin, the compiler of a brief but useful abridgement of general history; Plutarch, in his *Lives of Illustrious Men*, &c. These writers bring the student down to the period of the subjugation of Greece by Rome; after which all history, of

HISTORY

Greek affairs, properly so called, terminates, until the establishment of what is known as the Eastern empire, and we have little knowledge of the state of Greece and the Græco-Asiatic kingdoms in their provincial state.

Ancient Roman history, down to the first Punic War, is chiefly known from the compilations of Livy and Dionysius of Halicarnassus, writers whose credit is rendered extremely doubtful by modern investigation; and, where these fail, from incidental sources. In the History of the Punic Wars, the narrative of Livy is aided by the admirable work of Polybius. From the end of the second Punic War to the dictatorship of Sulla (nearly 150 years), our materials for Roman history are very deficient; the want of contemporary writers being supplied only by later compilations, and by the incidental knowledge derived from writers on various subjects, the course of whose composition led them to touch on past events—of whom the most valuable is Cicero. From the period of Sulla's dictatorship to the accession of Vespasian (nearly 150 years), we have the advantage of a succession of contemporary writers, some of them actors in the events which they describe, and comprising some of the greatest names in literature—Sallust, Cicero, Cæsar, Velleius Paterculus, Tacitus. Yet even here there is one considerable *lacuna*, comprising the last thirty years of the reign of Augustus, as to which our knowledge is scanty. From the accession of Vespasian to the reign of Constantine, a long period elapses, during which our historical acquaintance with the events of an empire then comprising the greater part of the civilised world is vague and defective. Dion Cassius and Herodian are the two best writers on history who can be named in this long interval; the latter, during the short epoch which he illustrates as a contemporary, is full and valuable. After the accession of Constantine, we have abundant materials for history, both ecclesiastical and civil, from the hand of contemporary authors, down to the reign of Justinian in the East and of Theodoric in the West, although the quality of the writers is sensibly degenerated. Perhaps the comparative obscurity and uncertainty into which history is plunged after the last of these two epochs, and the absence of all standard writers after Procopius, render it the best period to fix upon for the arbitrary limit between ancient and modern history. It will be seen from this brief summary that the only periods of any extent as to which we have the assistance of contemporary historians (or original authority, properly so called), in the whole extent of classical history, are—

1. As to Greece, from B.C. 500 to B.C. 380;
2. As to Rome, from the dictatorship of Sulla to the accession of Vespasian (B.C. 76 to A.D. 70); and, finally, the reigns of Constantine and his successors.

4. After the downfall of the Roman empire, a long series of revolutions in dynasties and nations followed before Western Europe was

parcelled out into the several great countries which, notwithstanding all subsequent changes in political limits, have since subsisted as geographical divisions—Britain, France, Spain, Germany, Italy, the Scandinavian regions. Another period elapsed before the three great countries of Eastern Europe—Russia, Poland, Hungary—were added as distinct members to the family of European states.

From the abdication or deposition of Augustulus and the so-called fall of the Roman empire to the revival of literature (a period comprising in round numbers about eleven centuries), our knowledge of the affairs of Western Europe is derived from a series of writers, in each country, who are usually comprehended under the title of *chroniclers*. A chronicle, or book of annals, is properly a history of which the continuous narrative is so interrupted that each year forms a separate section, and events are thus related nearly in strict chronological order. This is a form very commonly adopted by the historians of the dark ages, of whom the greater proportion were monks. But a great many of the histories of the middle ages are not even in the form of chronicles; they have all the requisites which the most fastidious criticism can require of a regular history.

The Venerable Bede, who wrote in the ninth century, presents us with the first name of true credit and authority among the annalists of England. Of our monkish Latin chroniclers in later times, Matthew Paris is perhaps best entitled to the character of an historian. After the period of the invaluable Saxon chronicle, we have no vernacular English histories worthy of note, with the exception of a few *meagre* rhyming chronicles, until the revival of letters and discovery of printing. In France, the long collection of native Latin chroniclers presents us with few names of interest after the time of the celebrated Gregory of Tours; but the Crusades called forth, for a short space, an unusual spirit of historical description. When we arrive, however, at the fourteenth and fifteenth centuries, we find among the native French historians two authors, of great value as intimately acquainted with the events of their own times, Froissart and Philip de Comines. The annals of Italy are to be sought in the pages of a long series of chroniclers, from the eighth century downwards, of whom the most valuable are published together in Muratori's great collection. Their works are uniformly in Latin until the thirteenth century. But towards the end of that age the Tuscan dialect was elevated, as it were at a single step, to the rank of a literary language; and the little Tuscan republics produced a succession of historians, many of them remarkable for the purity of their style, and some (as the three Villani of Florence) for their extensive information and historical talent. Germany and Spain, in the middle ages, produced few historical works above the rank of dry chronicles. But the annals of the Scandinavian nations form the

most important part of their early and peculiar literature. The Greek empire produced, also, a series of chroniclers, whose works have been collected in the *Corpus Historia Byzantine*.

The period known as that of the revival of letters, and the following century, were distinguished by the appearance of several writers of first-rate merit in the department of history. In Italy, Guicciardini; in France, De Thou; in Spain, Herrera; and our own Camden may be added, not without justice, to the number. To follow the progress of history in modern times would be an impossible task. Suffice it to say, that with the advance of literary knowledge and the increase of education, historical writers seem to become more strongly divided into two very different classes: those who furnish contributions towards the history of their own times, especially the writers of memoirs—of which France gave the first examples, and still produces the most numerous; and the historians, more properly so called, who collect, discuss, and criticise, endeavouring to extricate the truth from the mass of former materials. The latter, in our times, has become more peculiarly the province of literary men. Philosophical history, in which the mere narrative of facts is regarded as subordinate to the elucidation of general truths, and too frequently to the establishment of favourite theories, is a modern improvement in the art; and Voltaire is commonly regarded, not without some truth, as the founder of the school of philosophical historians, among whom the highest rank in popularity has been attained and deserved by Gibbon. But it may be said, with truth, that the present century has carried the science of philosophical and of political history very far beyond those which preceded it. The names of Sismondi, Miguel, Thiers, H. Martin, Thierry, Michelet, Hallam, Macaulay, Niebuhr, Schlosser, Ranke, Finlay, Grote, Milman, Cornwall Lewis, and many more, might be cited in proof of this assertion.

5. The history of the more remote Oriental nations, and also of those which derive their religion and civilisation from Arabia, may be conveniently classed apart, as being derived from wholly different sources. Chinese and Indian history form two entirely distinct bodies of knowledge. With regard to that of the Mohammedan nations, it may be observed that it is brought into contact with that of modern Europe in several distinct countries and periods; of which the most remarkable instances are the Crusades, the annals of the Moors in Spain, and the history of the Turkish empire in its transactions first with the Greeks, and afterwards with the other nations of Christendom.

Histrionic Art. The art of acting in dramatic representations is not unfrequently so called, from the Lat. *histrion*, or *hister*, an actor. [THEATRE.] The word *histrion* is of Etruscan derivation, as was the Roman dramatic art also. (*Mém. de l'Acad. des Inscrip.* vol. xxvii.)

Hitch. In Naval affairs, a particular kind of knot, of which there are several, and all of

which have more or less the character of nooses. [KNOT.]

Hithe. An old English word, signifying a port, wharf, or minor harbour, at which goods are shipped or landed; Queenhithe on the Thames is an example.

Hitopadesa. In Sanscrit Literature, a *Friendly Instructor* or collection of fables, commonly known as the fables of Bidpai or Pilpay. This collection has circulated chiefly in India; but another portion, under the title *Calila* and *Dimna*, is famous through Western Asia and in Europe.

Hives, Bee (A.-Sax. hyfe). The ingenuity of man has devised a great variety of bee hives, which may be conveniently classified as follows: 1. Those which do not admit of enlargement; as the common straw hive or *skep*. 2. Those capable of being added to from above; as the ordinary cottage depriving or capped hives. 3. Those capable of being added to from below; as *nadir* hives. 4. Those capable of enlargement both above and below; as storied hives. 5. Those capable of being increased sideways; as the collateral hives. 6. Those in which each comb is contained in a separate removable frame; as the leaf hive of Huber, or the more recent frame hives. 7. Those intended to afford facilities for observation; as the unicom and other observatory hives. 8. Those in which the bees are not circumscribed for space; as the American box hives.

As the management of bees in these several hives varies considerably, it will be desirable to speak of each somewhat in detail.

1. *The straw skep*, or hive generally employed in this country, is a familiar example of the first class, viz. those not admitting of enlargement. The method of management generally pursued is very simple. The swarms of one year are allowed to remain for two seasons, or till the autumn of the second year, when the bees are destroyed by the fumes of burning sulphur, and the contents of the hive appropriated. The chief recommendations of this plan are its extreme simplicity and the facility with which it can be carried into operation by unskilled persons. The drawbacks to it are, that it necessitates the destruction of the bees (often of much greater value than the honey obtained), and that it yields only a small amount of inferior honey, mixed with bee-bread, and contained in old dark-coloured brood-comb.

By a slight variation in the mode of management, much better results may be obtained on this system. The young hives of the current season should be destroyed, instead of those which are older. The reasons for this choice are several. As the first swarm is always led off by the old queen, the colony founded by it is usually less prolific than that from which it proceeded, and which is governed by a young queen of the current year.

The comb contained in the young hives is much whiter and more free from bee-bread than that in the old hives; consequently, the honey yielded by it is far purer in quality. The old

HIVES, BEE

hives which are kept for the issue of swarms will answer this purpose for a great number of years in succession.

In this country the single hives are usually constructed of straw. Straw has the advantage of not transmitting the heat of the sun very readily to the interior; but, when hives are properly shaded, it offers no advantages over wood, which is in many other respects far superior.

2. The most simple improvement in bee management consists in the addition of a cap, small hive, or super to the stock hive. For this purpose the latter should have a flat top, which should be perforated with an opening or openings capable of being closed when access to the super is not required. *Depriving hives* may be constructed of straw or wood; but metal slides or lids to close the openings should not be employed, as, from the great conducting power of metal, it becomes cold in winter, and in that condition condenses the moisture of the hive, which, trickling down the combs, renders them mouldy and unhealthy to the bees.

The management of depriving hives is very simple. When the stock becomes numerous and the secretion of honey by the flowers is abundant, the openings in the stock hive are uncovered, and the cap or super which is to be filled with honeycomb is placed over the hive. If the time has been well selected, and especially if the bees are attracted by fixing some pieces of clean empty comb in the super hive, it is generally at once occupied and filled with pure white honeycomb, free from bee-bread or brood, and worth from four to five times the value of ordinary run honey, obtained on the single hive system. Many persons employ bee-glasses instead of straw or wood supers, but the bees do not take readily to glass, even when darkened; and its employment, therefore, is not desirable.

3. *Nadir hives* are those in which room for the storage of surplus honey is added below the stock hive. The circumstance that the bees always convey the honey to that part of the hive farthest removed from the entrance, renders this arrangement one of the least profitable in actual practice; and, consequently, nadir hives are not to be recommended.

4. *Storied hives*, as their name implies, consist of several stories, which can be placed one over the other; they may be either circular, square, hexagonal, or octagonal. The stock hive, or principal portion, should not contain less than 1,600 cubic inches of space. The mode of management is sufficiently simple. When the hive becomes populous in the spring or early summer, the top box is placed over the hive, and communication made between it and the lower box. An additional box is added below the stock box, to prevent the issue of a swarm, which, by the removal of a very large number of working bees, would greatly lessen the honey-gathering powers of the colony. If a swarm of great size, weighing not less than

four or five pounds, and consisting of 20,000 to 24,000 bees, is placed in a storied hive, the top box may even be put on, during the first season, as soon as the stock hive is filled with comb. A well-stored super may thus be obtained. This proceeding, however, is not practicable with ordinary sized swarms of three pounds weight, unless two of them are joined together. There is no system of bee-keeping that yields such profitable results as this. Top boxes of pure white virgin honey, weighing from twenty to thirty pounds each, are constantly produced in good seasons, and meet with a ready sale at four times the price of ordinary run honey.

In Ayrshire, where profitable bee-keeping is better understood than in any other county in Great Britain, the storied hives are almost exclusively employed; and from the skill with which they are worked, aided by the meteorological advantages of the district, yield the largest and best honey harvests known in the kingdom. The boxes employed in Ayrshire are octagonal, about fifteen inches in diameter by six in depth. They communicate with one another by long apertures, which may be closed with slides. Four of these boxes constitute a hive. Of these, two form the stock box for the winter. The super or top box, and the lower box, are only added during the honey-gathering season.

5. *Collateral Hives*, in which increased room is given at the sides, were invented many years since by the Rev. Stephen White, and were advocated during the present century by Mr. Nutt. The impossibility of preventing the queen from passing into the side boxes and depositing eggs, which are always accompanied by bee-bread, renders the plan far inferior to the system last described, and it is rapidly passing out of favour amongst the best practical bee-keepers.

6. *Frame Hives*. Hives in which the bees are compelled to build each comb in a separate frame have been long known. The *leaf hive* of the justly celebrated Huber consisted of rectangular frames placed side by side, and closed in at the extreme ends; these formed a perfect hive when in contact; at the same time every single leaf with its contained comb was capable of being readily removed for observation or deprivation of honey. Since the time of Huber, hives in which the frames are made to lift out from the top have been designed by various apiarians in Germany, England, and America; and in the hands of skilled bee-masters they have proved most advantageous, as they place every comb under perfect control, and admit of the performance of many operations, such as rearing of additional queens, the artificial production of swarms, the deprivation of early honey, &c.

The increased expense of *frame hives* over simple storied hives is, however, one drawback to their general adoption; and the greater skill required in their management, and the less marketable form in which the surplus stores are

HIVES, BEE

removed, render them less suited for ordinary bee-keepers than the storied boxes.

7. *Observatory Hives.* Hives intended to afford unusual facilities for observing the actions of the bees are formed of glass. One of these, known as the *unicomb hive*, is so narrow as to admit of the construction of only a single comb; consequently the cells on both sides are visible, and the deposit of eggs by the queen and the rearing of the young are constantly open to observation. Unicomb hives are useless for practical honey-collecting purposes, as they afford no space for extra stores; and, from their construction, the bees necessarily perish during the winter. A permanent observatory hive, in which the bees are open to observation at all seasons, has been designed by Mr. Tegetmeier. It is formed by constructing each side of the hive of four parallel plates of thin glass, placed very close to each other, so as to include three intervening layers of air. As thus constructed, the hive retains its temperature so perfectly, that the bees remain protected from cold even in winter, and they can always be seen.

8. *American Box Hives.* The well-known circumstance that bees often collect enormous stores of honey when building their combs in a large space (as under the roof of a house) has led to the design of hives of immense size. Some employed in America have been as large as sentry-boxes. These large boxes are easily stocked by supporting a hive of bees on a few cross-bars placed in the interior, when the bees rapidly extend the combs below the small hive, often completely filling the box. The plan is not so advantageous as might at first appear, as all the combs contain brood and bee bread, and the honey yielded is consequently always impure, and moreover, is not easily obtained without destroying the bees.

The plans followed in preserving honey for use vary considerably.

Top boxes or supers of pure virgin honey should be allowed to remain untouched until required for use, as, if kept in a cool place, the honey will remain in the cells in a liquid condition for many months, retaining also its delicate aroma, which it loses on being drained from the comb.

When it is required to run the honey from new white comb, a very good plan is to cut it up and stand the vessel in which it is placed in boiling water, when the comb melts and rises to the top, and may be removed when cold, leaving the honey in a pure state below. Honey thus heated retains its liquid character for a much longer time than when drained from the comb in the ordinary manner.

With old comb containing bee-bread this plan is inapplicable; and the comb should be cut up, and the honey drained out through a sieve. It is impossible, however, to obtain honey from old comb uncontaminated by some portion of bee-bread, and by the colour of the old brood cells; and, consequently, its flavour and appearance are inferior to those of virgin honey, stored in new comb.

HOARD

Wax is always regarded by bee-keepers as a product of secondary importance; the quantity contained in the largest hives rarely amounting to more than two pounds in weight. Wax is most conveniently obtained from the old combs by heating them in boiling water, pressing the melted wax through a pointed canvas bag, and allowing it to flow into cold water; it is then collected, and re-melted with a gentle heat.

Bleached or white wax is formed by exposing yellow wax in thin flakes to the action of the sun and air.

Hoard (A.-Sax. *heordan*). In communities where property is insecure, and government rapacious or capricious, it is a very natural act to secrete such personal or movable property as can be conveniently collected in small compass, and is ordinarily secure from depreciation. The precious metals, and to some extent precious stones, are commodities of this character. They represent great value in small compass, and the precious metals at least are of universal and permanent acceptance. The practice of private hoarding is fundamentally due to a desire for security; and even when governments are just and honest, habits often only traditional, or consequent upon past experience, or even resulting from a morbid secretiveness, will lead individuals to hoarding. To some extent hoarding is compensative to discovery; and as the practice is limited ordinarily to the precious metals, it often forms a regular process by which part of that which the miner collects in order to add to the currency of civilised communities, is steadily restored to the earth from which it was originally taken. In all likelihood the fact that India has been for many centuries the recipient of vast quantities of silver from the western world, but has not till lately experienced any notable rise in prices, is due quite as much to habits of hoarding, as it is to the practice of employing a large amount of silver for purposes of personal ornament. In the middle ages, too, when government meant spoliation, and any evidence of wealth was a perpetual pretext for extortion, persons often buried treasure; and by their neglecting to supply a key to its locality, the treasure, as far as society was concerned, was lost. So constant was the habit, that *treasure trove*, i. e. specie buried and abandoned, was a notable source of crown income, the right to which was generally reserved even in the largest and widest grants. For different but analogous reasons, the buccaneers of the seventeenth century were said to have buried a large portion of their spoils on the coasts and islands of the American continent; and it is often asserted, that during the times of terror in France, and even throughout the era of the Revolution, the émigrés had made similar deposits, and that, either from their dying or by becoming the victims of the Convention before they had communicated their secret to survivors, all trace of the hoard has been lost.

Even, however, where there exists no neces-

sity for hoarding, due to the obvious impulse towards self-preservation, ignorance or habit may lead to the practice. Monarchs used to hoard in order to meet political exigencies. States have hoarded in order to create reserves on which to operate. Individuals have hoarded, either because they were ignorant of the machinery by which their accumulations might become profitable, or from some mad passion of miserly secretiveness.

Among Political Economists, the word *hoard* is used in a special sense. It is applied partly to accumulations of wealth not actually employed for a profit and in the hands of the public; partly, but less accurately, to the reserves of banks. Such accumulations are of great monetary significance. In the first place, they form a fund from which in particular emergencies a supply can be afforded for foreign investment, extraordinary payments, or even for commercial transactions. High rates of interest, joined with sufficient or apparently sufficient security for advances, will often extract these hoards in large quantity for some occasions. It cannot be doubted that on and after the suspension of cash payments, the high rates of profit consequent on some occupations during the Continental war, liberated these accumulations, and kept up in some degree the supply of the precious metals. This utilisation of hoards has been frequently effected on different occasions in France, where the practice of specie accumulation is common. And in the next place, the reserves of banks fulfil, as securities against contingencies, the same purpose of self-preservation which suggests private hoarding.

Money and such substitutes of it as are actually circulated alone affect prices. Hence no hoard will either raise or depress money values. Again, the price of money is determined by all the values which it represents, and is, therefore, relative to all the transactions which are based upon it. But a hoard is not, by its terms, circulating; and therefore, while it may act as a reserve, it can have no influence on money values. As the practice of private hoarding is gradually dying out in England owing to the general facilities for banking, the amount of hoards is being more and more concentrated in the shape of bankers' reserves.

Hoary (A.-Sax. *har*). In Botany, a term used in describing the superficial appendages of bodies, denoting their being covered with very short dense hairs, placed so closely as to give an appearance of whiteness to the surface from which they grow.

Hobby (a word of doubtful origin). The name of the small nimble horse on which the light cavalry of the middle ages in England were mounted. [HOBIERS.]

Hobblers or **Hoblers** (Low Lat. *hobellarii*). In England, feudal tenants bound to serve as light horsemen or bowmen; for the word seems to have been of somewhat uncertain employment. The smaller feudal gentry were long styled in France *hebrcaux*.

Hook Day, Kake Day (Ger. *hoch, high*). A festival formerly observed in England on the second Tuesday after Easter, in commemoration of the destruction of the Danes in the time of Ethelred.

Hocus-pecus. A term given to conjurors' tricks, and said to be a corruption from the Latin words *Hoc est corpus* in the office of the Mass.

Hodograph (Gr. *hōs, a path*, and *γράφω, I trace*). A curve imagined by Sir W. R. Hamilton (*Proc. of Roy. Irish Acad.* vol. iii.) to illustrate the theory of central forces. It is thus described: Upon the perpendiculars let fall from the centre of force upon the several tangents to the orbit set off, from that centre, distances proportional to the velocities with which the body moves at the points of contact of those tangents. When the law of attraction is that of the inverse square of the distance, the orbit is a conic of which the centre of force is the focus; and by a well-known theorem the locus of the feet of perpendiculars let fall upon tangents, in other words the *pedal* of the orbit, is a circle. On the other hand, it follows from the law of equal description of areas [CENTRAL FORCES] that the product of each perpendicular into the corresponding velocity is constant, so that the hodograph is the inverse of the pedal, and therefore the reciprocal of the orbit. [PEDAL CURVES.] But the pedal being a circle, its inverse must also be a circle [INVERSE CURVES]; so that all orbits of the solar system have *circular hodographs*. Sir W. R. Hamilton, in the memoir above cited, establishes many interesting properties of the hodograph.

Hoe (Dutch, *houwer*). In Agriculture and Gardening, an instrument for stirring the surface of the soil, cutting weeds up by the roots, and earthing up plants. The hand hoe is a thin plate of iron six or eight inches broad, and sharpened on the edge, fixed at right angles on the extremity of a pole or rod, which serves as a handle. This is called a *draw hoe*, because in the operation of hoeing the instrument is drawn or pulled towards the operator. Another kind of garden hoe has the blade or iron plate fixed on the extremity of the handle, and in continuation of it: and this is called a *thrust hoe*, because in hoeing the operator always pushes the hoe forward. This kind is also called a *Dutch hoe*, most probably from having been first introduced from Holland. In agriculture, hoes of the thrust kind are drawn by beasts of labour, and commonly called *horse hoes*. In general form they resemble a plough; but in stead of the share they have one or more iron blades, or plates with sharp edges, fixed to perpendicular iron rods at their lower extremities. These sharpened plates being drawn through the soil, cut through the roots of weeds an inch or two beneath the surface. Agricultural or field hoes are only used in the case of those field crops which are sown or planted in rows. There are a great many kinds of field

HOEING

or horse hoes, chiefly differing in the number of blades which are attached to the common frame for stirring and cleaning a greater or smaller number of spaces between the rows of drilled crops at once.

Hoeing. The operation of stirring the surface, cutting off weeds, or earthing up plants with a hoe. In the case of any of these operations dry weather must be chosen, otherwise the result will either be useless or injurious. Plants rooted up by the hoe in wet weather will produce fresh roots and grow again, while plants earthed up under similar circumstances will have the leaves which are covered by the soil decayed by it. In either case also the ground will be hardened by the treading of the feet of men or horses, so as to obstruct the progress of the roots, and to exclude air and water from penetrating through it to them. Hoeing is sometimes performed on surfaces which are without weeds, for the purpose of stirring the soil; but in such cases pronged hoes, or hoes having three or more long spikes or teeth, are more effective than hoes with broad plates or blades.

Hog. In Naval affairs, a brush with a stout long handle, used for scouring barnacles and weed off a ship's bottom.

Hog. In Zoology. [Sua.]

Höganite. A mineralogical synonym of a species of *Natrolite* from Högan, near the lake of Constance.

Hogget. Yearling sheep. A lamb becomes a *hog* in its first winter, and afterwards a *hogget*; and, on losing its coat, a *shearling*.

Hogging. In speaking of a ship, this term has reference to an undue falling of her head and stern, in consequence of weakness in the keel or in the tie provided by the decks. Hogging may be immediately caused by the suspension of the ship on a wave amidst ships, or by her taking the ground.

Hogmanay (said to be from the Norman-French *au gui me nez*, *lead to the mistletoe*). The old name of the last night in the year, among the Scotch, with whom it was a notable festival. (Lockhart's *Life of Scott*, chap. xliii.)

Hogshhead. An ancient measure of capacity, containing sixty-three old wine gallons.

Holst. This name is given to the machinery applied in factories, mines, hotels, &c., for the purpose of raising men, or things, from one level to another; the man-engines are a kind of *hoist*, as are the hydraulic cranes now generally used.

Holcus. One of our wild grasses, of little value in an agricultural point of view, the haze being soft and poor. One of the species, *H. lanatus*, goes by the name of White Fog amongst farmers.

Hold (Sax. *haldan*). The inside of the bottom of the ship. It is divided into compartments by bulkheads across; and contains the ballast, water, coals and wood, provisions and cargo.

HOLD. In Music, the same as PAUSE [which see].

HOLOTHURIANS

Holidays. This term now denotes practically those days, exclusive of Sundays, on which no regular public business is transacted at public offices. They are either fixed or variable, and vary in different public offices. The variable holidays are Ash Wednesday, Good Friday, Easter Monday and Tuesday, Holy Thursday or Ascension Day, Whit Monday and Tuesday. [FRIDAY.]

Holliness. The title by which the Pope is addressed; equivalent to the Latin *sanctitas*.

Hollow Bastion. In Fortification, a bastion in which the terreplein is limited by a line parallel to the scarp, and along which the interior slope of the rampart extends continuously.

Hollow Revetments. [REVELMENTS.]

Hollow Shot. Empty shells, with metal screw plugs, sometimes used in the navy.

Holly (A.-Sax. *holegn*). The *Ilex Aquifolium* of botanists, of which many beautiful varieties are cultivated as ornamental shrubs. The Holly is one of the most useful of evergreens for garden decoration.

Hollyhock. A popular flower of the late summer season, whose tapering flower spikes, well placed in a garden, have a very fine appearance. The garden Hollyhocks are varieties of *Althea rosea*, and one or two closely related species, as *chimensis* and *seifolia*.

Holm (A.-Sax.). An island, or fenny place surrounded by water. Two well-known islands in the Bristol Channel are called the Steep Holm and Flat Holm.

Holm Oak or Holly Oak. [QUERCUS.]

Holmste. A mineral identical with Clintonite, named after Holmes, who analysed it.

Holocaust (Gr. *δόκαω*, *to burn*, from *δολος*, *whole*, and *καίω*, *I burn*). A solemn sacrifice among the ancients, in which the whole of the victim was consumed upon the altar, in contradistinction to the usual custom of burning only a portion. A similar custom prevailed among the Jews; it is called in the books of the Old Testament a *whole burnt offering*.

Holocephali (Gr. *δολος*, and *κεφαλή*, *head*). An order of fishes, distinguished by the following characters: jaws bony, traversed and encased by dental plates; endoskeleton cartilaginous; exoskeleton as placoid granules; most of the fins with a strong spine for the first ray; ventrals abdominal gills laminated, attached by their margins; a single external gill aperture. Only two genera (*Culiorhynchus* and *Cestracion*) are known to exist at the present day. The fossil species range from the bottom of the oolitic series of rocks to the present period.

Holograph (Gr. *δολος*, and *γράφω*, *I write*). In the Civil Law, a will written entirely by the hand of the testator.

Holothurians (Gr. *δολοθόριον*). The name of the family of Echinoderms, having the genus *Holothuria* for its type. The body presents a subcylindrical elongated form; is defended by a coriaceous not spiny integument, open at both ends, and perforated by numerous small canals, in linear series, through which prehensile and

HOLT

adhesive suckers are protruded. At the anterior extremity is the mouth, surrounded with complicated retractile tentacula. At the opposite end is the aperture of the cloaca, in which the rectum and a respiratory branched tube terminate. The intestine is very long, and convoluted; and it frequently happens that when the animal is disturbed, it is protruded from the body or ruptured by the violence of the contraction of the muscular parietes of the abdomen. The *trepang* of Eastern commerce is a dried species of *Holothuria*.

Holt (A.-Sax. *a wood*; Ger. *holz*). The termination of many names of places in England, derived from their ancient situation in a wood.

Holy Alliance, The. A league foisted between certain of the principal sovereigns of Europe, after the defeat of Napoleon at Waterloo: on the proposal, it is said, of the Russian emperor Alexander. It arose from the religious enthusiasm which was prevalent at that period of deliverance from French domination, and with which the czar was just then considerably imbued. The act of this alliance is said to have been sent in his handwriting to the emperor of Austria and the king of Prussia, and signed by them. It is not supposed that the original terms of the league were other than indefinite; for the maintenance of justice, religion, &c. in the name of the Gospel. But it was subsequently connected with the determination of those monarchs to support, in conjunction with England and France, existing governments throughout Europe, by the Declaration of November 1819. Afterwards the congresses of Troppau, Laybach, and Verona established the character of the alliance, to which the war of France against Spain, in 1823, gave additional illustration. But England may be said to have finally abandoned its principles in 1827, France in 1830.

Holy Rood or Holy Cross. A festival kept on September 14, to commemorate the exaltation of the Holy Cross. It is from this circumstance that the royal palace in Edinburgh has derived its appellation.

Holy Stone. A soft stone used for scouring the decks of ships.

Holy Thursday or Ascension Day. In the Roman Calendar, the 39th day after Easter Sunday. A festival in commemoration of Christ's ascension.

Holy Week. The last week in Lent, called also in England *Passion week*, as the period of our Lord's sufferings and death.

Homage (Lat. *homagium* or *hominium*, from *homo*, *man*, the usual term by which the vassal or dependant of a prince is designated in the older writers of the middle ages). The symbolical acknowledgment of dependence due from a vassal to a feudal lord or superior when invested with a fief, or obtaining it by succession. In the earliest periods of the feudal system, fealty and homage appear to be confounded (Sir F. Palgrave *On the English Commonwealth*, vol. ii. p. cccxc.); but in later times the distinction was clearly established,

HOMICIDE

and fealty might sometimes be due where homage was not. Homage was either *homagium ligeum*, *lige* *homage*, by which full and unreserved allegiance was rendered; or *homagium non ligeum*, *simple homage*, a mere acknowledgment of feudal superiority, with a saving or exception of the rights of other feudal lords. The one was personal, and could not be renounced (hence the doctrine of *alligance*); the other bound the vassal only so long as he held the fief in respect of which it was due.

Homaliaceæ (Homalium, one of the genera). A natural order of arborecent or shrubby epigynous Exogens, inhabiting the tropics. According to Brown they are related to *Passifloraceæ*, but distinguished by their inferior ovary. Lindley places them between *Lauraceæ* and *Cactaceæ*, in the Cactal alliance; De Candolle between *Samydaceæ* and *Chailletaceæ*. They are plants of some beauty, but of no particular use.

Homburg's Phosphorus. Fused chloride of calcium, which is luminous in a dark place after having been exposed to the solar rays.

Homburg's Pyrophorus. [PYROPHORUS.]

Homburg's Sedative Salt. Boracic acid, to which Homburg erroneously assigned sedative powers.

Home. In Naval language, this term is used of anything that is close in its place; it is applied to the sheets of the sails, the shot and cartridge in a gun, and any article of stowage.

Homeric Poems. This title is generally given to the *Iliad* and *Odyssey*, and the hymns which have been preserved to us in honour of Apollo, Dionysus, Hermes and other Hellenic deities and heroes. But the poems which have come down to us are only a small portion of the treasures which were possessed by the Greeks of the age of Pisistratus or Pericles. [CYCLIC POEMS.] The *ILLAD* relates the events of a few months in the Trojan war, which was caused by the theft of Helen by Paris, once called Alexandros: the *ODYSSEY* gives the narrative of the return of Odysseus or Ulysses from Ilion to Ithaca. An examination of these two poems seems to show that the groundwork of the tale is in each case the same, and that this groundwork is common to the epic poems of other nations, as the *Volsunga Saga*, the *Nibelungen Lied*, &c. Hence a presumption arises that these poems were the result of a very gradual growth, and that in them are combined several lays or poems written by several writers. [EPIC.]

Homicide (Lat. *homicidium*, from *homo*, and *cædo*, *I kill*). In Law, the killing of any human creature; which is either justifiable: viz. 1. In case of necessity, public or private; 2. By permission of law for the advancement of justice; 3. For the prevention of forcible and atrocious crime. Or excusable: 1. By misadventure; 2. In self-defence on a sudden affray, or chance-medley. Or felonious: of which the species are: 1. Self-murder; 2. Manslaughter, which is defined 'the unlawful killing of another without malice, express or

HOMILY

implied; 3. Murder, or the wilful killing of another by malice aforethought; 4. Petit treason, which by the Statute of Treasons was confined to the cases of a servant wilfully killing his master, a wife her husband, or an ecclesiastical person his superior; but the distinction in judgment between this offence and murder is now abolished. In the law of France, homicide is of four sorts: assassinat, meurtre (corresponding respectively to our murder and manslaughter), accidental homicide, and homicide committed in self-defence.

Homily (Gr. *δουλία*, an *assemblage*). Used by the early fathers in the same sense as our word *sermon*. Up to the fifth century the practice of preaching was confined to the bishops, and the only homilies extant are of their composition. The term, which has now become obsolete, was in constant use as late as the Reformation; and the English Book of Homilies is a collection of sermons, setting forth the principal doctrines of Christianity, and pointing out the principles of Protestantism; of which the first part was published by Cranmer in the reign of Edward VI., and the second by order of convocation in that of Elizabeth.

Hominy. A kind of meal prepared from maize or Indian corn.

Homo- (Gr. *ὁμός*, one and the same). A prefix used in composition to denote *resemblance*, and thus opposed to *hetero-*, which indicates *difference*.

Homochromous (Gr. *ὁμοχρώμος*, of one colour). In Botany, when all the florets in the same flower-head are of the same colour.

Homœocephalic Representation (Gr. *ὁμοιοκεφαλία*, like; κεφαλή, head). This term is used by Professor J. Aitken Meigs to denote skulls belonging to a particular type of men, which repeat analogically the characters of another type with which they have no direct connection, e. g. between the Awaras and the Peruvians, or between the Bosjesman and the Mongolian races. The occasional development of an *interparietal* bone, formed by the ossified elements of the upper half of the super-occipital, both in the old Aymara skulls on the borders of Lake Titicaca and in many other races of men, forms an example of homœocephalic representation.

Homœomeria (Gr. *ὁμοιομέρεια*, similarity of parts). The name given to the physical theory of Anaxagoras of Clazomenæ, who flourished in the fifth century B. C. According to this hypothesis, every material substance is made up of infinitely small parts similar to itself. This theory bears some resemblance to that of the *monads* of Leibnitz in modern times. [MONAD.]

Homœopathy (Gr. *ὁμοιος*, similar, and *πάθος*, feeling or affection). The homœopathic method of healing diseases was first proposed by Samuel Hahnemann, a German physician, in 1796. It consists in the administration of medicines which are presumed to excite in healthy persons symptoms similar to those of the disease which is to be treated, upon the principle that *similia similibus curantur*. Thus

HOMOGENEOUS FUNCTION

it is maintained that sulphur produces a pustular eruption upon the skin, and therefore cures pustular eruptions; and that quinia produces febrile symptoms, and therefore cures agues, and so forth. Not the least remarkable part of this practice is the smallness of the doses in which the homœopathic remedies are administered, it being presumed that by infinite subdivisions the virtues of remedies are proportionately refined and exalted. A grain, for instance, of any active remedy, such as aloe, is triturated with 1,000 grains of sugar of milk; when this mixture is complete, a grain of it is again diluted with 1,000 of the vehicle; and so of medicines which the ordinary practitioner administers in doses of one or two grains or more, the homœopathist prescribes a millionth or the decillionth of a grain, or even less.

Homœozoic Belts (Gr. *ὁμοιος*, and *ζῷον*, animal). These tracts, defining the boundaries of the geographical provinces of marine animals, are bounded by climatal lines; which are not, however, parallel with lines of latitude, but undulate in subordination to climatal influences of warm or cold oceanic currents, relations of land to water, &c. Of these belts Professor E. Forbes has defined nine; one equatorial, with four to the north and four to the south, which are mutually representative.

Homogamous (Gr. *ὁμόγαμος*). In Grasses, when all the florets of the spikelets of the same individual are hermaphrodite; in Composite plants, when all the florets of a flower-head are hermaphrodite.

Homogeneous (Gr. *ὁμογενής*, of the same kind). Homogeneous bodies are those of which the constituent elements are all similar. Homogeneous quantities are such as can be added to or subtracted from each other.

Homogeneous Function. In Algebra, a function of two or more variables, such that the result of substituting in it tx, ty, tz , &c. . . in place of x, y, z , &c. . . respectively, is equivalent to the multiplication of the original function by a power of t . Thus

$$u_n = F(x, y, z, \&c. \quad .)$$

is called a homogeneous function of the n^{th} degree when

$$F(tx, ty, tz, \&c. \quad .) = t^n F(x, y, z, \&c. \quad .),$$

where n may be positive or negative, integral or fractional. Differentiating the above equation according to t several times successively, and putting, finally, $t = 1$, important theorems, due to Euler, are readily deduced. The two simplest of these are:

$$nu_n = x \frac{du_n}{dx} + y \frac{du_n}{dy} + z \frac{du_n}{dz} + \&c.$$

$$n(n-1)u_n = x^2 \frac{d^2 u_n}{dx^2} + y^2 \frac{d^2 u_n}{dy^2} + z^2 \frac{d^2 u_n}{dz^2} + 2yz \frac{d^2 u_n}{dydz} + 2zx \frac{d^2 u_n}{dzdx} + 2xy \frac{d^2 u_n}{dxdy} + \&c. \quad .$$

whence the general law is evident. In modern

HOMOGENS

algebra, a rational and integral homogeneous function of the n^{th} degree in m variables is called an m -ary n -ic. [QUANTIC.]

The operative symbol

$$\nabla = x \frac{d}{dx} + y \frac{d}{dy} + z \frac{d}{dz} + \&c.$$

has been termed by Carmichael (*Cambridge and Dublin Mathematical Journal*, vol. vi.) the *index symbol* of homogeneous functions. It is obvious, from the above, that

$$\nabla u_n = n u_n, \quad \nabla \nabla u_n = \nabla^2 u_n = n^2 u_n,$$

and generally that

$$f(\nabla) u_n = f(n) u_n.$$

For further consequences of this, see also Boole's *Differential Equations*.

Homogens (Gr. *ὁμογενής*). A name once given to a group of Exogens, which have their wood arranged in the form of a series of wedges instead of concentric circles. This condition is seen in the stems of Peppers, *Aristolochias*, &c.

Homographic. A term of modern geometry, introduced by Chasles (*Géométrie Supérieure*), and applied originally to two geometrical figures so related that to any point in one corresponds but one point in the other, and vice versa; whilst to points, in line, in either figure correspond collinear points in the other. The following special applications of the term are important.

Two rows of points, no matter whether they are in the same line or in distinct lines, are said to be *homographic* when the relation between them is such that each point in the one line determines and is determined by one, and only one, point in the other. (Chasles, *Comptes Rendus*, December 24, 1855.) If m and m_1 be corresponding points of two such series, and i and j_1 two fixed points in the respective lines, then, in virtue of the above definition, the following relation will exist between the distances $i m$ and $j_1 m_1$:

$$A \cdot i m \cdot j_1 m_1 + B \cdot i m + C \cdot j_1 m_1 + D = 0 \quad (1),$$

where A, B, C, D , are numerical constants which will be determined as soon as three pairs of corresponding points have been chosen. If we suppose i and the infinitely distant point in the first row to correspond, respectively, to the point at infinity and to j_1 in the second, then the above equation takes the simpler and very convenient form $i m \cdot j_1 m_1 = k$, where k is a constant still to be disposed of. From this it may readily be shown that two homographic rows of points or *divisions*, as they are sometimes called, *correspond anharmonically*, that is to say the anharmonic ratio of any four points of the one is equal to that of the four corresponding points of the other; symbolically, $(abcd) = (a_1 b_1 c_1 d_1)$. When two homographic divisions are superposed, there are in general two points e and f ; each of which, considered as a point of either series, coincides with its corresponding point; these are called the *common points* of the two rows; they will be real or imaginary according to the nature of the constant k ; in all cases,

HOMOGRAPHIC

however, they are equidistant from the middle point of the segment ij_1 , and in virtue of the anharmonic correspondence of the two series we shall have $(abef) = (a_1 b_1 ef)$ or $(ae_1 ef) = (bb_1 ef) = \&c.$; that is to say, the anharmonic ratio of the common points and any pair of corresponding points has a constant value. Hence, if a single pair of corresponding points are harmonic conjugates with respect to the common points e and f , every other pair will be so; and this will occur whenever the divisions are so superposed that the points i and j_1 coincide, or, which amounts to the same thing, whenever a point m , regarded as a point of either series, corresponds to the same point n , for then $(mnef) = (nme f) = -1$. [HARMONIC ROW OF POINTS.] In this case the corresponding points of the superposed homographic divisions form an *involution* of the second order [INVOLUTION], of which e and f are the *double points* or *foci*, and o , or the middle point of ef (with which i and j_1 now coincide), is said to be the *centre*.

It is evident that any row of points and the row formed by projecting the latter on any other line are homographic, and conversely that two homographic divisions may be so placed as to be projections one of the other. On this account the term *projective*, first proposed by Steiner, is frequently used in place of *homogr.*

The term *homographic*, as applied to two pencils whose elements consist either of right lines, planes, curves, or curved surfaces, has a precisely similar definition; that is to say, two pencils are said to be homographic when the relation between them is such that each element of one pencil determines and is determined by one, and only one, element of the other. It can be readily shown that the elements of homographic pencils correspond anharmonically. To do so in the case of curves, it is only necessary to remember that the anharmonic ratio of any four curves of the pencil is identical with that of the pencil of tangents to these curves at any one of the fundamental points through which they all pass. [PENCIL.]

The term *homographic* is also frequently applied to two geometrical systems whose elements are dissimilar; thus, a pencil of rays and the row of intersections of these rays by a transversal are said to form homographic systems. In this case, however, Chasles would simply say that the systems correspond anharmonically.

The numerous researches of Steiner, Chasles, De Jonquières, Cremona, and other cultivators of modern pure geometry, abundantly prove the importance of the theory of homographic relations. Recent continental mathematical publications, indeed, will be unintelligible unless the reader bring to their perusal a knowledge of the elementary parts of the theory above sketched. Amongst the English works to be consulted on the subject are Salmon's *Conics*, Muleahy's *Principles of Modern Geometry*, and Townsend's *Chapters on Modern Geometry*. On

HOMOLOGATION

the Continent the best works are those of Charles, *Aperçu Historique et Géométrie Supérieure*, &c.; De Jonquières, *Mélanges de Géométrie Pure et Essai sur la Génération des Courbes Géométriques*; Steiner, *Systematische Entwicklung der Abhängigkeit geometrischer Gestalten*; Möbius, *Barycentrische Calcul* (in which the term *collinear* is used in place of *homographic*); and Cremona, *Introduzione ad una Teoria Geometrica delle Curve Piane*, Bologna 1862.

Homologation (Gr. *ὁμολογος*, agreeing with). In Civil Law, the act whereby a competent tribunal recognises and sanctions the acts of private individuals or of an inferior authority. Thus a composition with creditors requires in France homologation by the Tribunal of Commerce.

Homologous (Gr. *ὁμολογος*). A term applied in Euclid to the antecedent, as well as to the consequent, terms in proportionals (book vi. def. 12). Homologous sides in similar figures are those which occupy corresponding positions with respect to the equal angles.

Homologous Series. Groups of chemical compounds, the formulæ of whose members differ from each other by two equivalents of carbon and two of hydrogen, or a multiple of that number. The alcohols, ethers, fatty acids, and organic bases are examples of homologous series.

Homology (Gr. *ὁμολογία*, agreement). In Anatomy, that department of the science which teaches the essential correspondence of parts, either in different animals, or in different segments of the same animal, or in the same segment, and also the correspondence of the parts of an animal with the ideal archetype which has governed the plan of its organisation. Thus, firstly, the wing of a bird is, homologically, the same limb as the arm of a man or the forefoot of a horse; and the *os quadratum* of a bird is shown to be the same bone as the *os tympanicum* of the tortoise, and as the *auditory process of the temporal bone* of a man. They are said to be *homologous* parts, and the propositions are examples of what has been called *special homology*. Secondly, the wing of a bird is the same or correlative part in its segment of the body, as the leg is in a more posterior segment; just as the frontal bone is the correlative element in its segment, with the superoccipital bone in its segment. The wing of the right side is also the answering part of the wing of the left side; in the same way that the right neurapophysis of any given segment answers to the left neurapophysis in the same segment. Propositions of this kind are examples of what is termed *serial homology*; and the parts so corresponding are said to be *homotypal*; thus the arm is the homotype of the leg, the humerus of the femur, the radius of the tibia, the ulna of the fibula, &c. Thirdly, in relation to the archetype of the vertebrate skeleton, the arm is the *diverging appendage* of its segment; the superoccipital bone is the *neural spine*; the exoccipital bone or *condyloid part of the occipital bone* in Anthropotomy is the *neurapophy-*

HOMOPTERANS

sis; the basioccipital bone or *basilar process of the occipital bone* is the *centrum* or *body* of its segment: these propositions are instances of what is termed *general homology*, as being expressive of the highest generalisations in that philosophical department of anatomical science. (Owen *On the Archetype and Homologies of the Vertebrate Skeleton*.)

Homomorphous (Gr. *ὁμος*, and *μορφή*, form). In Botany, applied when bodies of the same order are uniform, or shaped alike.

Homonymous (Gr. *ὁμώνυμος*, of the same name). In Anatomy, this term is synonymous with *homotypal*. 'If those of the right side arise from the left part of the brain, and vice versa, which seems to be the opinion of the best anatomists, then one would imagine that the homonymous nerves of the right and left side must, in crossing over, lie somewhere contiguous to each other, and so impart vibrations to each other.' (Hartley.)

Homonyms (Gr. *ὁμώνυμος*). Words which agree in sound but differ in signification, as the noun *bear* and the verb *bear*. [POLYONYMY.]

Homoousians and Homoioussians. Names by which the Orthodox and Arian parties were distinguished in the great controversy in the fourth century upon the nature of Christ; the former word signifying that the nature of the Father and Son is the *same*, the latter that they are *similar*. [ARIANS.] (Milman's *Hist. of Christianity*, ii. 443.)

Homophonous (Gr. *ὁμόφωνος*, of the same tone). In Music, of the same pitch, or unisonal. Two or more sounds are said to be homophonous when they are of exactly the same pitch.

Homophony. Homophonous words or syllables, in Language, are words or syllables having the same sound, although expressed in writing by various combinations of letters. Languages which abound in homophones are, 1. Some Oriental monosyllabic tongues, namely, the Chinese and its kindred dialects, in which very few sounds comprise the whole vocabulary, and the same sound is expressed by a variety of ideographic characters; in Chinese there are only 400 such sounds, multiplied by the distinctions of tone and accent to 1,600 or 2,000; and, 2. Some European tongues in which, according to the genius of the dialect, the syllables of the original languages from which the words are chiefly derived have been contracted in speaking, and part of their sounds dropped, while the greater part of the letters is retained. Thus in English, and still more in French, which is peculiarly a dialect of Latin abounding in contractions, homophones are numerous; in the latter tongue the number of syllables differently spelt, all having nearly the sound of our broad A, amounts to more than a hundred; while in Italian, in which the original proportions of the Roman language are preserved, they are scarcely to be found.

Homopterans (Gr. *ὁμόπτερος*, of the same plumage). The name of an order of insects, dis-

HOMOTROPAL

membered from the *Hemiptera* of Linnaeus, including those in which the wing-covers are of a uniform semi-membranous consistency. Latreille divides this order into the three following divisions: viz.

1. The *Cicadaries*, having the tarsi three-jointed, and the antennæ very short, terminated by a fine bristle.

2. The *Aphidians*, having the tarsi two-jointed, and the antennæ longer, without a terminal bristle; containing the families *Aphida* and *Psyllids*.

3. The *Gallinsecta*, having the tarsi one-jointed, terminated by a single claw. The males have two wings, and are destitute of a mouth; the females are wingless, and furnished with a sucker.

Homotropal (Gr. *ὑπέρω*, *I turn*). In Botany, a term used in describing the direction of bodies, to denote any one having the same direction as the body to which it belongs, but not being straight.

Homotype (Gr. *ὁμός*). In Anatomy, the correlative in one segment with any given part in another segment, or in the same segment, of one and the same animal. Thus the frontal bone is the homotype of the superoccipital bone; the humerus is the homotype of the femur; the parts on the right side are homotypes of those which are repeated on the left side. It is the object of *serial homology* to determine *homotypal parts*. [HOMOLOGY.]

Honey (Ger. *honig*). A sweet liquid secreted by many kinds of flowers, and collected by the honey bee: the portion not required for their food is returned into the combs in the form of a yellow syrup, the qualities of which differ according to the flowers whence it has been derived. In its original liquid state it probably resembles uncrystallisable sugar of fruits, &c.; but when kept for some time, a large portion of it passes into a granular form. Honey also contains a little wax, gum, colouring matter, and mannite. [HYVÆ.]

Honey Dew. A sugary clammy secretion, formerly regarded as being formed by the leaves of plants in hot weather. It appears to be secreted by *Aphides*, and is sometimes so abundant as to fall from the leaves in drops. It is greedily collected by the honey bees, and its recurrence several times during the same season adds greatly to the amount of honey collected by these insects.

Honey Locust. The *Glutischia triacanthos* of botanists.

Honey Stone. A yellow mineral found in octahedral crystals at Artern in Thuringia. It is extremely rare. It consists of a peculiar acid (mellitic acid) combined with alumina and water.

Honeysuckle. The common name of the plants belonging to the genus *Lonicera*, well-known fragrant climbing shrubs, of which two species occur wild in this country. Agriculturists sometimes apply the same name to Meadow Clover, *Trifolium pratense*. The Honeysuckle of Australia is a tree of the

HOOD MOULDING

proteaceous family, the *Banksia serrata* of botanists; and what is called French Honeysuckle is *Hedysarum coronarium*.

Hong. The Chinese name for the foreign factories situated at Canton. The hong merchants alone were legally permitted to trade with foreigners until the treaty with China of 1842. The restriction is now abolished by art. 5 of that treaty.

Honorarium (Lat. from *honor*, *honour*). A term used almost synonymously with *fee*, and applied at present chiefly to the fees tendered to professors in universities, and to medical or other professional gentlemen for their services. It was originally applied solely to the salaries of the great officers of state, whose services it was considered were remunerated only, as it were, *honoris causa*; a shade of meaning which is still perceptible in the present use of the term.

Honour (Lat. *honor*). In Law, this word signifies the more noble sort of seigniories, on which other lordships or manors depend by the performance of customary services.

The term *honour*, in its common sense, is susceptible of various significations; all of which, however, may easily be traced to its original meaning, *esteem or regard built on opinion*. Among the Romans honour was deified; and in modern times the term is used to indicate certain rules by which society in general, and especially that portion of it called *fashionable*, has tacitly consented to regulate its proceedings, any deviation from it being attended by expulsion from its pale. To this class may be referred, with slight modifications of meaning, the phrases *debt of honour*, *law of honour*, *court of honour*, *affair of honour*, &c., which are all self-explanatory. The term was formerly the style of a man of rank generally; but it is now distinctively conferred on the Vice-Chancellors and the Master of the Rolls.

Honour, Legion of. [LEGION, &c.]

Honours. The compliments paid by troops to royalty, officers of rank, &c.; and at military funerals to all grades of the army. A scale of honours is laid down in the queen's regulations.

Honourable. A title prefixed to the Christian names of the younger sons of earls, and to those of all the children, both sons and daughters, of viscounts and barons. It is also conferred on persons filling certain offices of trust and dignity, such as the maids of honour of the queen and queen dowager; and collectively on certain public bodies or institutions, as the House of Commons, the Congress of the United States, &c. &c. The title of *right honourable* is given to all peers and peeresses of the United Kingdom; to the eldest sons and all the daughters of peers above the rank of viscount; to all privy councillors; and to some civic functionaries, as the lord mayors of London and Dublin, the lord provosts of Edinburgh and Glasgow, &c.

Hood Moulding. The moulding which is introduced in Mediæval Architecture, to throw off the rain from the tracery, or to protect it

HOODED SNAKE

from dust, is called the hood moulding. It is generally made of the depth of the arch in which the tracery is introduced; but if the latter be continued below the level of the springing, the hood mould is also prolonged. The character of the mouldings differs slightly in Norman and Pointed architecture; being in the former merely a fillet accompanied by a splay, often ornamented with a billet and zigzag; and in the latter an ogee moulding with a hollow on the side of the tracery. In the English and the perpendicular styles, the hood mouldings are often terminated by brackets, shields, or heads.

Hooded Snake. The Cobra di Capello, or *Naja tripudians* of Cuvier, a poisonous snake frequently used by the Indian jugglers, after the poison-fangs have been removed.

Hookah. An Asiatic pipe, in which the smoke of the tobacco is made to pass through water in order to cool it.

Hooping Cough. A contagious spasmodic cough, of which the medical name is *pertussis*, from the Latin *tussis*, a cough. This disease lasts from three weeks to six months, according to the robustness of the patient, the time of year, or the mildness of the season. It generally attacks children, and commences with simple catarrh, which after ten days or a fortnight assumes the character of hooping cough. The peculiar sound produced by the patient, to which the disease owes its name, is caused by a long and violent inspiration following the numerous expiratory efforts made during the cough. The paroxysms are generally very violent, and terminate in the excretion of a glairy mucous discharge from the bronchial tubes, and vomiting occurs also in most cases. The disease is not accompanied with any febrile disturbance when uncomplicated, and its pathology is still unexplained, belonging as it probably does to the mysterious class of blood diseases. The treatment consists in the exhibition of mild sedatives, sudorifics, and aperients. Rhubarb and ipecacuan are highly extolled, and also prussic acid. Counter-irritation to the spine is practised with occasional advantage. Under all methods of treatment, however, a great point is gained by keeping the patient in a moderate temperature (from 64° to 66° Fahr.), and exhibiting light and nutritious food.

Hoopoe. In Ornithology, the vernacular name of the *Upupa Epops*.

Hop (Ger. *hopfen*, Fr. *houblon*). The *Humulus Lupulus* of Linnaeus, the female flowers of which are used for imparting a bitter flavour to malt liquors for the purpose of preserving them from fermentation. The hop plant is a perennial indigenous to Britain and different parts of Europe; but to produce abundance of hops it requires to be very carefully cultivated in good soil, and even then is one of the most precarious of crops.

The fields in which hops are grown are commonly called hop gardens: a loamy soil on a dry subsoil is chosen, and the plants are placed in hills, stools, or groups of three or

HOP POLES

four, the hills being in rows five or six feet apart, and at about the same distance in the row. A full crop is not produced till the fourth or fifth year after planting. Every year the ground is dug in winter, and kept clear of weeds during summer; and the hills have poles, generally three or four to a hill, for the plants to twine on: the purchase of these poles, the fixing them in the soil every spring, the taking them down and stacking them every autumn, and their renewal every five, six, eight, or ten years, according to the kind of wood used, constitute a considerable part of the expense of hop culture.

The hops when mature are picked by hand, and as they are picked they are carried to a drying kiln [HOP OAST], dried, and packed into bags or pockets; and this is also an expensive process.

The hop plant is particularly liable to be injured by insects, by cold and continued rains, and by thunder storms; in consequence of which it is estimated that a full crop is not obtained oftener than about once in five years. Hence it is easy to conceive that the price of hops must vary greatly in different years, and that the grower who has a command of capital may profit largely by keeping them back from market when the prices are low, and selling them when they are high. In order to keep hops for two or three years, they require to be powerfully compressed, and put into much closer canvas bags than when they are to be sent immediately to market; they also require to be kept in dry airy lofts, neither too warm nor too cold. The culture of hops was introduced into England from Flanders in the reign of Henry VIII. The most extensive plantations are in Kent, Surrey, Sussex, and Herefordshire; but they are cultivated to a considerable extent in other counties. The hop growers are now no longer placed under the surveillance of the excise, the duty having been abolished.

Hop Oast. A particular sort of kiln used for drying hops. The floor of the kiln is generally of wire cloth, and the heat is generated in a stove with flues below. The hops after being put on the kiln are frequently turned, and in general they are rendered sufficiently dry in the course of a few hours; when dried they are taken to a loft and left to cool for a day or two, and then put into bags, having been previously subjected to the slight action of the fumes of burning sulphur (sulphurous acid), by which they are to a certain extent bleached.

Hop Poles. Poles or stakes annually inserted at the roots of hop plants for their stems to twine round. When a hop plantation is first made, as the plants are weak, the poles are not required to be more than five or six feet in length; but in the third or fourth year they require to be ten or twelve feet in length. Any kind of young trees or saplings may be used as hop poles; but the most durable are those of the oak, the ash, the sweet chestnut, and the larch. Much of the durability of the

HOPETTE

hop pole no doubt depends on the soil in which it is grown ; but, all circumstances being alike, poles of larch wood, which are much employed in the neighbourhood of Farnham, have been found to last longer than any other.

Hopette. A mineral named after Dr. Hope, late Prof. of Chemistry at Edinburgh ; it is said to be a hydrous phosphate of zinc and cadmium.

Hoplites (Gr. *ὁπλίται*, from *ὅπλα*, arms). The heavy-armed infantry of Grecian antiquity. According to the Athenian regulations (similar probably to those of other states), the higher classes of citizens only, as estimated by the census, were liable to this expensive form of military service ; in process of time, however, it seems that the Thetes or inferior classes also served as Hoplites. The Hoplites were armed in early times with the spear, heavy defensive armour, and large shield ; the latter were exchanged after the time of Iphicrates for the light cuirass and target.

Horeæ (Lat. ; Gr. *ῥαῖ*). In Mythology, divinities regarded in two points of view—as the goddesses of the seasons, and of the hours of the day. Their duty was to hold the gates of heaven, which they opened to send forth the chariot of the sun in the morning, and receive it again in the evening. No classical poet has described them with greater beauty than Shelley, in his *Prometheus Unbound*. These goddesses are often depicted as forming the train of Aphrodite or Venus. (Homer, *Hymn. ad Ven.* 145 ; Hes. *Erg.* ver. 75, and *Hymn. ad Apoll.* 194 ; Gray's *Ode on the Spring*.)

Horary Circles. On globes, circles marking the hours, drawn through the poles at a distance of 15° from each other. They are the same as *meridians*.

Horary Motion. The apparent motion of a celestial body in an hour. The apparent horary motion of the heavenly bodies in their diurnal revolution is 15° ; for as the whole circle is completed in 24 hours, the twenty-fourth part of it, or 15°, must be passed over in one hour.

Horde. A name given to the migratory bands of nomadic nations who, like the Tartars, unite plunder and rapine with a pastoral life.

Hordein (Lat. *hordeum*, barley). A modification of starch, which constitutes about fifty-five per cent. of barley-meal.

Hordeolum (Lat. dim. of *hordeum*). A small tumour on the eyelid, somewhat resembling a barley-corn ; it is a little boil projecting from the edge of the eyelid, and is commonly called a *stye*.

Hordeum (Lat.). The genus of the Barleys and Barley-grasses, distinguished by having its spikelets in threes, arranged on opposite sides of the rachis, so as to form a distichous spike. [BARLEY.]

Horhound (derivation uncertain). The *Marrubium vulgare*, an indigenous plant with a bitter and somewhat aromatic flavour, and considered as an expectorant, and as giving relief in asthma ; hence the celebrity of *horhound tea* and *candied horhound* among the common people.

HORN-WORK

Horizon (Gr *ὁ ὁρίζων κύκλος*, the boundary circle). In Astronomy and Geography, the plane of a great circle of the sphere, dividing the visible from the invisible hemisphere. The horizon is either *sensible* or *rational*. The sensible horizon is a plane which is a tangent to the earth's surface at the place of the spectator, extended on all sides till it is bounded by the sky ; the rational horizon is a plane parallel to the former, but passing through the centre of the earth. Both the sensible and rational horizon are relative terms, and change with every change of the spectator's position on the surface of the earth ; in all cases they are perpendicular to the direction of gravity.

Horizon, Artificial. The plane of the horizon is a tangent to the curvature of the earth at any place, and is assumed very nearly by the surface of a quiescent liquid, which thus becomes an artificial horizon from which the altitude, of a heavenly body for instance, may be measured. From the law of the reflection of light, it follows that the angle subtended at the eye of an observer by a star and its image as seen reflected from such a liquid surface is twice that of the altitude of the star above the horizon. On account of its high reflecting power, mercury is the liquid generally used for an artificial horizon.

Horizontal Parallax. [PARALLAX.]

Horizontal Range. [GUNNERY.]

Horn. Horny matter in general (such as cow-horn, tortoise-shell, quill, claws, nails, whalebone, &c.), is intermediate in composition between albumen and gelatine ; it does not furnish gelatine when boiled in water, but by the proper application of heat it may to some extent be softened, so as to admit of moulding by pressure into various forms. Horn gradually dissolves in the caustic alkalis, and on neutralising the solution with an acid, a precipitate is obtained resembling that from similar solutions of the albuminoid compounds. The average ultimate composition of horn may be represented as 50 per cent. of carbon, 7 of hydrogen, 23 of oxygen, 17 of nitrogen, and 3 of sulphur. The earthy and saline matters of the more perfect varieties of horn do not exceed 2 or 3 per cent. [CORNUA.]

Horn, French. A brass musical wind instrument of a complex spiral form, increasing in diameter to its end or mouth, which the French call its *pavillon*. The inflexion of it is much regulated by the insertion of the hand in the pavillon. Of late years the scale and intonation of the horn have been very much improved by the addition of valves, as in the CORNET-À-PISTONS [which see].

Horn Silver. A name given by mineralogists and also by the older chemists to chloride of silver, which when fused puts on a horny appearance. For the same reason chloride of mercury or calmel is occasionally called *horn quicksilver*, and chloride of lead *horn lead*.

Horn-work. In Fortification, a work composed of two half-bastions and a curtain, with two long sides called *wings*.

HORNBEAM

The *Carpinus Betulus* of botanists; a useful tree of the Corylaceous order. The wood is white, hard, and heavy (whence the name), but apt to be shaky, and therefore not well adapted for constructive purposes, though it forms excellent fuel. It is also a very useful hedge plant, being patient of the knife, and holding on its dead leaves during the early part of winter.

Hornbills. [BUCCOS.]

Hornblende. A mineral of a dark-green or black colour, abounding in oxide of iron, and entering into the composition of several of the trap rocks. It is the *amphibole* of Haüy.

Hornblende Rock. A rock of which hornblende is the principal ingredient. Hornblende granites are called *eyenite*, and consist of quartz and felspar, with hornblende instead of mica. Hornblende porphyry is quartz and hornblende.

Hornblende Schist. A slaty variety of hornblende, generally including felspar and grains of quartz; it is of a dark-green or black colour. Where clay slate is in contact with granite, it sometimes passes into hornblende slate.

Horner's Method. A method of solving, numerically, algebraic equations of all degrees. It constitutes unquestionably the most important step made in this branch of mathematics since the time of Vieta. It was first published in the *Phil. Trans.* for 1819; its inventor, Mr. W. G. Horner, was at that time a teacher of mathematics at Bath; he died in 1837. We propose here to give a short sketch of the nature of the method, referring readers who may desire to become expert calculators by this method to the *Ladies' Diary* for 1838, to the article 'Involution and Evolution' in the *Penny Cyclo.*, or to Young's or Todhunter's *Theory of Algebraic Equations*, for further details.

The chief merit and peculiarity of Horner's method may be said to consist in a convenient and uniform process for finding the values of the successive derived functions of a given rational and integral function $F(x)$, corresponding to any given value a of x . This process will be sufficiently explained by the following diagram, which has reference to the quintic

$F(x) = Ax^5 + Bx^4 + Cx^3 + Dx^2 + Ex + F$, and in which every new symbol immediately below a horizontal line represents the sum of the two quantities, in the same vertical column, immediately above that line; thus,

$$L = Ka + H, \frac{1}{2}F'(a) = Oa + M, \&c. \dots$$

A	B	C	D	E	F
Aa	Ga	Ha	Ia	Ja	
G	H	I	J	F(a)	
Aa	Ka	La	Ma		
K	L	M	F'(a)		
Aa	Na	Oa			
	O	$\frac{1}{2}F''(a)$			
Aa	Pa				
P	$\frac{1}{6}F'''(a)$				
Aa					
$\frac{1}{2}F''(a)$					

HORNSTONE

$$\text{Now, } F(x+a) = Ax^5 + \frac{1}{1}F'(a)x^4 + \frac{1}{2}F''(a)x^3 + \frac{1}{6}F'''(a)x^2 + \frac{1}{24}F^{(4)}(a)x + F(a),$$

so that by the above process we are enabled to form readily the equation $F(x+a)=0$, whose roots are each less by a than the roots of $F(x)=0$.

To illustrate the application of Horner's method, let us suppose that by STURM'S THEOREM, or in some other way, we have ascertained that $F(x)=0$ has a root between 30 and 40 [THEORY OF EQUATIONS]; then the equation $F(x+30)=0$, which we proceed at once to form, will have a root between 0 and 10. Newton's method of approximation [EQUATION], the last process having supplied the necessary data, will now lead us without much trouble to the determination of two consecutive numbers, say 2 and 3, between which a root of the last equation must lie; so that by repeating the last process we shall be able to form the equation $F(x+32)=0$, whose roots are less by 2 than those of the last: in other words, less by 32 than those of the first, and which further has a root between 0 and 1. Newton's method will now lead to a new approximation, and the operation may be repeated. Proceeding in this manner, it is clear that from $F(x)=0$ we may deduce an equation $F(x+a)=0$ having a root as near to 0 as we please. This done, the corresponding approximate root of the original equation will, of course, be $x=a$. It is scarcely necessary to mention that Horner's method is immediately applicable to the extraction of the ordinary roots of numbers. To find the fifth root of 10, for example, it is merely necessary to solve the equation $x^5-10=0$; in other words, to make in the above scheme

$$A=1, B=C=D=E=0 \text{ and } F=-10.$$

Horner. [VERSIPED.]

Horning, Letters of. In Scottish Law, a species of diligence (i.e. process) against a debtor. They are writs in the king's name, proceeding on the warrant of a decree of the court of session, or of the magistrates of boroughs, and of various other inferior authorities; but in these cases a warrant of the court of session must also be obtained. They direct the debt to be paid within a limited number of days (according to the nature of the debt). In default of such payment the debtor incurs the charge of rebellion, and is thereupon liable to *caption* or arrest.

Hornpipe. The name of a well-known dance, for the skilful performance of which the British sailors have long been celebrated. The origin of the name is uncertain; but it is believed to be derived from a kind of musical instrument called *pib-corn* (Ang. *hornpipe*), consisting of a wooden tube with holes and a reed, and a horn at each end, which was formerly used in Wales. (Barrington's *Archæologia*, vol. iii. 177.)

Hornstone. A variety of flint of a semi-transparency somewhat resembling that of horn. One of the varieties of porphyry goes under the name of hornstone porphyry.

HOROGRAPHY

Horography (Gr. *ῥα, hour*, and *γραφειν, I write*). The art of drawing hour-lines, or of constructing dials.

Horologium Flores (Lat.). A time-table of flowers, formed by noting the hours when they respectively open and close.

Horology (Gr. *ῥα, and λόγος, discourse*). This word signifies literally an explanation of the methods of measuring and marking the hours of the day. Anciently the term *horologium* was applied to any sort of contrivance for measuring the hours, as the *CLEPSYDRA* and *SUN-DIAL* [which see]; but as these instruments have been succeeded by clocks and watches, horology is now usually understood to signify a description of the principles on which machines for the measurement of time, moved by weights or springs, are constructed.

Machines for measuring time are designated by the general appellation of *clocks* and *watches*; but they are also distinguished by peculiar names arising from certain modifications in their construction, or from certain particular purposes which they are intended to serve. By the term *clock* is understood an instrument which not only shows, but also strikes, the hours. A *time-piece* is one which shows the hours without striking them; a *quarter-clock* is one which strikes the quarters as well as the hours; an *astronomical clock* is one which shows sidereal time; a *watch* is a portable or *pocket time-piece*; a *repeater* is one having a contrivance by means of which it can be made at any time to repeat the hours; a *chronometer* is a watch of the best kind, or one fit to be employed for astronomical purposes. A *marine chronometer* is a large kind of watch, specially constructed and hung for sea voyages.

In a general view, horological machines may be regarded as consisting of three essential parts: 1. A moving power, which produces a rotatory motion about an axle; 2. A train of wheel-work, by means of which a velocity is obtained having any required ratio to that of the primary axle; 3. A regulator, by which the rapidity of the revolution is determined, and uniformity of motion produced. The moving power is either a heavy weight which descends by the force of gravity, or a spring which is coiled up within a barrel and unwinds itself by the force of its elasticity: the first is preferred on account of the perfect regularity of its action when the instrument is to remain fixed in a place; the second is necessary for pocket time-pieces and those which cannot be kept in a fixed position, as on shipboard. The train of wheel-work is chiefly remarkable on account of the delicacy and accuracy of its construction. The regulator is either a pendulum, of which, by the theory of falling bodies, the oscillations are isochronal or performed in equal times; or a heavy balance, the reciprocal vibrations of which are also isochronal. [BALANCE; PENDULUM.]

Of the various mechanical contrivances introduced into horological machines for accomplishing particular purposes, it would be useless

HOROLOGY

to attempt a description in this place, as our limits will not permit them to be given with that minuteness of detail which is indispensable in order to convey a clear idea of their action. The most important is the *escapement* (or *scapement*), or that part of the mechanism by which the original rotatory motion is converted into a reciprocating motion, and gives impetus to the pendulum or balance. Some other parts are also of primary importance; as the *maintaining power*, a contrivance by means of which the motion is maintained, or the machine kept going, while the weight or spring is being wound up; the *fusée*, by which in watches and spring-clocks the force acting on the wheel-work is rendered equal in all states of the tension of the spring. [FUSÉE.]

The general arrangement of the wheel-work of a clock or watch may be understood from the following description. Fig. 1 represents

Fig. 1.

the movement of a common vertical watch, the frame plates being omitted, and the dial being supposed to be turned downwards. A is the barrel containing the spring which produces the motion. B is the fusee, connected with the barrel by the chain b. C is the fusee-wheel, called also the *first or great wheel*, which turns with the fusee, and works into the pinion D, called the *centre-wheel pinion*: this pinion, with the *centre wheel or second wheel E*, turns once in an hour. The centre wheel E works into the *third-wheel pinion F*; and on the same arbor is G, the *third wheel*, which drives the fourth or *centre-wheel pinion H*, and along with it the *centre wheel I*. The teeth of this wheel are placed at right angles to its plane, and act in the pinion K, called the *balance-wheel pinion*; L being the *balance-wheel*, or *scape-wheel*, or *crown-wheel*, attached to the same arbor. The balance-wheel acts on the two pallets m and n attached to the verge or arbor of the balance M; and these being placed at a distance from each other equal to the diameter of the balance-wheel, and in different planes, receive alternately from the scape-wheel an impetus in opposite directions which keeps up the vibratory motion of the balance.

This last part of the mechanism, which it requires some attention to understand, is represented more distinctly in fig. 2, where A is the scape-wheel, and B and C the two pallets. The pallets, it is to be observed, are not placed on the verge in the same plane, but their planes form an angle equal to the excursion of the balance; so that, supposing one of them to be about 40° or 50° from the mean point towards the right, the

Fig. 2.

other is just as many degrees from the same point towards the left. The teeth of the scape-wheel are bent forward in the direction of the motion, like the teeth of a saw, and their number is odd. Suppose, now, a tooth of the scape-wheel to have caught the pallet B; it will continue to bear on that pallet, and to accelerate the balance, until, by the revolution of the verge, the extreme edge of the pallet comes into the plane of the extremities of the teeth, when the pallet escapes. But as the balance continues for a short time longer to move in the same direction, the pallet C now comes in between two teeth at the point diametrically opposite to the front of the tooth which B has just quitted; and as the vibration of the balance now commences in the opposite direction, this pallet is in its turn pressed upon and accelerated by the wheel.

The *Crown-wheel Escapement*, now described, is the oldest and the original form, and is still used in common watches, where it answers sufficiently well; but when applied to clocks regulated by pendulums, it is exceedingly defective; for, as it requires the vibration to be made in an arc of considerable extent, the pendulum must of necessity be short and light, and hence it becomes a very imperfect regulator. In order to obviate these defects, Clement, a London watchmaker, in 1680, invented the *crutch* or *anchor* escapement, which was greatly improved upon by Graham about the year 1700. Graham's escapement is represented in fig. 3.

O is the centre of the scape-wheel. B A C, the crutch or anchor, consists of a heavy piece of metal attached to the rod of the pendulum with which it moves. A is its centre of motion; and in the original construction of Graham, the distance of A from O was equal to the diameter of the scape-wheel. The extremities of the crutch form the pallets, the acting faces of which are inclined planes; while the parts on which the teeth successively fall are cylindrical surfaces, the radii of which are equal to O A. The tooth, being received on this surface, slides along it without tending to accelerate or retard the pendulum, until the pendulum arrives near the middle of its vibration, when the inclined plane comes to the extremity of the tooth, and the tooth then begins to act upon the plane, and to turn the pallets, and consequently accelerate the pendulum. By this arrangement the motion of the wheel continues only during the short time the tooth is sliding along the plane of the pallet, while during the rest of the vibration the tooth rests on the cylindrical surface, and the wheel stands still, or is *dead*; whence this escapement is called the *dead beat*, or the *escapement of repose*. In Hooke's form, where the cylindrical surfaces are wanting, the impulse given to one pallet carries the opposite with some force against the approaching tooth, and drives the wheel backward, or produces a recoil; and this force being applied at the extremities of the vibrations, tends greatly to

disturb their isochronism. By Graham's method there is no recoil: the impetus is given while the pendulum is near the middle of the vibration, and the velocity the greatest; and during the rest of the vibration the pendulum is nearly altogether free of the action of the wheels.

Numerous other modifications of the crutch escapement have been proposed, and some of them carried successfully into effect; but for their description we must refer to the works in which the subject is technically treated. There are two, however, which, by reason of the greater ingenuity displayed in their contrivance, and their almost universal application to the best kinds of pocket watches, require particular notice. These are the *duplex* and the *detached* escapement, the latter being that which is used in modern chronometers.

Duplex Escapement.—This is represented in fig. 4. AA is part of the scape-wheel, which is furnished with two sets of teeth, whence probably the name is derived. MNR are the teeth of repose, lying in the plane of the wheel; *mnr* are the teeth of impulse, and stand perpendicular to the plane of the wheel. BC is the impulse pallet, fixed upon the arbor of the balance just above the plane of the wheel, so that its extremity C may be caught by the teeth *mnr*, and receive the impulse from them as they successively pass. A small ruby roller is also placed upon the arbor, behind the pallet, having a notch in one side of it for receiving the teeth MNR. When the tooth *m* has passed the claw of the pallet, the tooth M falls upon the ruby roller, where it rests until by the returning vibration of the balance the notch is brought to the point of the tooth. The tooth then falls into the notch, and thus passes the roller; and the next impulse tooth *n* comes up to the pallet, on the point of which it acts with great advantage in consequence of the long lever. As the successive impulses are all given in the same direction, the balance necessarily makes two vibrations for each impulse given by the upright tooth. The chief advantage of this construction consists in there being only one pallet, and in the action being independent of great accuracy in the execution of the teeth of the scape-wheel, which is indispensable in the case of the escapements already described, and also for the lever escapement, which in fact is only a modification of the crutch.

Detached Escapement.—The annexed diagram, fig. 5, represents Earnshaw's construction. A is the main pallet projecting from the verge or arbor of the balance, concentric with which is another small pallet, called the *lifting pallet*, which, when the balance is vibrating from A towards B, lifts a very slender spring B, and with it the detent spring C, so as to set at liberty or

Fig. 4.

Fig. 5.

HOROLOGY

unlock the tooth D, the point of which rests on a ruby pin projecting from the detent spring C, and forming the detent. The point E of the principal pallet having passed the tooth F, the wheel moves forward by the action of the mainspring, until the next tooth G falls upon the ruby pin and is locked. The screw H serves to adjust the position of the detent and the strength of the locking. In the return of the balance, the pallet A passes easily by the detent spring by forcing back the slender spring B. As in the case of the duplex, the balance here makes two vibrations for each impulse.

Maintaining Power.—In order that a clock or watch, when perfectly regulated, may continue to indicate true mean time, it is necessary that it should have some contrivance for continuing the action while it is wound up. Various methods of accomplishing this have been devised. One of the simplest consists in the interposition of a spring between the fusee and the wheel impelled by it, a little inferior in force to the mainspring (or weight), so as to remain always bent until the pressure of the mainspring is removed by the action of winding, when it begins to act upon a fixed point on one side and the wheel of the fusee on the other, so as to propel the work for a short time with a force nearly equal to that of the mainspring.

Some of the other parts of the mechanism, as the wheels for moving the minute and second hands, the striking part of a clock, and the repeating part of a watch, though they form a considerable part of the bulk of the machine, require no great refinement of invention or dexterity of construction, and will be better understood from the inspection of a common clock and repeating watch than from any description which could be given.

The history of the invention of clocks is very imperfectly known. By some it has been ascribed to Pacificus, archdeacon of Verona, in the ninth century, and by others to Boethius in the early part of the sixth. The Saracens are supposed to have had clocks which were moved by weights as early as the eleventh century; and as the term is applied by Dante to a machine which struck the hours, clocks must have been known in Italy about the end of the thirteenth or beginning of the fourteenth century. It is said that the first clock made in England was furnished out of the proceeds of a fine imposed upon the chief justice of the King's Bench in 1288, and that it remained in its original situation, in Old Palace Yard, as late as the reign of Elizabeth. In the reign of Richard II. a large astronomical clock was made by Richard of Wallingford, abbot of St. Alban's, which was regulated by a fly. But the most ancient clock of which we possess any certain account was erected in a tower of the palace of Charles V., king of France, about the year 1384, by Henry de Wick, or de Vick, a German artist. A clock was erected at Strasburg about 1370, at Courtray about the same period, and at Spire in 1395. In the following century public clocks appear to have

existed in all the principal towns of Europe, and private ones to have come into very general use.

The earliest clocks were doubtless very rude and imperfect instruments, and their present state of excellence must have been attained by slow and successive improvements. Wheel work, set in motion by springs and weights, was known in the time of Archimedes; and in order to have a timepiece it was only necessary to apply some contrivance to regulate the motion. For this purpose recourse was first had to a fly-wheel; but it would soon be found that the fly, the action of which depends on the resistance of the air, would form a very imperfect regulator. The clock of Henry de Wyck, above mentioned, was regulated by an alternating balance, which was formed by suspending two heavy weights from a horizontal bar fixed at right angles to an upright arbor, and the movement was accelerated or retarded by diminishing or increasing the distance of the weights from the arbor. It had no regulating spring, and the action may consequently be supposed to have been very irregular; nevertheless, clocks regulated in this way were used for astronomical purposes by Walther, Tycho Brahe, Mæstlin, the landgrave of Hesse, and others. The capital improvement of the pendulum dates from about the middle of the seventeenth century; but it is very uncertain by whom the application was first made or proposed. Galileo was the first who remarked, or at least the first who formally announced, in his work on mechanics and motion, which was published in 1639, the isochronal property of oscillating bodies suspended by strings of the same length; and it has been pretended that he actually applied a pendulum to a clock for the purpose of observing eclipses and determining longitudes. There is, however, no absolute proof of this fact. Sanctorius, in his *Commentary on Avicenna*, describes an instrument to which he had applied a pendulum in 1612. Richard Harris is said to have constructed, in 1641, a pendulum clock in London for the church of St. Paul, Covent Garden. Vincenzo Galilei, a son of Galileo, is stated, on the authority of the *Academy del Cimento*, to have applied the pendulum in 1649. It was applied by Huygens in 1656; and by Hooke, for whom the invention has been claimed, about 1670. But to whomsoever the merit may belong of having first made the application, Huygens is unquestionably the first who accurately explained the theory of the pendulum; and hence, perhaps, the invention of the pendulum clock has been usually ascribed to him. Huygens demonstrated that the vibrations in circular arcs are not independent of the length of the arc, and that in order to obtain perfect isochronism, the ball of the pendulum must move in the arc of a cycloid; and, ingeniously applying a property of the cycloid, of which he was the discoverer, namely that its involute is a curve similar to itself, he procured the requisite motion by causing the pendulum to vibrate between cy-

HOROPTER

cloidal cheeks about which the upper and flexible part of the suspending rod wrapped itself in its motion. But it was found that no practical advantage could be obtained from this beautiful contrivance; and, in fact, it was soon rendered unnecessary by the invention of the anchor escapement, which gives the means of rendering the arcs of vibration very small, in which case the error depending on the length of the arc becomes insensible. The application of the spiral spring to the balance is the undoubted invention of Hooke.

Another invention, which marks an epoch in the history of horology, is that of a method of counteracting the effect of changes of temperature on the pendulum rod and balance. The mercurial compensation pendulum was invented by Graham about the year 1716. Graham likewise suggested the method of effecting the compensation, by means of the unequal expansions of different metals, an idea which was subsequently realised by Harrison in the construction of the gridiron pendulum, which is now very generally used. The compensating apparatus in the watch balance depends upon the same principle, but the mechanical arrangement is necessarily very different. [BALANCE.]

For full information on this subject, the reader is referred to the following works: Denison, *Rudimentary Treatise on Clocks*; Berthoud, *Essai sur l'Horlogerie*; Id. *Histoire de la Mesure du Temps*; Cumming's *Elements of Clock and Watch Work*; Derham's *Artificial Clockmaker*; Harrison's *Principles of his Timekeeper*; Earnshaw's *Explanations of Timekeepers*; Reid's *Treatise on Clock and Watch Making*; the art. 'Horology' in the *English Cyclopædia*; Beckman's *Hist. of Inventions, &c.*

Horopter. The surface of single vision corresponding to any given binocular parallax is thus named.

Horoscope (Gr. *ὁροσκόπος*, from *ὥρα*, an hour, and *σκοπέω*, I observe). A representation of the aspect of the heavens and positions of the celestial bodies at a particular moment, drawn according to the rules of the imaginary science of astrology. Thus the aspect of the heavens at the moment of the birth of an individual is his *horoscope*, and supposed to indicate his future destinies. [ASTROLOGY.]

Horse. [EQUUS.]

HORSE. In Nautical affairs, a foot-rope to support the feet of the seamen while leaning over a yard or boom to furl the sail. Also, a rod or rope along which the edge or the corner of a sail traverses by means of hanks.

Horse Artillery. [ARTILLERY.]

Horse Fly. [HIPPOBOSCA.]

Horse-chestnut. *Æsculus Hippocastanum*. The seeds of this tree contain a considerable quantity of starch, accompanied by a peculiar bitter principle, tannin, and mucilage. Attempts have been made to separate the starch for domestic purposes, but hitherto without much success. According to Flaudin (*Comptes Rendus* xxvii. 391), when the peeled and bruised chestnuts are well kneaded in a

HOSPITAL GANGRENE

very dilute solution of carbonate of soda, the starch separates, and after having been well washed becomes nearly tasteless. A bitter substance called *argyrosicin* has been extracted from the horse-chestnut by Rochleder. [ÆSCULINÆ.]

Horse-power. The unit adopted in estimating the power of steam engines. It is of the dynamic value of 33,000 lb. raised one foot high per minute. In buying engines a certain area of piston was supposed to represent a horse-power, and in Watt's early engines the dynamic and commercial units were nearly equivalent. This is, however, no longer the case, and in some modern engines the dynamical or indicated horse-power is as much as nine times greater than the nominal or commercial power. [STEAM ENGINE.]

Horseradish. The root of the *Cochlearia Armorata*, which when scraped is often eaten as a condiment and an ingredient in sauces. It has a place in the *Materia Medica* as a stimulant, and a compound spirit and compound infusion are directed in the *Pharmacopœia*: the latter very soon becomes putrid, and neither are useful. The root of *aconite* has occasionally been accidentally substituted for that of the horseradish, and has proved fatal.

Horticulture (Lat. *hortus*, a garden, and *colo*, I cultivate). The culture of the kitchen garden and orchard. In the kitchen garden are cultivated all kinds of root, herb, flower, and fruit, used in cookery; and in the orchard the more hardy fruits used in cookery, and in the dessert. The finer fruits are grown against espaliers, walls, hot walls, or under glass. The chief difference between horticulture and agriculture is, that in the former the culture is performed by manual labour in a comparatively limited space called a garden; while in the latter it is performed jointly by human and animal labour in fields, or in an extensive tract of ground called a farm. [GARDENING; AGRICULTURE; FARMING.]

Hortus Siccus (Lat. a dry garden). A collection of dried plants preserved in books or papers.

Horus or Hor-apollo. In Egyptian Mythology. [HARPOCRATES.]

Hosanna (Heb.). An exclamation, signifying literally *save now*. This Hebrew word occurs only once in the Old Testament, viz. Psalm cxviii. 25. This psalm is the last of those which compose the *great Hallel*. It was commonly adopted in the Christian church.

Hospital (Fr. *hôpital*, from Lat. *hospitium*, a place for lodging strangers). A building for the reception of persons incapable of taking care of themselves, or of procuring medical assistance. Many of the charitable institutions of Great Britain are called *hospitals*, as Christ's Hospital, London, Heriot's Hospital, Edinburgh. The English medical hospitals are incorporated bodies possessed of great wealth, which is expended in the support of medical schools.

Hospital Gangrene. A species of ulcerating gangrene, peculiarly characterised by

HOSPITALLER

its infectious nature, and its tendency to attack wounds or ulcers in crowded and ill-ventilated hospitals.

Hospitaller (Fr.; Lat. *hospitium*). In its original acceptation, this name was applied to certain religious bodies, who held it their duty to provide lodging and entertainment for persons engaged in pilgrimages. One of the most celebrated institutions of this kind was that at Jerusalem, which gave its name and origin to the Knights Hospitallers—instituted about the end of the eleventh or the beginning of the twelfth century. They soon afterwards settled in England, and gradually attained a degree of wealth and importance unequalled in the history of similar bodies. They followed the rule of St. Austin, and wore a black habit with a white cross upon it. At their original institution they were styled Knights of St. John of Jerusalem; afterwards Knights of Rhodes, and again Knights of Malta; these two islands having been successively conferred on them by different monarchs. [ST. JOHN OF JERUSALEM, KNIGHTS OF.]

Hospitium (Lat.). This word signifies in general a place or inn for the reception of strangers, in which sense it is used by old writers; but it is in modern times almost wholly restricted to the celebrated inns on St. Bernard, and St. Gotthard, in Switzerland, to which travellers to and from Italy resort.

Hospodar (Slavonic). The lieutenants appointed by the Porte to govern the two Christian principalities of Moldavia and Wallachia are so called in the Levant. By the treaty of Adrianople between Prussia and Turkey (1829), these officers were to hold their appointments for life, and pay a fixed annual tribute. Under the treaty of Paris, 1856, and by the subsequent arrangement of 1861, acceded to by the Porte, the principalities have been formed into one province, named Roumania, under a single prince.

Host (from the Latin *hostia*, a victim). In Theological language, the bread and wine under the appearance of which the Roman Catholics conceive the body and blood of Christ to be present upon the altar. The elevation of the Host is a ceremony prevalent in all Catholic countries, in which the consecrated elements are raised aloft and carried in procession through a church, or even through the streets of a city. On these occasions the people fall on their knees and worship the Host. The origin of the custom is dated from the twelfth century, when, it is said, it was thought necessary to make this public and conspicuous declaration of the Eucharist on the occasion of the promulgation of the opinions of Berengarius against transubstantiation.

Hostage (perhaps from Lat. *obes*, *obsidis*, through the Low Latin form *obstagius*). A person left as surety for the performance of the articles of a treaty. The practice of taking hostages is now almost unknown in the mutual relations of civilised communities; but was formerly so common as to have given rise to many questions in the law of nations. Hostages were

HOTEL

divided into principal and accessory; the latter being where it is expressly stipulated by treaty that the hostages shall be answerable for the event. One of the points debated among civilians on this subject was, whether such a hostage could lawfully stake his life, and whether in the event of his doing so it was lawful to take it. The affirmative was argued from the most ancient example of hostageship on record, Reuben's words to Jacob, 'Slay my two sons if I bring not Benjamin back.' According to Philip de Comines, the Liegeois having given hostages to Charles duke of Burgundy, with express power to put them to death in the event of an infraction of the treaty, and that event having taken place, it was much debated in the council whether the power should not be carried into execution; but after much discussion their lives were spared. It has also been questioned whether a hostage can be delivered up against his will: Grotius decides in the affirmative. The extent of the rights of conquerors over hostages, the events which may dissolve their obligation, the effect of their escape upon the convention between the principals, and other points of the subject, are treated at length by writers on national law.

Hot Blast. The stream of heated air forced through a furnace is known by the name of the hot blast, when the temperature of the air is made about 300, 400, or even 600 Fahr. The effect of this, in the iron furnace, is the production of a greater quantity of metal from the ore; but the texture of the metal is impaired.

Hot Shot. Common shot heated in a furnace, and fired against shipping and combustible material. When shot are heated, it is necessary to reduce the charge of powder.

Hot Well. The reservoir for the water pumped out of the condenser of a steam engine by the air-pump.

Hotspot. In Law, a blending or mixing together of lands given in marriage with lands in fee falling by descent. As if A had two daughters, and gives a third part of his lands in marriage with one of them to her husband, and dies seized of the other two thirds: in order to acquire any further share of these lands, the married daughter must bring the lands first given into hotspot; that is, she must renounce the gift, and allow the land to be confounded with the rest, in order that she may inherit her whole share; otherwise her sister will have the remaining two thirds of the lands. There is also a rule of hotspot with respect to the distribution of personal property within the stat. 22 & 23 Ch. II. c. 10; as, where a certain sum is to be raised and paid to a daughter for her portion by a marriage settlement, if the daughter would have any further share of her father's personal estate she must bring this money into hotspot, and allow it to form part of the distributable residue.

Hotel (Fr.; Old Eng. *hostel*, from Lat. *hospitium*). This word signifies, in a general sense, a large inn for the reception of strangers; but in France it is applied especially to the residences

of the king, nobility, or other persons of rank: or it is used synonymously with hospital, as the *Hôtel Dieu*, *Hôtel des Invalides*, &c.

Hot-house. A general term for the glass structures used in Gardening, and including stoves, greenhouses, orangeries, and conservatories. Pits and frames are garden structures with glass roofs, with the sides and ends of masonry or wood, but they are generally so low as not to admit of being entered, and this seems to prevent them from being included under the term *hothouse*. [STOVE; GREENHOUSE; PITS AND FRAMES.]

Hotpressing. In Printing, a mode of giving a glossy appearance to books. The printed sheets are placed between glazed or milled boards to a thickness together of about five inches, and laid on two cold iron plates at the bottom of a hydraulic or screw press, then a cold plate, a hot plate, another cold plate, a further supply of sheets between glazed boards, and so on till the press is full. The press is then pumped up, or screwed down with a powerful lever, and left for a short time.

Hottentots. The inhabitants of the southern extremity of Africa. They exhibit many and manifest points of dissimilarity with the pure negroes, with the Caffres, and with the other indigenous African races. They are usually of small size, of a dusky olive complexion; high cheek-bones, and crisp woolly hair. Some of them, as the Griquas, are much mixed with European blood from the Dutch Boers. The Hottentots are on the whole docile, and some have been disciplined as soldiers for the purpose of defence against the other aboriginal tribes.

Hotwall. In Gardening, walls for the growth of fruit-trees, which are built with flues or other contrivances for being heated in severe weather, so as to facilitate the ripening of the wood or the maturation of the fruit. The most common form of hotwalls is that in which flues or tunnels are conducted through them, into which the smoke and heated air from fires are made to ascend from a furnace at the bottom of the wall to a chimney on the top; but in some cases hotwalls are formed by constructing the entire wall hollow, tying the two sides together by cross-stones or bricks, and introducing heat by means of pipes of metal containing steam or hot water along the bottom of the vacuity, the heat of which rises to the top of the wall, and heats every part in its progress. In all climates north of the meridian of London, hotwalls are of great use for ripening fruits and young shoots, and preserving tender plants. [WALL.]

Hound (Ger. hund, Gr. *kúon*). It is not easy to determine from what original stock English hounds have sprung. [CANIS.] The several varieties in this country have during the last century been diminishing in number, and are now reduced practically to three—the foxhound, the harrier, and the beagle. The staghound, now nearly extinct, is a mongrel bloodhound; the latter to produce this variety being

crossed seemingly with some lighter animal, as a greyhound or a lurcher. The foxhound is also sprung from a graft on the old English bloodhound, apparently within the last 150 years. The harrier, now being different from the harriers of half a century back, may be considered as a miniature foxhound. The beagle, an animal with great beauty of form, is now nearly extinct; as a hunting dog, it is comparatively useless, being noisy, and apt to dwell on the scent, while the game is escaping. The greyhound is no longer classified among dogs used in chase, since he has been deprived of the necessary faculty of smell. (Stonehenge, *The Greyhound* in 1864.) The terrier, probably so called from his eagerness to get under ground, no longer accompanies foxhounds, as foxes are not so often digged for as formerly. (*Encyclopædia Britannica*, s.v. 'Hound'.)

Hounds. In Maritime language, the projecting parts of the sides of the mast, near its head, which, like shoulders, support the rigging.

Hour (Lat. *hora*, Gr. *hōra*). In its general acceptation, denotes the twenty-fourth part of a mean solar day, or of the time in which the earth makes a complete revolution in respect of the sun. The division of the artificial day, or time from sunrise to sunset, into twelve equal parts, belongs to the remotest ages of antiquity (Goguet, *Origine des Loix*, &c.); the division of the night into the same number of parts was introduced at Rome in the time of the Punic wars. The Italians make the day commence at sunset, and reckon on to twenty-four hours, or to the succeeding sunset. Astronomers reckon twenty-four hours from midday to midday; but in the civil reckoning only twelve hours are counted, namely from midnight to midday, and from midday to midnight. The hours which result from the division of the artificial day into twelve parts are called *temporary hours*, from being of unequal lengths at the different seasons of the year.

Hour Angle of a Heavenly Body. The angle at the pole between the celestial meridian and the circle of declination passing through the place of the body.

Hour Circles. [Horary Circles.]

Hours. In Mythology. [HORÆ.]

Hours, Canonical. The seven hours of prayer, observed, it is said, by the Catholic church since the fifth century; chiefly in monasteries. The number seems before that time to have varied, although some peculiar seasons of the day and night were always set apart for this observance. They became finally fixed at seven by the rule of St. Benedict; a number, perhaps, recommended by a literal acceptation of the words of David (Psalm cxix.), 'Seven times a day will I praise Thee.' These hours are termed, in the language of the Latin church, *matins*, *prime*, *terce*, *none*, *vespers*, *compline* or *completorium*, which last takes place at midnight. At the time of the Reformation the canonical hours were reduced in the Lutheran church to two, morning and evening; the 'reformed' church never observed them. (Bing-

HOUR-GLASS

ham's *Ant. Ecol.* 5; Ersch and Gruber's *Encycl.* 'Hore.')

Hour-glass. A species of chronometer or clepsydra, measuring intervals of time by the running of water or sand from one glass into another.

Houris. The name given by Europeans to the imaginary beings whose company in the Mohammedan paradise is to form the principal felicity of the *believers*. The name is derived from *hūr al oytūn*, signifying *black-eyed*. They are represented in the Koran as most beautiful virgins, not created of clay, like mortal women, but of pure musk; and endowed with immortal youth, and immunity from all disease. (*Koran*, chap. lv. lvi. Sale's translation; and the *Prel. Discourse*, s. 4.)

House (Ger. *haus*). A human habitation above the ground. Amongst eastern and southern nations, houses are usually found to be flat at the top, with the ascent to the upper storey by steps on the outside. As we proceed towards the north, a declivity of the roof becomes necessary to throw off the rain and snow, which are of greater continuance than in lower latitudes. Among the ancient Greeks and Romans, the houses usually enclosed a quadrangular area or court open to the sky. This part of the house was by the Romans called the *impluvium*, or the *cavadium*, and was provided with channels to carry off the water into the sewers. (*Smith's Dictionary of Greek and Roman Antiquities*, s.v. 'Domus.') The word *house* is used in various ways; as in the phrase *a religious house*, by which either the buildings of a monastery or the community of persons inhabiting them may be designated. In the middle ages, when a family retired to the lodge connected with the mansion, or to their country seat, it was called *keeping their secret house*. (*Northumberland Household Book*. See also *Domestic Architecture in England*: Oxford, Parker.)

House of Commons. [PARLIAMENT.]

House of Correction. A prison for the punishment of idle and disorderly persons, vagrants, trespassers, &c.; regulated by 4 Geo. IV. c. 64 and other statutes. [BRIDEWELL; PRISON.]

House of Lords. [PARLIAMENT.]

Household Brigade. The household troops, consisting of the two regiments of life guards, the royal horse guards, and the three regiments of foot guards, are so called. These troops perform the special duties of honour about the person of the king or queen.

Household Coal. The coals best suited for domestic use are those which burn in a steady and uniform manner, leaving a black cinder and little ash, and giving out the greatest quantity of heat. The district affording this kind of coal in the north of England extends from the Tyne to the Wear, and from the last river to Castle Eden, and occupies another area about Bishop Auckland.

The best household fire-coal was for many years produced from the High Main Coal of the

HOWITZER

Tyne, the immediate colliery being called Wallsend, and hence the origin of the designation Wallsend to distinguish the best household fire-coal. It is also obtained from the various collieries of Percy Main, Walker, Heaton, Willington, &c., on the Tyne, and from the Hutton seam on the Wear.

Household, The Queen's. The chief officers of the queen's household are: 1. The lord steward; in whose office are the treasurer and comptroller of the household, &c. 2. The lord chamberlain, under whom are the vice-chamberlain, lords in waiting, grooms in waiting, gentlemen of the privy chamber, yeomen of the guard, gentlemen pensioners, &c. 3. The master of the horse. The mistress of the robes is at the head of the ladies of the queen's household, and has under her regulation the duties belonging to the bedchamber, and the rotation of service of the several ladies, viz. eight ladies of the bedchamber, eight bedchamber women, eight maids of honour.

Household Troops. [GUARDS.]

Householder. In law, the occupier of a house. Where the right of voting for members of parliament is in inhabitant householders, it has been settled by a current of decisions that no one is to be considered as such who does not possess the exclusive right to the use of the outward door of the building. He retains the character, however, although by taking inmates he may for a time have relinquished the exercise of that exclusive right. The *outward door*, to satisfy this description, need not be a door opening on the public way; a room or set of rooms having a separate and exclusive outward door (as chambers in one of the Inns of Court) may in the eye of law constitute a house. The same principle is followed in criminal law, where to constitute the offence of burglary, it is necessary that a *house* shall have been broken and entered.

Houseleek (A.-Sax. *leac*, a *leak* or *plant*). The *Sempervivum tectorum* of botanists, a plant forming rosette tufts of succulent leaves, from which arise stout flower-stems bearing pink polypetalous star-shaped flowers. It is commonly met with in this country on cottage roofs and old walls, and is esteemed by country people for its cooling properties.

Housing. In Architecture, the space taken out of one solid, to admit of the insertion of another, is called a *housing*.

Howel. An open shed for sheltering cattle, for protecting produce or material of various kinds from the weather, or in which are performed various agricultural operations during heavy rains, falls of snow, or severe frosts. In common language, the term is generally applied to the meanest kind of cottages.

Howen. The inflation of the stomach and intestines of cattle in consequence of the imperfect digestion and fermentation of their food. [TYMPANITIS.]

Howitzer (Ger. *haubitze*, Fr. *obusier*). A piece of ordnance used for throwing shells. Howitzers are shorter, and have much less

weight of metal, than guns of the same calibre. [ORDNANCE.]

Key (Dutch, *huy*). A small vessel having generally one mast, and ordinarily used for the carriage of luggage to and from larger vessels and the shore.

Kubert, Order of Saint. The highest Bavarian order of knighthood, founded in 1444.

Kucho. A species of trout (*Salmo Hucho*) found in the Save, Laybach, and other rivers tributary to the Danube: it attains a weight of about three pounds. 'The skin of this fish is thick; the scales smaller than those of the common trout, and the pectoral fin has four spines more, which I think enables it to turn with more rapidity. Fried or roasted, he is a good fish; his flesh is white, but not devoid of curd, and though rather softer than that of a trout, I have never observed in it that muddiness or peculiar flavour which sometimes occurs in trout even in perfect season.' (Davy's *Salmonia*.)

Kuckaback (Teut. *huycke*, a covering). A coarse table linen or towelling, having the web alternately crossed, so as to produce a raised pattern.

Kue and Cry. In Law, the common process of pursuing a felon. This custom is of ancient origin, and evidently arose from the practice of pursuing the offender with a loud outcry, that all might try to bring him to justice.

Huguenots. In French History, a name given in the sixteenth century to the Protestants or Calvinists of France. The writers of that time were not acquainted with the true derivation of this popular nickname, to which they assigned various absurd etymologies; it is, undoubtedly, a corruption of the German *Eidgenossen*, signifying the Swiss confederates. Geneva was the literary and ecclesiastical metropolis of the French reformed; and consequently they were naturally confounded, in the eye of the Catholic populace, with the Swiss, who supported that republic by their alliance. After a long period, during which they increased in numbers in spite of occasional persecution (under Francis I. and Henry II.), a large party of the Huguenots took part in the conspiracy of Amboise in 1560; and although the free exercise of their religion was secured to them by the edict of January 1562, yet they were driven by the violations of that edict to take up arms against the government of Francis II. in the same year. At that period their leaders were of the houses of Bourbon (king of Navarre and prince of Condé) and Chatillon (the Admiral Coligny). They were powerful in numbers, and still more in wealth and consequence. A very large proportion of the higher nobility, and of the middle nobility and gentry, especially in the central and south-western parts of France, the whole or greater part of the population in some towns, as Rouen, La Rochelle, Dieppe, Nismes, and, finally, a large body among the peasantry in some districts, especially of the south, where

the doctrines of the Albigeois were never fully extinguished, belonged to their party. But during the religious wars of the sixteenth century they gradually lost ground under the increasing zeal and fanaticism of the great Catholic body; and after the conversion of Henry IV. most of their chiefs among the nobility successively abandoned the faith. They sustained two civil wars in the following century against Louis XIII., which cost them the loss of the strong places which they had held, and of many of their privileges. The history of the Protestant church in France then ceased to be the history of a political party; and the name of Huguenots, about the same time, began to pass out of ordinary use. De Thou, Davila, D'Aubigny, Lanoue, are perhaps the most valuable of the many contemporary historians of the sixteenth century. Among modern compilations, see Smedley's *History of the Religious Wars of France*; Sismondi, vols. xvi. to xx.; Michelet, '*Guerres de Religion*,' a division of his *History of France*; Browning's *History of the Huguenots from the Edict of Nantes, 1539*.

Huissier (Fr. from the old word *huis*, a door; whence our *usher*). Executive officers in the French courts of justice, whose original function was to keep the door of the tribunal. Such officers were styled by the Romans *apparitores*, *cohortales*, *executores*, and by a variety of other names. In France the huissiers were originally a subdivision of the general class of *servientes*, *sergens*; but afterwards the latter came to be called indiscriminately *huissiers*. Their functions are now numerous and important. They give notice on behalf of and execute the processes of the courts to which they are attached, both civil and criminal. Those of the Court of Cassation are appointed by itself; those of the *cours d'appel* and other tribunals by the government. The officers termed *huissiers-priseurs*, or *commissaires-priseurs*, are employed as appraisers at public sales. (Bouillet, *Dictionnaire Universel*.)

Hulk. The name given to old ships laid by as unfit for further seagoing service, and used as dépôts for coal, sailors, &c. The hulks near Woolwich consisted formerly of old ships to which convicts were sent previously to their departure from the country.

Hull. The body of a ship, exclusive of the masts, rigging, &c.

Hull down expresses that the hull of the ship is concealed by the convexity of the sea.

Humanitarian (Lat. *humanitas*). A term sometimes applied to those who deny the divinity of Christ, and assert Him to have been mere man. This, however, is more than the word exactly signifies; and the term Philanthropist, or mere Humanitarian, has been suggested as conveying the idea more precisely. [SOCINIAN; UNITARIAN.]

Humanities (Lat. *humanitas*). A word employed until lately in European schools and colleges of various nations, to signify grammar,

HUMBLE BEE

rhetoric, and poetry, including the study of the ancient classics. It may be regarded as synonymous with polite literature. A student in humanities (literæ humaniores) was termed a *humanist*.

Humble Bee. [MELLIFERA.]

Humboldtine (so called in honour of Baron Humboldt). A native oxalate of iron. It occurs in yellow capillary crystals, also botryoidal, fibrous, granular, or earthy.

Humerus (Lat.). The bone of the arm. The first of the radiated system of bones of the anterior extremity, articulated with the scapula in the vertebrated animals. In Entomology, Mr. Kirby so calls the third joint of the anterior pair of legs in Hexapod insects.

Humic Acid or **Humine** (Lat. humus, *the ground*). The peculiar brown matter which may be obtained from bog-earth, peat, and turf, and which may also be extracted from most soils, where it is derived from the slow decay of plants; it is also contained in brown decayed wood, and in the brown exudations of the bark of certain trees, more especially in that of the elm, or *ulmine*. By the action of several chemical agents on different organic bodies, a similar substance is frequently produced. It contributes to the fertility of soil, chiefly, perhaps, in consequence of its absorptive power in regard to ammonia.

Humifusus (Lat. humus, *the ground*, and fundo, *I pour or spread out*). In Botany, denotes the spreading of plants over the surface of the ground: procumbent.

Humiriaceæ (Humirium, one of the genera). A natural order of arborescent or shrubby Exogens, placed by Lindley in the Erical alliance, and inhabiting Brazil, but not very well understood. They differ from *Meliaceæ* in their albuminous seeds and their slender embryo; agreeing in the latter respect, and in their balsamic wood, with *Styracææ*. *Humirium floribundum* yields, on being wounded, a liquid yellow balsam, called Balsam of Umiri, somewhat resembling Balsam of Tolu. *H. balsamiferum* also yields a balsam used for perfumery and in medicine.

Humite. A variety of Chondrodite, named in honour of Sir Abraham Hume, in whose collection it was first noticed as a distinct species. It occurs in minute shining crystals, generally of a yellowish or deep reddish-brown colour, in ejected masses of a granular or crystalline rock on Monte Somma. [CHONDRODITE.]

Humming Bird. [TROCHILUS.]

Hummock. A level sheet of ice. A circular mound seen at a distance is also so called.

Humoral Pathology. The doctrine which refers disease to a morbid condition of the humours or fluids of the body, as opposed to *nervous pathology*, which refers them to the nervous energy resident in the solids.

Humour. [WIT.]

Humours of the Eye. [EYE.]

Humulus (Lat. humus, *the earth*). The Common Hop is the *Humulus Lupulus* of botanists. [HOP.]

HURAUITE

Hundred (connected with Lat. centum). A hundred is a territorial division, having for its object the more convenient and efficient administration of justice; anciently subsisting in other countries, particularly France and Lombardy, as well as in England, and adopted in this country as the subdivision of a county. The institution of the hundred, as well as that of the county and tything, is, upon no precise authority, usually referred to the reign of Alfred; but it is probable that the division was of an older date, and that it was not introduced into all parts of England at the same time. Having originated in the south, it was subsequently applied to the divisions previously established in the northern counties under the name of *wapentakes*. To each hundred belonged a court baron, similar in the nature and extent of its jurisdiction to the county court, and also a court leet [LEET]; both of which were usually, and by the common law, held either by the sheriff, or by a deputy or steward having authority under him. But in some cases the jurisdiction of the court baron and court leet, or of one of them, within the hundred, was by special grant of the crown vested in private persons, and exercised by them or their deputies. The essential use of the hundred was in the liability of the hundreders, when offences were committed within their district, either to produce the offender, or make good the damage. This liability, much restricted by statute, still subsists in certain cases of riotous and wilful mischief.

Hundredweight. A denomination of weight containing 112 pounds. It is subdivided into 4 quarters, each containing 28 pounds. [WEIGHTS.]

Hunger (Ger.). The sensation in the region of the stomach arising from the want of solid food: in intensity it varies considerably in different individuals, and is sometimes attended by pain and windy rumblings in the epigastrium. When severe, hunger is attended by slow respiration and circulation, and diminution of the heat of the body and of the secretions. The return of hunger is accelerated by exercise and fatigue, and by a low temperature. In debilitated constitutions excessive hunger should be carefully avoided; and in any case, the effects of fasting may prove prejudicial to the functions of the stomach.

Hunters. *Venantes*. A tribe of spiders are so called which are incessantly running or leaping about in the vicinity of their abode, to chase and seize their prey.

Hura (the South American name). The Sandbox-tree, *H. crepitans*, indigenous in South America, grows thirty to forty feet high, and produces hard-shelled furrowed fruit as large as an orange, which when ripe and exposed to a dry atmosphere bursts with a loud sharp crack like the report of firearms. A purgative oil is obtained from the seeds; and a venomous milky juice abounds in all parts of the plant.

Huraulite. A phosphate of iron and manganese found at Huraux, in the Haute Vienne.

weight of metal, than guns of the same calibre. [ORDNANCE.]

Hoy (Dutch, huy). A small vessel having generally one mast, and ordinarily used for the carriage of luggage to and from larger vessels and the shore.

Hubert, Order of Saint. The highest Bavarian order of knighthood, founded in 1444.

Hucho. A species of trout (*Salmo Hucho*) found in the Save, Laybach, and other rivers tributary to the Danube: it attains a weight of about three pounds. 'The skin of this fish is thick; the scales smaller than those of the common trout, and the pectoral fin has four spines more, which I think enables it to turn with more rapidity. Fried or roasted, he is a good fish; his flesh is white, but not devoid of curd, and though rather softer than that of a trout, I have never observed in it that muddiness or peculiar flavour which sometimes occurs in trout even in perfect season.' (Davy's *Salmonia*.)

Huckaback (Teut. huycke, a covering). A coarse table linen or towelling, having the web alternately crossed, so as to produce a raised pattern.

Hue and Cry. In Law, the common process of pursuing a felon. This custom is of ancient origin, and evidently arose from the practice of pursuing the offender with a loud outcry, that all might try to bring him to justice.

Huguenots. In French History, a name given in the sixteenth century to the Protestants or Calvinists of France. The writers of that time were not acquainted with the true derivation of this popular nickname, to which they assigned various absurd etymologies; it is, undoubtedly, a corruption of the German *Eidgenossen*, signifying the Swiss confederates. Geneva was the literary and ecclesiastical metropolis of the French reformed; and consequently they were naturally confounded, in the eye of the Catholic populace, with the Swiss, who supported that republic by their alliance. After a long period, during which they increased in numbers in spite of occasional persecution (under Francis I. and Henry II.), a large party of the Huguenots took part in the conspiracy of Amboise in 1560; and although the free exercise of their religion was secured to them by the edict of January 1562, yet they were driven by the violations of that edict to take up arms against the government of Francis II. in the same year. At that period their leaders were of the houses of Bourbon (king of Navarre and prince of Condé) and Chatillon (the Admiral Coligny). They were powerful in numbers, and still more in wealth and consequence. A very large proportion of the higher nobility, and of the middle nobility and gentry, especially in the central and south-western parts of France, the whole or greater part of the population in some towns, as Rouen, La Rochelle, Dieppe, Nismes, and, finally, a large body among the peasantry in some districts, especially of the south, where

the doctrines of the Albigeois were never fully extinguished, belonged to their party. But during the religious wars of the sixteenth century they gradually lost ground under the increasing zeal and fanaticism of the great Catholic body; and after the conversion of Henry IV. most of their chiefs among the nobility successively abandoned the faith. They sustained two civil wars in the following century against Louis XIII., which cost them the loss of the strong places which they had held, and of many of their privileges. The history of the Protestant church in France then ceased to be the history of a political party; and the name of Huguenots, about the same time, began to pass out of ordinary use. De Thou, Davila, D'Aubigny, Lanoue, are perhaps the most valuable of the many contemporary historians of the sixteenth century. Among modern compilations, see Smedley's *History of the Religious Wars of France*; Sismondi, vols. xvi. to xx.; Michelet, 'Guerres de Religion,' a division of his *History of France*; Browning's *History of the Hugonots from the Edict of Nantes, 1589*.

Huissier (Fr. from the old word huis, a door; whence our *usher*). Executive officers in the French courts of justice, whose original function was to keep the door of the tribunal. Such officers were styled by the Romans *apparitores, cohortales, executores*, and by a variety of other names. In France the huissiers were originally a subdivision of the general class of *servientes, sergens*; but afterwards the latter came to be called indiscriminately *huissiers*. Their functions are now numerous and important. They give notice on behalf of and execute the processes of the courts to which they are attached, both civil and criminal. Those of the Court of Cassation are appointed by itself; those of the *cours d'appel* and other tribunals by the government. The officers termed *huissiers-priseurs*, or *commissaires-priseurs*, are employed as appraisers at public sales. (Bouillet, *Dictionnaire Universel*.)

Hulk. The name given to old ships laid by as unfit for further seagoing service, and used as dépôts for coal, sailors, &c. The hulks near Woolwich consisted formerly of old ships to which convicts were sent previously to their departure from the country.

Hull. The body of a ship, exclusive of the masts, rigging, &c.

Hull down expresses that the hull of the ship is concealed by the convexity of the sea.

Humanitarian (Lat. humanitas). A term sometimes applied to those who deny the divinity of Christ, and assert Him to have been mere man. This, however, is more than the word exactly signifies; and the term Philanthropist, or mere Humanitarian, has been suggested as conveying the idea more precisely. [SOCINIAN; UNTARIAN.]

Humanities (Lat. humanitas). A word employed until lately in European schools and colleges of various nations, to signify grammar,

HUMBLE BEE

rhetoric, and poetry, including the study of the ancient classics. It may be regarded as synonymous with polite literature. A student in humanities (literæ humaniores) was termed a *humanist*.

Humble Bee. [MELLIFERA.]

Humboldtine (so called in honour of Baron Humboldt). A native oxalate of iron. It occurs in yellow capillary crystals, also botryoidal, fibrous, granular, or earthy.

Humerus (Lat.). The bone of the arm. The first of the radiated system of bones of the anterior extremity, articulated with the scapula in the vertebrated animals. In Entomology, Mr. Kirby so calls the third joint of the anterior pair of legs in Hexapod insects.

Humic Acid or Humine (Lat. humus, the ground). The peculiar brown matter which may be obtained from bog-earth, peat, and turf, and which may also be extracted from moist soils, where it is derived from the slow decay of plants; it is also contained in brown decayed wood, and in the brown exudations of the bark of certain trees, more especially in that of the elm, or *ulmine*. By the action of several chemical agents on different organic bodies, a similar substance is frequently produced. It contributes to the fertility of soil, chiefly, perhaps, in consequence of its absorptive power in regard to ammonia.

Humifusus (Lat. humus, the ground, and fundo, I pour or spread out). In Botany, denotes the spreading of plants over the surface of the ground: procumbent.

Humiferae (Humirum, one of the genera). A natural order of arborescent or shrubby Exogens, placed by Lindley in the Erical alliance, and inhabiting Brazil, but not very well understood. They differ from *Meliaceae* in their albuminous seeds and their slender embryo; agreeing in the latter respect, and in their balsamic wood, with *Styracae*. *Humirum floribundum* yields, on being wounded, a liquid yellow balsam, called Balsam of Umiri, somewhat resembling Balsam of Tolu. *H. balsamiferum* also yields a balsam used for perfumery and in medicine.

Humite. A variety of Chondrodite, named in honour of Sir Abraham Hume, in whose collection it was first noticed as a distinct species. It occurs in minute shining crystals, generally of a yellowish or deep reddish-brown colour, in ejected masses of a granular or crystalline rock on Monte Somma. [CHONDRODITE.]

Humming Bird. [TROCHILUS.]

Hummock. A level sheet of ice. A circular mound seen at a distance is also so called.

Humoral Pathology. The doctrine which refers disease to a morbid condition of the humours or fluids of the body, as opposed to *nervous pathology*, which refers them to the nervous energy resident in the solids.

Humour. [WIT.]

Humours of the Eye. [EYE.]

Humulus (Lat. humus, the earth). The Common Hop is the *Humulus Lupulus* of botanists. [HOP.]

HURAUITE

Hundred (connected with Lat. centum). A hundred is a territorial division, having for its object the more convenient and efficient administration of justice; anciently subsisting in other countries, particularly France and Lombardy, as well as in England, and adopted in this country as the subdivision of a county. The institution of the hundred, as well as that of the county and tything, is, upon no precise authority, usually referred to the reign of Alfred; but it is probable that the division was of an older date, and that it was not introduced into all parts of England at the same time. Having originated in the south, it was subsequently applied to the divisions previously established in the northern counties under the name of *wapentakes*. To each hundred belonged a court baron, similar in the nature and extent of its jurisdiction to the county court, and also a court leet [LEET]; both of which were usually, and by the common law, held either by the sheriff, or by a deputy or steward having authority under him. But in some cases the jurisdiction of the court baron and court leet, or of one of them, within the hundred, was by special grant of the crown vested in private persons, and exercised by them or their deputies. The essential use of the hundred was in the liability of the hundreders, when offences were committed within their district, either to produce the offender, or make good the damage. This liability, much restricted by statute, still subsists in certain cases of riotous and wilful mischief.

Hundredweight. A denomination of weight containing 112 pounds. It is subdivided into 4 quarters, each containing 28 pounds. [WEIGHTS.]

Hunger (Ger.). The sensation in the region of the stomach arising from the want of solid food: in intensity it varies considerably in different individuals, and is sometimes attended by pain and windy rumblings in the epigastrium. When severe, hunger is attended by slow respiration and circulation, and diminution of the heat of the body and of the secretions. The return of hunger is accelerated by exercise and fatigue, and by a low temperature. In debilitated constitutions excessive hunger should be carefully avoided; and in any case, the effects of fasting may prove prejudicial to the functions of the stomach.

Hunters. Venantes. A tribe of spiders are so called which are incessantly running or leaping about in the vicinity of their abode, to chase and seize their prey.

Hura (the South American name). The Sandbox-tree, *H. crepitans*, indigenous in South America, grows thirty to forty feet high, and produces hard-shelled furrowed fruit as large as an orange, which when ripe and exposed to a dry atmosphere bursts with a loud sharp crack like the report of firearms. A purgative oil is obtained from the seeds; and a venomous milky juice abounds in all parts of the plant.

Huraulite. A phosphate of iron and manganese found at Huraux, in the Haute Vienne.

HURDLE

Hurdle (Dutch horde, Ger. *hürde*). A frame made of wood or iron, for the purpose of forming temporary fences. The frame consists of two perpendicular stakes, into which are fixed five or six horizontal bars, and the whole is braced together by one or two diagonal pieces. When a fence is to be formed, the hurdles are put down end to end; they are made fast to the ground by the insertion of the lower end of the stakes into it, and to one another by a tie fastened round their upper ends, or by a movable wooden pin passed through them.

Huronite. A name given to certain radiated articulated bodies formerly referred to the *Polyparia*, found in the transition limestone of Lake Huron. (*Geol. Trans.* vol. i. new series.)

Huronite. A mineral from the vicinity of Lake Huron; it occurs embedded in black Hornblende, and is a hydrated silicate of alumina, lime, magnesia, and protoxide of iron.

Hurricane (Span. *huracan*, an American word). A violent storm, generally accompanied by thunder and lightning, and distinguished from every other kind of tempest by the vehemence of the wind, and the sudden changes to which it is subject. Hurricanes prevail chiefly in the East and West Indies, the Isle of France, and in some parts of China. [STORM; TORNADO.]

Hurst (A.-Sax.). A wood; hence the termination of the names of several places in England, particularly in Kent and Sussex.

Hurter (Fr. *heurtoir*). In Artillery, a piece of timber placed along the head of a gun platform, at the foot of the interior slope of the parapet, to prevent the latter from being injured by the wheels of the gun-carriage.

Husbandry. A comparatively primitive term, including both agriculture and gardening, or all those country occupations which the father of a family was expected to perform in the country. The term is now commonly used as synonymous with agriculture. The *Berwickshire husbandry*, the *convertible husbandry*, are terms used in agriculture for certain systems of cropping in which the land is alternately kept under grass and tillage.

Hussars. A kind of light cavalry, used in all the armies of Europe. The term is of Hungarian origin (being derived from *husz*, twenty, and *ar*, pay, every twenty houses furnishing one man), and was first applied to the body of troops raised by the nobles of Hungary on occasion of the appeal made to the latter in 1453 by Matthias Corvin. Their arms consist of a sabre, a carbine, and a pair of pistols. In the British cavalry there are thirteen regiments of hussars. [CAVALRY.]

Hussites. The followers of John Huss, a Bohemian reformer and divine, who was convicted of heresy by the council of Constance, and burnt by order of the emperor of Germany, in 1415. The writings of Huss and Jerome of Prague were the source from which Luther drew a great part of his opinions and views; but it was from the books of Wiclif that Huss was himself induced to institute his enquiries into

HUSTINGS

the faith and morals of the church. The errors charged against him contain many of the opinions now held by all Protestants; but several of these he himself denied, and those for which he ultimately suffered have not been universally held by reformers, nor do they seem of very great importance. They were these: 1. That Pope Sylvester and the emperor Constantine did evil to the church when they enriched it. 2. That if any ecclesiastic be in a state of mortal sin, he is disqualified for the administration of the sacraments. 3. That tithes are not dues, but merely eleemosynary. On the other hand, he held the Romish idea of transubstantiation; and the opinion of the necessity of communion in both kinds, which became afterwards the most remarkable feature in the doctrines of the Hussites, is not in reality to be ascribed to their founder. The condemnation of Huss is also remarkable, as it is from the circumstances attendant on it that the imputation of not keeping faith with heretics is originally charged upon the Roman church. The emperor Sigismund gave Huss a safe-conduct, to secure him from any ill consequences that he might apprehend from delivering himself up voluntarily to be examined by the council. Nor did the council assert any right to condemn him. They handed him over to the secular arm, to the emperor himself. But it is confidently asserted that when the emperor scrupled to violate a promise which was undoubtedly binding upon him, it was at the pressing instance of the pope or cardinals that he allowed the execution to take place. Their apologists affirm that this safe-conduct imported only that Huss might go to Constance without being harmed; the words of the original instrument, however, are reported to be, *Transire, stare, morari, redire libere permittatis*. (Milman, *History of Latin Christianity*, book xiii.)

After the execution of Huss, and of his disciple Jerome in the following year, there arose a violent insurrection among their partisans in Bohemia, who maintained themselves for many years by force of arms, and split into two sects, under the denominations of the Calixtines and the Thaborites. The former, so called from demanding the cup in the sacrament, were finally reconciled to the church by the concession which they required. The latter were so called from the name they gave to the hill on which they pitched their camp in the neighbourhood of Prague, and carried their notions upon the authority of the church and its ministers, ceremonies, and all the externals of religion, to the length of an extreme simplicity. The Bohemian Brothers and the Beghards, who gave so great an impulse to the Reformation, were the descendants of this branch of the Hussites. (Cochlæus, *Hist. Hussitarum*; Gieseler's *Tract-book*, iii. 355, translation.)

Hustings (probably from A.-Sax. *hus*, house, and *ting*, court or judgment). The principal court of the city of London, held before the lord mayor and aldermen: also, in common language, the booth or elevated place on which

candidates at a parliamentary election are proposed, and address their constituents.

Hutchinsonians. The name given to those who embraced the opinions of John Hutchinson, a philosopher and naturalist of the eighteenth century. The chief characteristics of Hutchinson's philosophy consist in his rejection of Newton's doctrine of gravitation; and in his maintaining the existence of a plenum on the authority of the Old Testament, which according to him embraces a complete system of natural philosophy as well as of religion. (See his works, 12 vols. 8vo. 1748.)

Hyacinth (Gr. Ὕακινθος). In Botany, the name of a popular spring flower, *Hyacinthus orientalis*, of which numerous garden varieties, chiefly with blue, red, or white blossoms, are cultivated. To the same genus belongs the common Harebell, *Hyacinthus non scriptus*.

HYACINTH. In Mineralogy, the term Hyacinth or Jacinth is applied to the transparent bright varieties of Zircon, which differ from Jargon merely in their red colour.

Hyacinthine. [MEIONITE.]

Hyacinthus (Gr. Ὕακινθος). In Mythology, the son of Amyclas king of Laconia, accidentally killed by Apollo, who immortalised his favourite by causing the flower which still bears his name to spring from his blood, and inscribing the word AI on its leaves, to indicate the deep grief of the god for his loss. An annual festival, named Hyacinthia, was celebrated at Amyclæ in honour of Hyacinthus. (*Athen. Deipn.* iv. p. 139.)

Hyades (Gr. Ὕαδες, from ἔβην, to rain). In Mythology, the daughters of Atlas and Æthra, who, overwhelmed with grief at the death of their brother Hyas, wept so violently that the gods took them into heaven, where they still continue to weep, and are thence supposed to prease rain. They form a cluster of five stars in the face of Taurus.

Hyæna (Gr. Ὕανα). A genus of digitigrade Carnivorous Mammals, separated by Storr from the *Canis* of Linnæus, from which it not only differs in dentition and other important particulars, but, in general, manifests a closer affinity with the *Viverridæ*; between which and *Felis* the genus *Hyæna* is placed by Cuvier. The characters of this genus are: five molars above and four below, on each side, the three anterior molars being conical, smooth, and remarkably large, adapted for breaking the bones of their prey; the tongue has a broad patch of cuticular spines on the anterior part of its dorsum; the legs are each terminated by four claws; there is a peculiarly large perineal glandular pouch; and the neck and jaws are remarkable for the strength of their muscles. The species of hyæna are nocturnal; they prey on dead carcases. An extinct species (*Hyæna spelæa*) was abundant in England and France anterior to the glacial epoch, and has left its remains in many caverns in both countries.

Hyænancho (Gr. Ὕανα, *hyæna*, and ἔρχομαι, *I strangle*). A Euphorbiaceous plant, used at the Cape of Good Hope for poisoning hyænas,

and hence called the Hyæna-poison. The species is *H. capensis*. It is used by sprinkling the powder of its fruit on raw flesh, which is left in the places which the animals frequent.

Hyænodes (Gr. Ὕανα, and ὀδούς, *tooth*). A genus of *Carnivora*, about the size of a leopard, which has left its remains in the upper eocene strata of Hordwell in Hampshire. It presents the typical dihyodont dentition of forty-four teeth. [DIHYODONT.]

Hyalæa (Gr. ὕαλος, *glass*). A genus of beautiful Pteropodous Molluscs, remarkable for the delicacy and transparency of the shell. This bears a close resemblance to a bivalve, with the two valves unequal and soldered together at the hinge. That portion of the shell which corresponds to the ventral aspect of the animal is convex; the dorsal plate is nearly flat, and is longer than the other; the hinder or closed margin of the shell is produced into three sharp points. The inhabitant is provided with two large wing-like processes of the mantle, which it protrudes, when swimming, from the anterior open fissure of the shell. The species are found floating in the Mediterranean and tropical seas.

Hyalite (Gr. ὕαλος; λίθος, *a stone*). A yellow or grey variety of uncleavable Quartz or Opal; it is commonly concretionary or chalcidonic, of a vitreous fracture and lustre. It occurs in trap-rocks in grains, filaments, and botryoidal masses resembling colourless glass: it is silica combined with about 6 per cent. of water.

Hyaloid (Gr. ὕαλος, and εἶδος, *form*). A term applied to transparent membranes, and more particularly to that which invests the vitreous humour of the eye.

Hyalosiderite (Gr. ὕαλος, and σίδηρος, *iron*). A mineral consisting essentially of the silicates of magnesia and iron, from Saabach, in the Brisgau. It is of a glassy lustre, and is a variety of Chrysolite.

Hybernaculum (Lat.). A term applied by Linnæus to denote a leaf-bud; which he rightly considered the winter-quarters of the point of growth in a plant.

Hybernation (Lat. hibernus, *wintery*). The act by, or the state in, which certain animals exist during that season of the year when excess of cold or of heat, or lack of food, prevents their going abroad and performing their customary functions. As this state is generally superinduced by the rigours of winter, it has received its denomination from that circumstance; but in the tropics the effects of the hottest and driest weather, in reducing the numbers of the insect world, are such as to render it necessary for many reptiles and some insectivorous mammals, as the *Tenrecs*, to pass into a state of inactivity or torpidity, in order to maintain life until the recommencement of the rainy season. The condition of hybernation is, in fact, less the alteration of temperature, than the abstraction of the means of subsistence dependent thereon; as, e.g., the disappearance of insects in the winter season of our own climate.

Animals so highly organised as the warm-

HYBERNATION

and quick-breathia alia

ed organic machinery in action without frequent supplies of food; an interruption in this respect of a few days, or at most a few weeks, is fatal. If, therefore, the phenomenon of hybernation had been known only in the cold-blooded classes, an insectivorous mammal in a climate where insects could not subsist for several months in the year would be inconceivable. The modification of the vital powers by which a warm-blooded animal is made even temporarily to assume the state and properties of a reptile, is perhaps one of the most striking instances of special adaptations to meet an exceptional case that the history of animals presents. When the atmosphere becomes vacant of insect life, when the bat, in its nocturnal fittings, would vainly traverse it in search of food, and when the few insects that survive the winter have burrowed too deeply in the earth, or concealed themselves in hiding-places too secure for the reach of the hedgehog—these species, with starvation staring them in the face, are preserved by the suspension of those functions the maintaining of which in a state of activity is essentially dependent on an uninterrupted supply of nutriment. The bat suspends itself in the innermost recesses of its cave, the hedgehog creeps to its concealed nest, and both resign themselves to deep repose; but the breathing becomes gradually slower than in ordinary sleep, the pulsations of the heart diminish in force and frequency, the supply of stimulating arterial blood to the muscles and the brain is progressively reduced, relaxation of the muscular fibres is converted into stiff inaction, and sleep sinks into stupor: at length respiration entirely ceases, and with it those chemical changes in the capillary circulation on which animal heat mainly depends. The preservation of life, in its passive or latent state, is now due to the irritable property of the heart's fibre, which is excited to contract by the present dark or carbonised state of the blood, and continues to propel it slowly over the torpid frame during the whole period of hybernation. This slow circulation of venous blood through both the pulmonic and systemic vessels is the only recognisable vital act during that period, and the material conveyed by the absorbents into the circulating fluid is sufficient to counterbalance the slight waste thus occasioned. So long, therefore, as the state of torpidity continues, the hedgehog and bat are independent of supplies from without, but they purchase that independence by a temporary abrogation of their vital faculties.

The hybernation of lizards, snakes, frogs, toads, and other cold-blooded reptiles, is accompanied by analogous changes, differing only in degree; for as the heart in these animals is, at all times, destined to propel blood imperfectly oxygenated—as the respiratory or oxygenating apparatus is imperfect—and as the heat of the body in them rises and falls with the external temperature, a slight

HYBRID

deterioration of these lower conditions of the circulating and respirator, functions induces torpidity, with the consequent loss of appetite and independence of food. Some quadrupeds, as the dormouse and squirrel, which subsist on articles of diet better adapted to be laid up in store than insects, carry a winter provision to their hybernating nests; and their torpidity is more nearly allied to a profound but ordinary sleep; respiration is never wholly suspended; the waste of the organism is proportionate to the degree of activity in the working of the machine, and they occasionally rouse themselves and take in the requisite supply from their provident store. Insectivorous birds, being independent, through their power of traversing space, of the vicissitudes of climate and their consequences, transport themselves, when their food fails in one country, to latitudes favourable to its abundance: hence the immigration of the cuckoo and swallow at the commencement of the genial season, and their subsequent disappearance.

Xyrodonts (Gr. *ὀδὸς*, *gibbous*, and *ὀδός*, *tooth*). A family of Plagiostomous fishes found in all the secondary rocks from the trias to the chalk inclusive. The teeth of the xyrodonts are conical, but broader and less sharp than those of true sharks. The enamel is strongly marked by longitudinal grooves and folds. One cone is larger than the rest, and called the *principal*; the others are *secondary*.

Hybrid (Lat. *hybrida*). The produce of a female plant or animal which has been impregnated by a male, of a different variety, species, or genus.

The most common hybrids are those which result from the connection of different varieties of the same species, as the produce of the wild boar and domestic sow; the endless modifications which result from analogous interbreeding from varieties of the rose and other ornamental or useful plants are familiar examples of the principle among vegetables.

Specific hybrids have been produced by Kölreuter from the artificial fertilisation of the *Nicotiana rustica* with the pollen of the *Nicotiana paniculata*; and it has been ascertained by numerous observations, that a multitude of plants produce specific hybrids in a state of nature. Naudin has lately been occupied in hybridising gourds, and his researches are published in the *Annales des Sciences Naturelles*.

Hybrids from different species of insects, under similar circumstances, have been obtained; as from the connection of *Papilio Jurtina* with *P. Janira*, of *Chrysomela aenea* with *Chr. alni*, of *Phalangium cornutum* with *Ph. Opilio*. Specific hybrids have been obtained in the class of fishes by artificial impregnation between the *Cyprinus Carpio* and *Cypr. Carassias*, and between the *Cypr. Carpio* and *Cypr. Gibelio*. In birds, hybrids have been bred between the goldfinch and canary, between the reeves and the common pheasant—the pheasant and the common fowl—the swan (*Anas Olor*, Linn.) and the goose (*Anas Anser*, Linn.)—between the *Tetrao*

HYBRID

Tetriz and *Tetrao Urogallus*—between the *Corvus Corone* and *Corvus Cornix*, &c. Among Mammals, hybrids have been produced between the lion and tiger, the dog and wolf, the dog and jackal, the dog and fox, the goat and ibex, the horse and zebra, the zebra and ass, and the horse and ass; the produce of the two last species, as it is the most common and useful of hybrids, being termed *par excellence* the mule.

But a fruitful connection is not only possible between individuals of different varieties or of distinct species, but also occasionally between animals of different genera. General hybrids have thus resulted from the union of the goat (*Capra Hircus*) with the antelope (*Antelope Rupicapra*), of the stag with the cow, and of the bull with the sheep, notwithstanding their disparity of size. Among reptiles, between the toad (*Bufo*) and the frog (*Rana*); among insects, between *Cantharis melanura* and *Elatér niger*, and between *Melolontha agricola* and *Cetonia hirta*. Experiment alone can determine the amount of affinity beyond which fertilisation is impracticable, but at present it seems to be restricted to individuals belonging to genera of the same natural group.

The tendency of all the natural phenomena relating to hybridity is to prevent its taking place, and when it has occurred to arrest the propagation of varieties so produced, and to limit their generative powers so as to admit only of reversion to the original specific forms.

It would seem that in most cases the fertilising particles had a specific power over the ova derived from the same species, or were attracted by them in a peculiar manner; for the milt and roe of different species of fishes are not unfrequently excluded in the same locality, yet hybrids are not met with in consequence. Spallanzani was not able to impregnate the ova of the frog with the semen of the newt, nor to produce a fertile combination of those of the toad and newt; nor did the injection of the semen of the dog into the vagina of the cat impregnate any of her ova.

The individuals of different species which produce a hybrid offspring do not voluntarily copulate. The salacious mare must be blindfolded, or she will not receive the ass. The stallion refuses to mount the she-ass, if a mare be in sight. Hunter states that, when he desired 'to have a she-wolf lined by some dog, she would not allow any dog to come near her, but was held while a greyhound dog lined her; while in conjunction she remained pretty quiet, but when at liberty endeavoured to fly at the dog.' Buffon reared puppies of the wolf, fox, and dog together, to familiarise them with each other; but when they were in heat, the females of each species exhibited an insurmountable repugnance to the male of the others, and mortal combats ensued instead of fertile union between the different sexes of the different species. (*Annales du Muséum*, t. xii. p. 119.)

In a few exceptional cases, serving only to establish the rule of their infertility, specific

HYDATIDS

hybrids have been known to propagate together, and produce a degenerate intermediate race, which soon becomes extinct; it more commonly happens that a hybrid is sterile, or propagates only with an individual of pure breed.

On the assumption that a hybrid produced by two individuals of undoubtedly distinct species is sterile, experiments have been made on the breeding powers of hybrids, to determine the nature of doubtful species. Thus Hunter believed that he had obtained absolute proof of the jackal being a dog, and to have equally made out the wolf to be of the same species; and he then proceeds to speculate whether the wolf is from the jackal, or the jackal from the wolf; for he had obtained pups from the connection of a female hybrid jackal-dog and a male terrier, and between a female hybrid dog-wolf and a male greyhound; and he adds, in respect of the latter fact, that 'it would have equally proved the same fact if she had been lined either by a wolf, a dog, or one of the males of her own litter.' (Hunter's *Animal Economy*, by Owen, 8vo. p. 323.) But this assertion, that the fertility of a hybrid with an individual of a pure breed proves the fact of the identity of two supposed distinct species equally with the production of offspring from the connection of hybrid with hybrid, cannot be admitted. To prove the identity of two supposed distinct species, on the assumption that the fertility of the hybrids from the two gives the proof required, it should be shown that such hybrids are fertile among themselves, and capable of propagating indefinitely an intermediate variety. Hunter's celebrated experiments, however, only proved that two nearly allied species will produce a hybrid offspring, and that such hybrid may be impregnated by an individual of the pure breed; but this fact illustrates the general law by which the reversion of the hybrid to the pure breed is provided for; while, on the other hand, the intermixture of distinct species is guarded against by the aversion of two specifically different individuals to sexual union.

Hydarthrus (Gr. *ὕδωρ*, and *ἄρθρον*, a joint). The *white swelling*. The joints most subject to it are the knee, elbow, wrist, and ankle. It is distinguished from rheumatic swelling of the joints by a fixed and wearing pain preceding the tumefaction, and often existing for a long time before any enlargement of the part is perceptible: also by the general state of the habit.

Hydatids (Gr. *ὕδωρ*, a bladder). A term somewhat vaguely applied both to morbid cysts and true Entozoons of the order *Cystica*. Of the latter some are globular, with a tunic composed of a double albuminous membrane between which the sporules or ova are developed. In the species developed in the human liver, the ova are detached from the internal surface, and it is hence termed *Acephalo-cystis endogena*. In a species infesting similar organs in the lower animals the ova are detached from the external surface, and it is called *Acephalo-cystis exogena*. In a higher organised genus

HYDE

of Hydatids, a slender and more or less elongated process is continued from the cyst, and terminates in an extremity provided with suckers and a coronet of recurved hooklets, like the head of a tapeworm: this genus is termed *Cysticercus*. Another genus has numerous similarly organised appendages attached to the cyst, and is accordingly termed *Cenurus*. A hydatid of the last genus is developed in the brain of sheep, and produces the *giddy sickness* or *staggers*. [ACERHALOCYST.]

Hyde or Hide. A measure of land common in Domesday Book and old English charters. The derivation of the name is fancifully traced to the ancient fable (common to many nations) of the deceit practised by a colonist in acquiring from the owners so much land as he could cover with the hide of an ox, and then dividing it into strips so as to make it extend over a large space. Its contents are also uncertain, but are stated by some authorities to amount to 100 Norman or 120 English acres. (Warner's *Hist. of Hampshire*; Ellis's *Introduction to Domesday*.)

Hydnocarpus (Gr. *ὑδρον*, a tuber, and *καρπός*, fruit). Of this genus of *Pangiaceæ*, one species, *H. venenata*, produces a fruit of the size of an apple, covered with a brown velvety down. This fruit is of a very poisonous character, and is used by the Cinghalese to poison fish, which is thereby rendered unfit for food. The seeds contain a considerable quantity of oil, which is used medicinally.

Hydra (Lat.; Gr. *ῥέπα*). In Astronomy, one of the ancient constellations in the southern hemisphere.

HYDRA. In Mythology, a monster, which was said to infest the lake Lerna in Peloponnesus. According to the fable, when one of its heads was cut off, it was immediately succeeded by another, unless the wound was cauterised. Heracles is said to have destroyed this monster by the constant application of firebrands to the wounds as the heads were cut off. The term *hydra* is sometimes used in a metaphorical sense for any manifold evil.

HYDRA. In Zoology, this name is restricted to a genus of minute fresh-water Polyps. The term *Hydrus* was applied by Linnæus to a genus of water-snakes.

Hydracids. Acids containing hydrogen as one of their essential elements; such as the hydrochloric acid, the hydrochloric acid, &c.

Hydragogue (Gr. *ὑδραγωγός*, conducting water). This term is generally applied to violent cathartics, which bring away a large quantity of watery secretion from the intestines.

Hydrangeaceæ (Hydrangea, one of the genera, from Gr. *ὑδρα*, and *εγγος*, a vessel). An order of perigenous Exogens of the Saxifragal alliance, the chief marks of which are the opposite exstipulate leaves, and the distinct styles. Lindley places it between *Saxifragaceæ* and *Cunoniaceæ*. Some of its species are ornamental, but of little utility. *Hydrangea Hortensis* and *H. japonica* are well-known decorative garden plants.

HYDRAULIC MORTAR

Hydrargo-chlorides. Compounds of the bichloride of mercury with other chlorides, forming a class of haloid salts.

Hydrargyllite (Gr. *ὑδρα*, Lat. *argilla*, clay). A name given to the native phosphate of alumina, under the erroneous idea that it consisted of alumina and water.

Hydrargyrum (Gr. *ὑδρα*, and *εργυρος*, silver). Quicksilver or mercury.

Hydrates. Compounds containing water as one of their proximate elements, and in definite proportion. Caustic potash is a *hydrate of potassa*, composed of 1 equivalent of potassa = 48, and 1 of water = 9. Slaked lime, which is an apparently dry white powder, is a *hydrate of lime*.

Hydraulic Danaide. In Hydrodynamics, a machine put in motion by the power obtained from a fall of water applied in a particular manner. A cylindrical trough of tin-plate is fixed to a vertical axis of iron, which passes through the middle of a hole in the bottom of the cylinder, the diameter of the hole being somewhat greater than that of the axis, so as to allow the water to escape. A drum of tin-plate, close above and below, is also fixed upon the axis, and placed within the trough; its diameter being so much less than that of the trough that a clear cylindrical space of about an inch and a half in thickness is left between the outer circumference of the drum and the inner circumference of the trough; and the bottom of the drum is also about an inch and a half from the bottom of the trough. This space between the two bottoms is divided into compartments, by diaphragms radiating from the axis to the circumference of the drum. Into the space between the two cylinders water is made to fall from a reservoir above, through one or more pipes, the ends of which are bent into a horizontal direction, so that the water escapes in the direction of a tangent to a horizontal section of the cylinders, and impinging on the interior surface of the trough, communicates a circular motion to the machine. The water between the cylinders thus acquires a centrifugal force, in consequence of which it presses against the interior surface of the trough and the diaphragms on the bottom; while, on the other hand, the action of gravity constantly tends to make it run out at the hole in the bottom. The moving power is measured by the weight of water escaping from the supply pipes multiplied into the height of the reservoir, and the useful effect by the same product diminished by half the force which the water retains when it issues from the hole in the bottom of the cylinder.

Hydraulic Mortar. Mortar which possesses the property of hardening under water is called *hydraulic mortar*. This property was ascertained by Vicat to be owing to the presence of clay in the limestone of which the mortar was made; or, in fact, to the presence of silicate of alumina in it. Vicat divided limestones into the pure limes, the moderately hydraulic, the hydraulic, and the energetically hydraulic.

HYDRAULIC RAM

The first were those which were, comparatively speaking, pure; the second had variable proportions of silicate of alumina present in the ratio of from 5 to 12 per cent.; the third showed the presence of from 12 to 20 per cent. of the silicate; the fourth from 20 to 30 per cent.; and the last was composed of variable proportions of the silicate of alumina, varying from 30 to 60 per cent., to carbonate of lime from 70 to 40 per cent.

With Portland cement, which is made of 16 parts of clay to 84 parts of limestone principally from the chalk formation, the rate of setting is influenced by the degree of heat to which the mixture has been exposed. The over-burnt portions will, for instance, be slow in setting, but attain great hardness under water; the properly burnt parts will set more rapidly, but will not be ultimately so hard as the over-burnt; while the under-burnt parts will set rapidly, but will not attain the same amount of hardness under water. The same thing occurs with every kind of hydraulic lime to a greater or less extent. [BÉTON; CEMENT.]

Hydraulic Ram or Water Ram. An ingenious hydraulic machine for raising water by means of its own impulse. The principle of its action and the mechanism of its construction may be described as follows:—

The water arriving at A from the reservoir with the velocity due to the height of the fall passes along the pipe A B, which should have an inclination of at least an inch for every two yards, escapes through an orifice C, which may be shut at pleasure by means of a valve. A reservoir F filled with air is attached by means of a cylinder, *abcd*, to the pipe A B D; in the middle of the bottom of the reservoir F is a circular orifice, to which there is adapted a short cylindrical tube, of which the extremity

E is also furnished with a valve. Another valve S serves to supply the air to the space comprised between the cylinder *abcd* and the tube E. G I H is an ascensional tube rising from the reservoir F. The water which escapes at C is carried off by the waste pipe K L.

The form of this apparatus (or perhaps its mode of action) suggested the name it has received. The pipe A B C is called the *body of the ram*; and the extremity, where the valves and the reservoir F are placed, is called its *head*. Both valves D and E are formed of hollow balls supported on muzzles, and of such a thickness of metal that they weigh about twice as much as the quantity of water which they displace.

VOL. II.

161

We may now consider the effects of the engine when in action. The water flowing through the orifice C acquires the velocity due to the height of the fall, and raises the ball D from its support till it comes to the orifice C; the extremity of this orifice is covered with leather, or with cloth filled with pitch, so that when the ball is applied to it the passage of the water is effectually prevented. As soon as this orifice is closed, the water raises the ball E which had shut the orifice of the reservoir F; and a portion of it introduces itself into this reservoir, and into the pipe G I H. It thus loses the velocity which it had when the orifice C was shut, and the balls D and E fall down in consequence, the one on its support, and the other on the orifice at E. When this takes place, everything is in the same state in which it was at first. The water begins again to flow through the orifice C; the valve D is again shut; and the same effects are repeated in an interval of time which, for the same ram, undergoes little variation.

As often as the impulse is renewed, a quantity of water is forced up into the reservoir F and the tube H; and as it is prevented from returning by the action of the valve, it must necessarily be delivered at the extremity of H. The use of the air-vessel F is to keep up a continuous motion of the ascending column of water. The communication with the external atmosphere being cut off, the air within F is compressed by a force proportional to the height of the surface of the water in H above its surface in F; and this compressed air acting by its elasticity on the water maintains a continuous flow through H. The air-vessel, however, though it assists the action of the ram, is not an essential part of it; the continuity of the discharge of water may be effected by means of two or more rams, of which the ascensional pipes G I H all terminate in a single branch. On this principle works have been erected at Marly, in France, which raise water in a continuous jet to the height of 57 mètres, or 187 English feet.

As the ascending column of water communicates with the air in the reservoir F, this would soon be exhausted if a fresh portion of air were not introduced at each stroke of the ram. The little tube S, which is stopped by a valve opening inwards, serves for this purpose. At the instant when the orifice C is closed a recoil takes place, by which the water is thrown back from the head of the ram towards the cistern; and a partial vacuum being thus produced within the cylinder *abcd*, the pressure of the external atmosphere forces open the valve in the canal S, and a portion of air enters the cylinder, whence it is driven into the reservoir, excepting the small part of it which lodges in the space between the cylinder *abcd* and the tube E. (Hachette, *Traité des Machines*.)

The invention of the hydraulic ram, at least in the improved form here described, belongs to Montgolfier of Montpellier. A machine, however, on the same principle had previously

M

HYDRAULICS

been suggested, and even erected at Chester, by our countryman, Mr. Whitehurst, but much less perfect in its mode of action; for the orifice *O*, instead of being opened and shut by the action of the water itself, required to be opened and shut by the hand by means of a stop-cock. Owing to this circumstance, Whitehurst's machine was of little utility, and appears to have soon been entirely forgotten.

Hydraulics. That branch of Natural Philosophy which treats of the motions of liquids, the laws by which they are regulated, and the effects which they produce. By some authors, the term *hydrodynamics* is usually applied to the general science of the motion of fluids; while *hydraulics* is more particularly applied to the art of conducting, raising, and confining water, and to the construction of water works. This latter signification appears to be the most consistent with the derivation of the words, though it is hard to draw the line between the two branches of the subject in practice.

There is no part of mechanical science which offers greater difficulties to the mathematician, or where the results of theoretical observation present so little agreement with experience. This arises from the excessively complicated nature of the movements which take place amongst the particles of a liquid mass when its equilibrium has been disturbed, and also partly from the great number of the disturbing causes by which those movements are affected.

The first and principal problem of hydraulics is to determine the velocity with which a liquid flows through an aperture in the bottom, or

Fig. 1.

sides, of a containing vessel. In order to discover the law of this velocity, let ABCD (fig. 1) be a vessel filled with water to the height EF, and let O be a very small opening in the side of the vessel; while the water stands at EF, it will issue from O with a certain velocity depending upon the height of EF above O. Let it, therefore, be proposed to determine to what height GH the vessel must be filled in order that the velocity of efflux through O may be doubled. From the principles of hydrostatics it is shown that the force urging a particle of the fluid at O, through the orifice, is the pressure due to the height of the vertical column above O. Now we may consider, in the first place, that when the velocity of a particle in motion is doubled, the momentum, or moving force, must also be doubled; and, in the second place, if the velocity of efflux is doubled, the number of particles that will be put in motion in the same space of time will also be doubled; and consequently the momentum or moving force also must be doubled on this account. Hence, when the velocity of the discharge through O is doubled, the moving force, which in the present case is the pressure, must be quadrupled. But the pressure is proportional to the height of the fluid above O, hence the height must be quadrupled. By the same process of reasoning, we conclude that to

obtain a threefold velocity, a ninefold depth would be necessary, and so on; and generally that the depths must increase as rapidly as the squares of the velocities; or, in other words, the velocities are proportional to the square roots of the depths of the orifice below the surface of the liquid in the vessel.

By means of this law, the absolute velocity with which water issues from an orifice at any depth under the surface may be ascertained, provided we can determine the velocity for any particular depth. Now, if we suppose the orifice O to be on a level with the surface of the liquid, or if we suppose O to be in the bottom of the vessel covered with an extremely thin film, there would be no pressure on a particle at O, which, therefore, would drop out merely by the effect of its own weight, and consequently with the velocity of a heavy body beginning to fall. But the velocity of a falling body is proportional to the square root of the height from which it has fallen; therefore, since it has been shown that the velocity of discharge through an orifice is proportional also to the square root of the height of the liquid above the orifice, and that the two velocities are the same in one particular case, it follows that they must be the same in all cases; and hence we have this important theorem, 'That the velocity with which a liquid issues from an extremely small orifice in the bottom or side of a vessel that is kept full, is equal to that which a heavy body would acquire by falling from the level of the surface to the level of the orifice.'

Several consequences follow immediately from this fundamental theorem. In the first place, if the aperture be enlarged, each particle of the liquid presenting itself there will escape with the same celerity; and hence the quantity of water that issues through an orifice is as the area of the section multiplied by the square root of the depth. Again, if the water be thrown up in a perpendicular jet, it ought to ascend to the height of the reservoir; or if several orifices be made in the same vessel, each presented upwards, the jets escaping from each of them would all rise to the same height. But by reason of the resistance of the air, the friction on the sides of the orifice, the mutual cohesion of the liquid particles which impedes their separation and escape, and the action of the opposing currents formed in the interior of the liquid, these conclusions must be received with considerable modifications. The effects of the disturbing causes can only be determined by a comparison with experiment.

Water issuing through a hole, or pipe, in the side of a vessel kept full, like other projectiles when the resistance of the air is supposed to be withdrawn, describes a parabola in a vertical plane. Let ABCD (fig. 2) be a cylindrical vessel filled with water, and E an orifice in its side; the water will be projected from E with a velocity that would carry it horizontally through double the space BE in the same time in which a body falls from B to E. But from the instant it escapes at E it begins to

HYDRAULICS

descend with an accelerated motion to the level of D C, while it continues its uniform horizontal flight, and thus describes a parabola meeting the ground in P. Now by the theory of projectiles the velocity of a body moving in a parabola is equal to that which is acquired by a body falling through half the parameter of the diameter, and it has been shown that the

Fig. 2.

velocity at E is equal to $2BE$; therefore the directrix passes through B, and consequently $4BE \times EC = CP^2$. On BC, as a diameter, let there be described a semicircle BLC: then $BE \times EC = EL^2$, and consequently $CP^2 = 4EL^2$, whence $CP = 2EL$. The horizontal range is, therefore, the greatest when the aperture is at F in the middle of BC, and is then equal to CQ, which in its turn is equal to $2FM$, or to the altitude BC. In all other cases there are two apertures E and G equidistant from F which give the same range, for by the nature of the circle there are two equal ordinates, EL and GN.

There is a circumstance connected with the efflux of a liquid through an orifice which requires particular attention. While the liquid is flowing out in this manner, the particles continue to descend in vertical lines till they reach within a short distance of the orifice, as at CD (fig. 3), when those not immediately above it change the

Fig. 3.

direction of their motion, and approach the orifice with very different obliquities, converging as it were to a centre, the position of which is somewhat without the orifice. In consequence of this tendency, the vein of water as it issues out is contracted, its breadth at m, n being less than the width of the orifice. The contraction of jet was first observed by Sir Isaac Newton, who gave it the name of the *vena contracta*, or the contracted vein of the liquid. The distance from the orifice at which the contraction is the greatest depends, in some degree, on the dimensions of the orifice itself; and it is equal to about half the diameter when the orifice is circular and small. The consequence of this contraction is that the discharge of water from a containing vessel is not so great as would be given by theory; but is reduced by the proportion of the breadth of the vein where the contraction is greatest, to that of the orifice. According to Newton this proportion is as 5 to 7 nearly, and according to Bossut as 5 to 8; but these figures would require to be altered according to circumstances that might occur in practice.

As the same quantity of liquid must evidently pass through the orifice and the contracted vein in the same interval of time, it follows that the velocity at the latter point must be greater; and by applying the theorem respecting the velocity of discharge, it is the velocity of the contracted vein that must be regarded.

It is found that if a short tube, about one or two inches long, is inserted in the vessel, and the water be allowed to flow through this tube, the contraction of the vein may be considerably diminished, and the quantity of water discharged through the tube is much greater in the same time than through an orifice of equal diameter. Ventura found that the discharge through a smooth hole in the bottom of a reservoir of tin amounted to 64 quarts in 100 seconds; a short pipe of the same diameter of the hole being applied to the bottom of the reservoir, so as to be flat

Fig. 4.

and even with it, the discharge was augmented to 82 quarts in the same time; and on giving the bottom of the vessel the form here represented, leaving the orifice at A the same as before, the discharge was increased to 92 quarts. By enlarging the lower end of the pipe and giving it a curvature, as B, the quantity of water delivered in the same time received a still further augmentation: such additional pipes are called *adjutages*.

The velocity and other circumstances relative to the motion of water in conduit pipes, and in open canals and rivers, cannot be accurately determined from any abstract theoretical principles; but very numerous experiments have been made on the subject, from which results have been deduced of great value in directing the practice of the engineer. When water flows from a reservoir in horizontal pipes of the same diameter, the discharges made in equal times are nearly in the inverse ratio of the square roots of the lengths. But this rule applies within limits that are not very extended, and is not admissible with respect to long pipes; and, according to M. Darcy, it requires to be modified according to the nature and the state of the pipe. It was found by Bossut that water has its velocity diminished eight times in passing through a tube of one inch in diameter and 204 feet long. In order to obtain the greatest discharge from a pipe, it is necessary that the inside should be smooth, the width uniform, and sudden changes of direction be avoided. The want of evenness of surface impedes the motion of the fluid, which is further obstructed by any sudden changes in the direction, or the rate of flow. Whether the pipe or channel be contracted or enlarged, the change is always attended with a proportionate loss of velocity. Any sharp flexure of the pipe or conduit will occasion a still greater waste of the moving force. It has been found that a curvilinear pipe discharged less water than a rectilinear one of the same length; and that when the flexures are vertical the quantity is less than when they are horizontal. When a large pipe has a number of contrary flexures, the air sometimes mixes with the water and occupies the highest parts of those flexures, which means the velocity of the fluid is greatly retarded, and the quantity discharged greatly diminished. The ancient Romans appear to have

HYDRAULICS

been aware of this fact, as they provided escapes for the air that might be brought down in their aqueduct bridges of Lyons and elsewhere.

When liquids flow through very small orifices, or capillary tubes, the resistance is greatly augmented, and the rules that apply to orifices or pipes of considerable diameter no longer hold good. In this case the velocity depends very considerably on the temperature of the fluid. Thus pure water at a temperature near the boiling point, is found to flow through a capillary tube five times faster than when the temperature is near the freezing point. Alcohol, is found to flow six times faster than before, when the temperature is raised to 124°. Quicksilver is less affected, but it is found to endure heat through a wider range.

With respect to water running in open channels or in rivers, the resisting forces are so numerous, and of so irregular a nature, that it is difficult to attempt to deduce their effects from any general principles. In all cases the velocity is increased by the depth of the stream, and of the declivity over which it runs up to a certain limit, i.e. till the resistance, which increases with the velocity, becomes equal to the acceleration, when the motion of the stream becomes uniform. The resistance, of course, depends a great deal upon the evenness of the bottom and sides of the channel, which has lately been ascertained by the researches of Bazin to be a very important element in the calculations of the yield of such a mode of conveying water. The greatest velocity of a river is at the surface and in the middle of the stream, from which it diminishes towards the sides and bottom, where it is the least. It has been found by experiment that if from the square root of the velocity at the surface in the middle of the stream, expressed in inches per second, unity be subtracted, the square of the remainder will be the velocity per second of the water at the bottom. Thus let v = the velocity at the surface in the middle of the stream, then the bottom velocity will be expressed by

$$1)^2 = v - \sqrt{2v+1}.$$

It has also been found, by experiment, that the mean velocity (or that with which, were the whole stream to move, the discharge would be the same as the real discharge) is equal to half the sum of the greater and less velocities, as computed by the above formula. The mean velocity is therefore

$$\frac{v + (\sqrt{v-1})^2}{2}.$$

These formulæ are deduced from the experiments of Du Buat. (Playfair's *Elements of Natural Philosophy*.)

When the sections of a river vary, the quantity of water remaining the same, the mean velocities are inversely as the areas of the sections; but when the river receives a permanent addition, the velocity is immediately increased. The effect of this is to augment the action on the sides and bottom, in conse-

quence of which the width is augmented, and sometimes, though more rarely, the depth. This increase of width, by multiplying the points of resistance, again reduces the velocity till an equilibrium is established between the velocity and resistance; after which the bed of the river becomes as nearly permanent as the conditions of the flow of water will allow it to be. [RIVER.]

The determination of the force with which a liquid in motion strikes a solid at rest, and the force necessary to propel a solid immersed in a liquid, is another important branch of the science of Hydraulics, though the name will hardly apply to it. Of the general principles hitherto deduced from theory, there are, however, only a few which afford a tolerable approximation to the results of experiment. The force of a stream must be regarded as compounded of the force of each particle, and of the number of particles that strike the object in a given time. Now, the force of each particle is proportional to the velocity with which it impinges; and the number of particles that strike in a given time is also proportional to the velocity of the stream, supposing its section to remain the same; hence the whole force of the stream is as the square of the velocity. It follows that if the plane struck by the stream be itself in motion, the impulse will be as the square of the differences of their velocities; and if a stream strike obliquely upon a plane, its force is less than if it struck directly in the same plane in the ratio of the cube of the sine of obliquity to the cube of the radius. But it would appear from experiment that this last consequence only holds true when the angle of inclination is greater than 60°. It might seem (and it is agreeable to theory to suppose) that a plane moving against a liquid at rest with a certain velocity, would receive the same impulse as if the liquid were to move with that velocity, and the plane to remain at rest. This, however, is not confirmed by experience, which proves that the resistance of a liquid to a body in motion is considerably less than the percussion of the liquid moving with the same velocity against the body at rest. The difference arises from the action of the liquid on the hinder part of the moving body, by which the resistance is in some degree counteracted; but the resistance depends very materially on the figure of the body, and the relation of its length to its breadth. A conical-shaped body, when its length is considerable, is more easily drawn through the water with its broad than with its narrow end forwards. In general it is found that whatever tends to diminish the adhesion of the body to the liquid, tends also to diminish the resistance. A wedge, which has its sides rubbed with grease, is found to move more freely through the water than if it were presented in its natural state; hence the great advantage of coating a ship's bottom with copper. [RESISTANCE.]

The following are some of the best works on the subject: Belidor, *Architecture Hy-*

HYDRIDES

draulique; Frisi, *Opera Omnia*; Bossut, *Traité d'Hydrodynamique*; Du Buat, *Principes d'Hydraulique*; Prouy, *Nouvelle Architecture Hydraulique*; *Récherches Physico-Mathématiques sur la Théorie des Eaux Courantes*; Navier, *Résumé des Leçons données à l'École Polytechnique*; *Raccolta dei Autori Italiani che hanno trattato sur l'Acque Corrente*; D'Aubrisson's *Traité d'Hydraulique*; Eytelwein, *Handbuch der Mechanik*; Leslie; Young; Robison; Lardner's *Treatises on Hydraulics*; Nicholson's translation of Venturi's *Tracts*; &c. &c. A more complete list of the bibliography on this subject will be found in the tract upon Hydraulic Engineering in Weale's Series, by G. R. Burnell.

Hydrides. Compounds of hydrogen with other elements or radicals.

Hydriodic Acid. A gaseous compound of hydrogen and iodine, obtained by the mutual decomposition of iodide of phosphorus and water. It is composed of 126 iodine + 1 hydrogen; and its equivalent, therefore, is 127. The specific gravity of this gas is 4.4. It is rapidly absorbed by water, furnishing a sour dense liquid, which becomes brown by exposure to air, in consequence of the evolution of a little iodine. It is decomposed by chlorine, which abstracts the hydrogen to form hydrochloric acid, and sets the iodine free.

Hydrobromic Acid. A gaseous acid composed of 78 bromine + 1 hydrogen. It is obtained by the mutual decomposition of bromide of phosphorus and water.

Hydrocarbons. Compounds of carbon and hydrogen. These combinations are numerous, and form a variety of important gaseous, liquid, and solid products, the composition and characters of which are stated under other heads. Marsh gas and olefiant gas may be cited as instances of gaseous, oil of turpentine and benzole of *liquid*, and naphthaline and paraffin of *solid* hydrocarbons.

Hydrocardia. Dropsy of the pericardium.

Hydrocele (Gr. ὕδωρ, and κήλη, *a tumour*). A collection of watery or serous fluid in the tunica vaginalis testis.

Hydrocephalus (Gr. ὕδωρ, and κεφαλή, *the head*). Dropsy of the brain, or water in the head. The acute form of this disease is almost confined to childhood; it is marked by febrile symptoms, pain of the head, and in very young children enlargement of it. The eyes are irregularly directed and the pupil dilated. The eyes are not perfectly closed in sleep, and there appears a degree of delirium, as far as can be judged of in children; coma, convulsions, and paralysis are frequent consequences. The ventricles of the brain are the chief seat of the watery accumulation. Bleeding from the temporal artery or jugular vein, cold applications to the head, and brisk purgatives with calomel, are the leading remedies.

Hydrocharidaceæ (Hydrocharis, one of the genera). A natural order of floating Endogens of the Hydral alliance, inhabiting Europe and some other places, known by their

HYDRODYNAMICS

tripetaloidous flowers with an inferior ovary. They agree with *Alismaceæ* in habit and in want of albumen, but differ in their carpels being definite in number. They are not of any known use, but many of the species are handsome when in flower.

Hydrochloric Acid (Gr. ὕδωρ, and χλωρός, *pale*). A gaseous compound of 1 atom of chlorine = 36, and 1 atom of hydrogen = 1; the equivalent, therefore, of the hydrochloric acid is = 37. [MURIATIC ACID.]

Hydrocorisæ (Gr. ὕδωρ, and κορίς, *a bug*). The name of a tribe of Hemipterans, including the water-bugs; these differ from the *Grocorisæ*, or land-bugs, in having minute antennæ inserted beneath the eyes. This tribe includes the water-scorpions (*Nepidae*) and the boat-men (*Notonectidæ*).

Hydrocotyle (Gr. ὕδωρ, and κοτύλη, *a cavity*). A curious little native Umbellifer, sometimes called Pennywort, remarkable for its round peltate leaves. It is reputed to be injurious to sheep, but probably without just cause, the marshy situations in which it grows being far more inimical to these animals.

Hydrocyanic Acid (Gr. ὕδωρ, and κύανος, *blue*). This noxious compound was first discovered by Scheele in 1782, and was called *Prussic acid*, but its real nature was not understood till the discovery of cyanogen by Gay Lussac in 1816. Its ultimate components are 2 atoms of carbon, 1 of nitrogen, and 1 of hydrogen. It is obtained by gently heating in a small retort a mixture of 3 parts of cyanide of mercury and 2 of hydrochloric acid. The evolved vapours should be passed through a tube containing fragments of marble, in order to absorb any hydrochloric acid that may chance to distil over, and ultimately condensed in a receiver immersed in a freezing mixture. The hydrocyanic acid is a colourless liquid, having a strong odour resembling that of bitter almonds; its specific gravity at 45° is 0.7. It boils at 80°, and freezes at 0°. Dissolved in a large quantity of water, it imparts to it the smell and taste of the laurel or bitter almond water; it is intensely poisonous—less than a grain of it has destroyed the life of an adult in twenty minutes. Largely diluted with water it is used in medicine as a sedative, and externally in chronic skin diseases. The dilute hydrocyanic acid of the London *Pharmacopœia* contains 2 per cent. of the real acid, and that sold under the name of Scheele's acid contains about 5 per cent. Of this, if not further diluted, from twenty to thirty drops would generally suffice to destroy the life of an adult. The antidotes to be used in cases of poisoning by this acid are chlorine, ammonia, cold affusion, and artificial respiration. (Taylor *On Poisons*.)

Hydrodynamics (Gr. ὕδωρ, and δύναμις, *power*). The science that applies the principles of dynamics to determine the conditions of motion, or rest, upon fluid bodies. It is usually divided into two branches; namely, *hydrostatics*, which explains the laws of the

HYDRODYNAMICS

equilibrium, pressure, and cohesion of fluids; and *hydraulics*, which explains the laws of their motion, together with the principles of the machines in which they are chiefly concerned. Though the term *hydrodynamics* is sometimes applied generally to fluids of all kinds, it is more usually confined to the non-elastic or incompressible fluids, such as water, mercury, &c.; in which case the science which treats of the equilibrium of the compressible and elastic fluids, like the air, is called *aërostatics*, and that which treats of their motion is called *pneumatics*.

Hydrodynamics, though a science of immense importance in its application to the various purposes of life, was not cultivated to any extent by the ancients, all their knowledge of the doctrine of fluids being limited to a few propositions regarding the pressure and equilibrium of water. Archimedes, indeed, established the general principles which serve as the foundations of hydrostatics in his treatise *De Insidentibus Humido* (*περὶ τῶν ὑδατῶν ἐπιστάμενον*); and Ctesibius and Hero, who flourished at Alexandria about 120 years after Christ, invented the pump of compression, the siphon and the forcing pump, unless the siphon is to be considered a much more ancient invention, for the Egyptian hieroglyphics contain very correct representations of this instrument, and the Roman aqueducts of about 70 B.C. display the knowledge of the ancients in this matter. Julius Frontinus, who was inspector of the public fountains at Rome, in the time of Nerva and Trajan, wrote a work on the Roman aqueducts, and on the modes of distributing water then in use; but he appears to have been unacquainted with the law of the velocities of running waters depending on their depth. The first known modern treatise on Hydrodynamics was published, in 1639, by Castelli, a disciple of Galileo, under the title of *Della Misura dell' Acque Correnti*; and it contains a satisfactory explanation of various phenomena in the motion of fluids. Torricelli discovered the important property that the velocities of fluids, issuing through an orifice, is as the square roots of the pressure; Mariotte, in his *Traité du Mouvement des Eaux*, employed the principle of Torricelli, and explained the discrepancy between theory and observation by ascribing it to the retardation of the water's velocity arising from friction. Guglielmini was the first who treated of the motion of water in rivers and open channels. The subject of the oscillation of waves, one of the most difficult in the whole science, was first investigated by Sir Isaac Newton, who determined the duration of the oscillations, and thence concluded that the velocities of waves formed on the surface of water are in the subduplicate ratio of their size. He was also the first who observed the contraction in the vein of a fluid issuing through an orifice, and he regarded the contracted section as the true orifice, by which the theory of the escape of water was rendered more conformable to experience. The

Hydrodynamica of Daniel Bernoulli was published in 1738. His theory of the motion of fluids consists in supposing, firstly, that the surface of a fluid in a vessel, while emptying itself by an orifice, remains unchanged, and always horizontal; and, secondly, that if the fluid may be conceived to be divided into an infinite number of horizontal strata, all the strata remain parallel, and descend vertically, with velocities inversely proportional to their breadth, or to the horizontal sections of their reservoirs. From these suppositions, and by means of the application of the principle of the conservation of living forces, he obtained solutions of the principal problems of hydrodynamics. The mathematical theory of the nature of fluids was further investigated by John Bernoulli, Maclaurin, and the celebrated D'Alembert, the latter of whom placed it in an entirely new light by the application of Euler's doctrine of partial differences. One of the best treatises on hydrodynamics which we possess, is that of the Abbé Bossut, in which are given the results of a very extensive set of experiments, performed with great judgment and accuracy. Similar and more extensively varied experiments were afterwards undertaken by Du Buat, whose *Principes d'Hydraulique*, in three volumes, contains a theory founded upon the results thus obtained. Du Buat was the first who ascertained the effect of heat in increasing the fluidity of bodies he experimented upon. Among the other researches more recently undertaken for the purpose of throwing light upon this difficult and interesting subject, we may mention those of Procy, Coulomb, Eytelwein of Berlin, Bidoni of Turin, Sabatier, Poncelet, Lesbros, Morin, George Bennie, Jardine of Edinburgh, Darcy, Belanger, Bazin, &c. From the four last-named authors, some valuable results with respect to the flow of water in pipes may be derived; Poncelet, Lesbros, and Morin principally turned their attention to the effect of various orifices upon the rate of discharge of water in channels.

The analytical theory of hydrodynamics resolves itself into the integration of equations of practical differences, a branch of the calculus which we owe to Euler, who gave the general formulæ for the motion of fluids, founded on the laws of their equilibrium, and thus reduced the whole question of the mechanics of fluid bodies to a simple one of analysis. If these formulæ could be integrated, we should be able to determine completely, in every case, all the circumstances of the motion and action of a fluid subjected to the influences of any forces whatever; but such is the difficulty of the subject, that the integration, except in a few limited cases, has hitherto resisted the efforts of the greatest mathematicians. Lagrange, in his *Mécanique Analytique*, had deduced the analytical formulæ of the motion of fluids from the principle of vertical velocities, and thus shown that dynamics and hydrodynamics are only branches

HYDROFLUORIC ACID

of one great principle, and results, as it were, of a single general formula. Laplace, in his *Mécanique Céleste*, has also given the general equations of hydrodynamics, and applied them to the questions of the figure of the earth, and of the tides. Since the days of those illustrious mathematicians, the theory has been illustrated, with reference to application to particular cases, by Poisson, Cauchy, Navier, Challis, Belanger, Weisbach, and others; but it cannot be said to have received any particular extension. Treatises on Hydrodynamics are very numerous. Besides the works of Lagrange and Laplace, and the others mentioned, we would refer the student to Bossut's *Hydrodynamique*; Poisson's *Mécanique*; Moseley's *Elementary Treatise on Hydrostatics and Hydrodynamics*; Jamieson's *Mechanics of Fluids*, &c. [HYDROSTATICS and HYDRAULICS.]

Hydrofluoric Acid. A highly corrosive and very volatile liquid, obtained by distilling in leaden or silver vessels a mixture of 1 part of pure fluor spar in fine powder with 2 of sulphuric acid. This compound acts vehemently upon glass and all silicious combinations; it is a compound of 19 fluorine + 1 hydrogen = 20 hydrofluoric acid.

Hydrogen (Gr. *ὕδρω*, and *γεννᾶν*, I generate). This important element is only known to us in the gaseous or permanently elastic form. It was formerly called *inflammable air*, and was sometimes considered as identical with *phlogiston*, or the matter of heat. It is usually procured by the action of sulphuric acid and zinc or iron upon water, or by passing the vapour of water over red-hot iron. Pure hydrogen is a colourless, tasteless, and inodorous gas. 100 cubic inches at mean temperature and pressure weigh 2.13 grains; so that its specific gravity compared with air is as 67 to 1,000, and it is exactly 16 times lighter than oxygen. It is therefore the lightest known form of matter, being 14.4 times lighter than air, and 11,000 times lighter than water. It burns in contact with air with a pale flame; and when mixed with three or four times its volume of air, or with half its volume of pure oxygen, and inflamed, it burns rapidly, and in the latter case with violent explosion. The only product of this combustion is *water*, which is thus shown to consist of 1 part by weight of hydrogen with 8 of oxygen; so that upon this datum the number 8 becomes the equivalent of oxygen, and 9 that of water. Hydrogen is not absorbed by water, and animals soon die when confined in it.

Hydrography (Gr. *ὕδρω*, and *γραφῶν*, I write). The description of the waters which exist at the surface of the earth, particularly with reference to the bearings of the coasts, the depths, currents, and other circumstances required to be known for the purposes of navigation. This term implies the same thing with regard to the sea that geography implies with regard to the land. *Hydrographical charts or maps* are projections of some part of the ocean, in which the meridians, parallels, &c., with

HYDROLOGY

the coasts, capes, rocks, shallows, &c., are laid down for the uses of navigation.

Hydrogurets or Hydrurets. Compounds of hydrogen with metals, &c. The term *hydride* is sometimes similarly used.

Hydroleases (Hydrolea, one of the genera). A small group of Monopetalous Exogens, now included in *Hydrophyllaceae*.

Hydrolite (Gr. *ὕδρω*, water; *λίθος*, a stone). A name given to Gmelinite (Soda Chabazite), as containing a large quantity of water. It is a silicate of alumina, iron, and potash, containing nearly twenty per cent. of water, and has been found in the amygdaloidal rocks of Antrim in Ireland.

Hydrology (Gr. *ὕδρω*, and *λόγος*). The part of the general science of Physical Geography that relates to the phenomena of water in the liquid form.

The principal part of the water on the globe occupies a large depression of the surface, and is denominated the OCEAN. Different parts of it are known as the PACIFIC, the ATLANTIC, the INDIAN, the ARCTIC, and the ANTARCTIC Oceans. The rest of the surface rises above the level of the ocean, or if depressed is occupied by waters that do not connect with the great body of the ocean.

The form of the land, or in other words the form of the line of intersection of the surface of the ocean with the land, is extremely irregular, the water entering the land at numerous recesses and the land projecting into the water by various promontories. The former are called INLAND SEAS, GULFS, or BAYS, according to the extent to which the water is land-locked. The waters reposing in hollows within the land are called LAKES, and the waters running along the surface to enter the ocean or the lakes or be lost in plains are called RIVERS. The rivers connect with each other, and form large and definite RIVER SYSTEMS, draining definite tracts of land.

The grand phenomena of the ocean include the regular TIDES and CURRENTS which affect it, the WINDS and STORMS which disturb it; its temperature, depth, and mineral contents. The phenomena of fresh water actually on the surface are quite distinct; and the phenomena of water in the atmosphere, including the falling and distribution of rain, belong to METEOROLOGY, another department of Physical Geography.

Few things connected with the laws of matter and their visible results on the earth are more striking than those which belong to the circulation of water around and through the earth. The warm air that floats above the surface of the ocean is constantly raising vapour, with which the atmosphere is charged to the extent of at least four parts out of five, being ready to give it off at the slightest change of temperature. When the air in this state impinges upon land, it becomes either more heated and therefore more absorbent (the additional supply being readily obtained), or chilled and less absorbent, and in a condition

HYDROMANCY

to deposit moisture as rain. Thus on all high grounds, which are necessarily colder than the lowlands in the same latitude, and on all cooler latitudes to which clouds are drifted, there is occasional rain, often very heavy and continuous over large tracts. The rain that thus falls is partly, no doubt, reabsorbed into the air, or is used in the production of vegetable and animal tissue. A great part, however, runs along the earth's surface in streams and rivers, circulating at the surface visibly, and the rest enters the strata, pervades them, and passes through them invisibly from place to place, coming out again in springs, and completing another circulation out of sight.

The influence of water is felt everywhere, and all the phenomena of structure observable in rocks of every kind are influenced by this complete and never-ceasing circulation.

Hydrology is thus a department of great importance and interest. The details will be found considered in various separate articles, of which the names are printed in the above paragraphs in capital letters.

Hydromancy (Gr. *ὕδμαντις*, a water-prophet). Among the ancients, a method of divination by water. It was performed in various ways. Its origin is ascribed by Varro to the Persians.

Hydromel (Gr. *ὕδωρ*, and *μέλι*, honey). Water sweetened with honey, which when fermented forms *mead*.

Hydrometer (Gr. *ὕδωρ*, and *μέτρον*, measure). An instrument for determining the specific gravities of liquids, and thence also the strengths of spirituous liquors. Various instruments of different forms have been proposed for ascertaining readily the specific gravities of fluids; but Sikes's hydrometer, directed by Act of Parliament to be used in collecting the revenue of the United Kingdom, may be considered as deserving of description. This instrument is represented in the annexed figure. A B is a flat stem, divided on both sides into eleven equal parts, each of which is again subdivided into two. The stem carries a hollow brass ball B C, in which is fixed a conical stalk C D, terminating in a pear-shaped bulb D. Eight different weights of a circular form, and marked with the numbers 10, 20, 30, 40, 50, 60, 70, and 80, are cut in the manner represented at W, so that they can be placed on the stalk C D. When the strength of spirits is to be measured, one of the circular weights is placed

on C D, which is found by trial to be capable of sinking the ball so far that the surface of the liquid cuts the stem at one of the divisions between A and B. The number of this division is then observed, and also the temperature of the liquid; and the corresponding strength per cent. of the spirit is then found in a table which accompanies the instrument. Glass hydrometers, adapted to various scales, are in con-

HYDROMETER

stant use for determining the specific gravities of all kinds of liquids.

Jones's Hydrometer is an improvement on Sikes's. It has a square stem carrying a different scale upon each of its four sides, and is accompanied by three separate weights, which with the unweighted instrument correspond with the four scales.

Baumé's Hydrometer is much used on the Continent. In principle it does not differ from Sikes's. Its scale, however, is quite arbitrary; and as the gravities of liquids are frequently given in degrees Baumé in foreign books, the following tables will be found useful in translating these degrees into real specific gravities:

Table for the Reduction of Degrees of Baumé's Hydrometer to real Specific Gravities (water = 1). Liquids heavier than Water.

Degrees Baumé	Specific Gravities	Degrees Baumé	Specific Gravities	Degrees Baumé	Specific Gravities	Degrees Baumé	Specific Gravities
0	1.000	20	1.152	39	1.345	58	1.617
1	1.007	21	1.160	40	1.357	59	1.634
2	1.013	22	1.169	41	1.369	60	1.652

Twaddell's Hydrometer is much used by English chemical manufacturers for testing liquids heavier than water. Its degrees are converted into ordinary specific gravities by multiplying them by 5, adding 1000, and dividing the sum by 1000. Thus

$$20^{\circ} \text{ Twaddell} = \frac{20 \times 5 + 1000}{1000} = 1.100.$$

HYDROMETRA

Another easy method of determining the densities of different liquids, sometimes practised, is by means of a set of glass beads previously adjusted and numbered. Thrown into any liquid, the heavier balls sink and the lighter float at the surface; but one of them approaching the density of the liquid will be in a state of indifference as to buoyancy, or will float under the surface. The number on this ball indicates, in thousandths parts, the specific density of the liquid.

Hydrometra (Gr. ὕδωρ, and μέτρα, the womb). Dropsy of the uterus.

Hydrometridæ (Gr. ὕδωρ, and μέτρα). A family of *Geocorise*, or land-bugs, but of aquatic habits; not, however, living in water, but frequenting the surface.

Hydropathy (Gr. ὕδωρ, and πάθος, disease). This term is applied to a treatment of disease generally called the *cold-water cure*; it was suggested, in 1828, by Vincent Priessnitz of Graefenberg in Silesia, and consists in the internal and external administration of cold water, accompanied by air and exercise, early hours, and strict attention to diet; there are, therefore, many cases in which such a plan rationally pursued must be obviously useful, more especially to overphysicked individuals, residing in populous towns, eating and drinking too much, and keeping bad hours. At the same time, some parts of the treatment are by some considered to be 'of so outrageous a character as frequently to aggravate the disease which they are intended to cure, and occasionally to endanger the life of the patient.'

Hydropericardium (Gr. ὕδωρ, and περι-καρδιον, about the heart). Dropsy of, or an unnatural accumulation of watery fluid in, the sac of the heart.

Hydrophane (Gr. ὕδωρ, and φαίνω, I show). A variety of opal, which is white and opaque when dry, but becomes translucent in water.

Hydrophides (Gr. ὕδωρ, and ὄφις, a serpent). A name applied to the section of *Ophiidians*, including the water-snakes. These are principally distinguished by having the tail compressed or flattened sideways, for the purpose of swimming. They are armed with poison fangs; but these are of small size, and are associated with a row of non-venomous maxillary teeth.

Hydrophilidæ (Gr. ὕδωρ, and φίλος, I love). A family of Pentamerous Coleopterans, including those species which have short clavate antennæ, long and slender palpi, mandibles bidentate at the tips; body oval and convex; and the hind-legs often ciliated. The *Hydrophilidæ*, like the *Dytiscidæ*, are aquatic beetles, and have wings by which they can transport themselves from one piece of water to another; but they are vegetable-feeders, and are less active in their movements than the predatory water-beetles. The family includes many genera. The typical species, *Hydrophilus caraboides*, is common in the stagnant ponds and ditches of this country.

Hydrophobia (Gr. ὑδροφοβία, dread of

HYDROPHYTES

water). A disease remarkably characterised by alarm at the approach of water, and caused by the bite of a mad dog or other rabid animal; but it does not appear capable of being communicated by the human subject. At some indefinite period after the bite, and often long after all local injury has healed, itching and pain in the bitten part, heaviness, great restlessness and uneasiness, and mental alarm ensue, followed by pains about the neck, sense of choking, and great irritability and horror at any attempt to drink, although solid food can generally be swallowed. Fever, vomiting, excessive thirst, spitting of viscid saliva, and difficult respiration then come on, with irregular pulse and convulsions, under which the sufferer sinks more or less rapidly according to the strength of his constitution. Delirium sometimes precedes death, but not always; in many instances the judgment appears unaffected. It unfortunately happens that nothing in the way of cure, and little even as palliation, had been successfully effected in this disease; but there appears little doubt that the timely application of preventive measures has been successful, and of these the amputation or excision of the bitten part, and the application of caustics to it, or both united, are most to be relied on; and the sooner they are resorted to the better the chance of success, but it appears that they may be effective any time before the appearance of symptoms. Among caustics, the nitric acid is perhaps the most effective. It energetically acts upon and decomposes all animal matter, and fluids more especially; and if applied very soon after the bite, can scarcely fail to be effective: it also penetrates the wound, and forms a sloughing sore. The appearance of madness in dogs, in its early stages at least, is unfortunately not very well defined, nor always easily distinguishable from their other maladies: whether the bite is less dangerous before they become evidently rabid than afterwards, seems to be doubtful. In general the animal is observed to be unusually dull and unsocial, refuses food, hangs his head, and appears drowsy: he flies at strangers, but usually recognises his master, though with comparative indifference. Afterwards his breathing is quick and heavy; frothy matter runs from his mouth; he walks slowly, but occasionally runs and starts forward; at length he forgets his master, often falls down, flies at everybody in his way, grows furious, and in four-and-twenty or thirty hours dies.

Hydrophyllaceæ (Hydrophyllum, one of the genera). A natural order of herbaceous Exogens, inhabiting America and belonging to the Cortusial alliance. They come very near to *Boraginaceæ*, from which they are known by their one-celled, many-seeded fruit, and other characters. Some *Polemoniaceæ* have the habit of this order. The species of *Eutoca* and *Phacelia* are often cultivated on account of their pretty flowers.

Hydrophytes (Gr. ὕδωρ, and φυτόν, a plant). Plants which thrive in water; as

HYDROPS

given by botanists to algaecious plants, and sometimes confined to those which are found in fresh water. It has been remarked by Lyell (*Principles of Geology*) that the number of hydrophytes is very considerable, and their stations more varied than could have been anticipated; for while some plants are daily covered and uncovered by the tide, others live in abysses of the ocean at the extraordinary depth of 1,000 feet; and although such situations must be profoundly dark, at least to our organs, many of these vegetables are highly coloured.

Hydrops (Gr. ὕδρωψ). Dropsy. An unnatural accumulation of fluid in the cellular membrane or cavities of the body.

Hydrophthalmia (Gr. ὕδωρ, and ὀφθαλμος, the eye). Dropsy of the eye.

Hydrorachitis (Gr. ὕδωρ, and ῥαχίς, the spine). A tumour upon the spine of infants; at first of a blue colour, but afterwards becoming translucent; it is attended with paralysis of the lower limbs, and is usually fatal in its consequences.

Hydroscope (Gr. ὑδροσκόπιον, from ὕδωρ, and σκοπέω, I view). An instrument anciently used for measuring time by means of the flowing of water through a small orifice. It consisted of a cylindrical tube, conical at the bottom. The cylinder was graduated; and as the water trickled out at the apex of the cone, its surface became successively contiguous to the divisions marked on the cone, and thereby pointed out the hour.

Hydrostatic Balance (Gr. ὑδροστάτης). A balance for weighing substances in water, for the purpose of ascertaining their specific gravities.

Hydrostatic Bellows. An apparatus for illustrating the *hydrostatic paradox*, or that peculiar property of liquids in virtue of which they transmit pressure equally in every direction.

In the annexed figure B C and D E are two flat boards united by leather or flexible cloth A, water-tight. A short tube fitted with a stop-cock communicates with the interior of the bellows, by which the liquid may be discharged. From the short tube a long tube T rises perpendicularly, and terminates in a funnel F. The upper board B C is loaded with weights, which press it against the lower board D E. On pouring water into the funnel F it will descend through the tube T, and enter between the boards; and by continuing the supply a column will be formed in the tube, the weight of which, transmitted through the water in the bellows, will raise and support the weights on the board.

Hydrostatic Paradox. A term frequently employed to designate that principle in hydrostatics according to which any quantity of water, however small, may be made to balance

HYDROSTATICS

any weight, however great. [**HYDROSTATIC BELLOWS.**]

Hydrostatic Press, also called the **Hydraulic Press**, and sometimes, from the name of the engineer who gave it the form under which it is now constructed, and brought it into general use, **Bramah's Press**. A machine by means of which an enormous force or pressure is obtained through the medium of water. The principle is the same as that of the *hydrostatic bellows*; from which, indeed, it only differs by the substitution of a strong forcing pump for the long tube, and a barrel and piston for the leather and boards. It consists of a short and very strong pump-barrel A B, with a solid piston C

of proportionate strength, which is pushed upwards against the thing to be compressed by water driven into the barrel beneath it at F from the small forcing pump E. If the small pump have only one-thousandth of the area of the large barrel, and if a man by means of its lever handle D press its piston down with a force of 500 pounds, the piston of the great barrel, in virtue of the hydrostatic principle of equal pressure in all directions, will rise with a force of a thousand times 500 pounds, or more than 200 tons. The hydrostatic press is applied to a great variety of useful purposes; for compressing bales of goods, as paper, cotton, wool, tobacco, &c.; for expressing oils from seeds, raising weights, uprooting trees, &c.

Hydrostatics. The name of an order of *Acatephes*, including those which have one or more air-vessels appended to their body.

Hydrostatics. The science which explains the properties of the equilibrium and pressure of liquids. It is the application of statics to the peculiar constitution of water or other bodies existing in the perfectly liquid form.

The whole doctrine of the equilibrium and pressure of liquids is deduced from the following fundamental law: 'When a liquid mass is in equilibrium under the action of forces of any kind, every molecule of the mass sustains an equal pressure in all directions.'

One of the most obvious consequences of the above law is, that the surface of a liquid when at rest in an open vessel, and acted upon by no other force than gravity, is horizontal, or perpendicular to the direction of gravity. If the directions of gravity are parallel, the surface will consequently be a plane; if they converge to a point, the surface of the liquid will be a portion of a sphere. Stagnant water at the surface of the earth, therefore, assumes the spherical figure; but by reason of the magnitude of the sphere the curvature of any small portion of it is insensible, and the surface may be regarded as a plane. A ring surrounding the earth would bend away from a perfectly straight line only eight inches in a mile.

If a free communication is made between two or more vessels containing a liquid by

HYDROSTATICS

or otherwise, the surface of the liquid when in equilibrium will always stand at the same level.

The liquid contained in a vessel being at rest, and subjected to the action of gravity only, any particle of it is pressed in all directions (vertically, horizontally, or obliquely) by a force which is equal to the weight of the vertical column of the liquid incumbent on it.

Instead of a particle of the liquid itself, we may consider the column to rest on an indefinitely small portion of the bottom or the sides of the vessel in which it is contained, and it will follow that the pressure on an indefinitely small portion of the area at any point of the bottom or sides is perpendicular to the plane of that area, and equal to the weight of a vertical column of the liquid standing on it as a base and reaching to the surface. Hence the whole pressure sustained by any finite portion of the bottom or sides of the vessel is equal to the weight of a column of the liquid having for its base the surface pressed on (extended into a plane if necessary), and for its altitude the distance of the centre of gravity of that surface from the surface of the liquid.

The point of a plane surface at which the resultant of all the liquid pressures upon it is applied, is called the *centre of pressure*. From the above it follows that the pressure on the bottom of the vessel depends only on the magnitude of the bottom and the depth of the liquid, and is entirely independent of the form of the sides and of the quantity of liquid in the vessel. It is on this principle that the *hydrostatic press* and *hydrostatic bellows* are constructed. - A body immersed in a liquid is pressed upwards by a force equal to the weight of the liquid it displaces; and the difference between the absolute weight of a body and its weight when entirely immersed, is the same with the weight of a quantity of the liquid equal in bulk to the body. The *specific gravity* of a body, therefore, being the ratio of its own weight to that of an equal volume of water, may at once be found by weighing it first in air and then in water. The equilibrium of solid bodies floating on liquids, a subject discussed by Archimedes in his treatise *De Humido Insidentibus*, is an important part of hydrostatics in consequence of its relation to the construction and stowage of ships. A body placed on a fluid specifically heavier than itself, will sink so far that the weight of the fluid displaced is equal to the whole weight of the body; and when it assumes the position of equilibrium, the line which joins the centre of gravity of the body and the *centre of buoyancy* (which is the same as the centre of gravity of the immersed part supposed to be homogeneous) is perpendicular to the surface of the water, or the horizon.

The centre of gravity of a body is a fixed point relatively to the body itself; but the centre of buoyancy, which depends on the figure of the immersed part, will change its place when the figure or relative situation of the im-

HYGROMETER

mersed part undergoes any alteration. The character of the equilibrium of a floating body depends upon the relative positions of the centres of gravity and buoyancy with respect to a certain point called the *metacentre*, which latter may be defined as the point in which the line joining the centre of gravity with the centre of buoyancy, in the position of equilibrium, is intersected by the vertical through the centre of buoyancy corresponding to a slightly altered position of the body. The metacentre may in all cases be determined from the form and density of the body, and the equilibrium will be stable, neutral, or unstable, as it falls above, upon, or below the centre of gravity.

Hydrosulphates or Hydr. alph.

Compounds of hydrosulphuric acid or sulphuretted hydrogen.

Hydrosulphuric Acid. [SULPHURETTED HYDROGEN.] This compound has also been called *hydrothionic acid* (from hydrogen, and Gr. *θειον, sulphur*).

Hydrothorax (Gr. *θώραξ*, and *θώραξ, the chest*). Dropsy of the chest. The symptoms are: difficult breathing when in a recumbent posture, paleness, cough, thirst, swelling of the legs and feet, quick and often irregular or intermitting pulse. [DROPSY.]

Hydrotæa (Gr. *ὕδρως*; *water, animal*). These are defined by the best zoologists as gelatinous, oblong, or conical animals with a contractile body, an intestinal cavity, and an oral aperture, which is surrounded by a circlet of arms or tentacles.

Hydruet or Hydrogæret. A term applied in Chemistry to some of the compounds of hydrogen, more especially with the metals.

Hydrus (Gr. *ὕδρως*). A genus of water snakes, characterised by a compressed or laterally flattened tail adapted for swimming; and by having many maxillary teeth, like non-venomous serpents, but with the first, larger than the rest, and grooved for the transmission of a poison-duct. The species are confined to the seas of the warmer latitudes.

HYDREUS. In Astronomy. A southern constellation.

Hygieia (Gr. *ὑγιεία, health*). The goddess of health, in the Greek Mythology: daughter or wife of Asklepios (*Æsculapius*). Her statues (of which the most celebrated was at Sicyon) sometimes represented her with a large serpent coiled round her body, and elevating its head above her arm to drink of a cup which she held in her hand. Isis, in Egyptian monuments, appears sometimes in a similar attitude.

Hygiene. That branch of medicine which relates to the means of preserving public health.

Hygrology (Gr. *ὕγρος, moist*, and *λόγος*). In Medicine, the doctrine of the humours or fluids of the body.

Hygroma (Gr. *ὕγρως*). A tumour containing serum or other non-purulent fluid.

Hygrometer (Gr. *ὕγρος*, and *μέτρον, measure*). An instrument for measuring the degrees of moisture or dryness of the atmosphere.

HYGROMETER

Variations in the state of the atmosphere with respect to moisture and dryness are manifested by a great variety of phenomena; and accordingly numerous contrivances have been proposed for ascertaining the amounts of those variations by referring them to some conventional scale. All such contrivances are called *hygrometers*; but though the variety of form that may be given to them, or of substances that may be employed, is endless, they may all be referred to two classes; namely, 1st, those which act on the principle of *absorption*; and, 2nd, those which act on the principle of *condensation*.

1. *Hygrometers on the Principle of Absorption*.—Many substances in each of the three kingdoms of nature absorb moisture from the atmosphere with greater or less avidity, and thereby suffer some change in their dimensions, or weight, or some of their physical properties. Animal fibre is softened and relaxed, and consequently elongated, by the absorption of moisture. Cords composed of twisted vegetable substances are swollen, and thereby shortened, when penetrated by humidity; and the alternate expansion and shrinking of most kinds of wood, especially when used in cabinet work, and after the natural sap has been evaporated, is a phenomenon with which everyone is familiar. Many mineral substances absorb moisture readily, and thereby obtain an increase of weight. Now it is evident that any of these changes, either of dimension or of weight, may be regarded as the measure of the quantity of moisture absorbed, from which the quantity of water existing in the atmosphere in the state of vapour is inferred; but many, indeed the far greater part of them, are so small in amount, or take place so slowly, that they afford no certain indication of the actual state of the atmosphere at any particular moment. In fact, all contrivances which depend upon absorption have been successively abandoned as incapable of affording reliable indications.

2. *Hygrometers on the Principle of Condensation*.—The instruments of this class are of a far more refined nature than those which we have been describing. In order to give an idea of the general principle on which they depend, let us conceive a glass jar, having its sides perfectly clean and transparent, to be filled with water, and placed on a table in a room where the temperature is, for example, 60°, the temperature of the water being the same as that of the room. Let us next suppose pieces of ice, or a freezing mixture, to be thrown into the water, whereby the water is gradually cooled down to 55, 50, 45, &c. degrees. As the process of cooling goes on, there is a certain instant at which the jar loses its transparency, or becomes dim; and on attentively examining the phenomenon, it is found to be caused by a very fine dew or deposition of aqueous vapour on the external surface of the vessel. The precise temperature of the water, and consequently of the vessel, at the instant when this deposition begins to be formed, is called the *dew point*, and is capable of being noted with great precision.

Now this temperature is evidently that to which, if the air were cooled down, under the same pressure, it would be completely saturated with moisture, and ready to deposit dew on any body in the least degree colder than itself. The difference, therefore, between the temperature of the air and the temperature of the water in the vessel when the dew begins to be formed, will afford an indication of the dryness of the air, or of its remoteness from the state of complete saturation.

But the observation which has now been described is capable of affording far more interesting and precise results than a mere indication of the comparative dryness or moisture of the atmosphere. With the help of tables of the elastic force of aqueous vapour at different temperatures, it gives the means of determining the absolute weight of the aqueous vapour diffused through any given volume of air, the proportion of vapour existing in that volume to the quantity that would be required to saturate it, and of measuring the force and amount of evaporation.

The elastic force of aqueous vapour at the boiling point of water is evidently equal to the pressure of the atmosphere. This may be assumed as corresponding to a column of mercury 30 inches in height. Dr. Dalton, in the fifth volume of the *Manchester Memoirs*, has given the details of a valuable set of experiments by which he ascertained the elastic force of vapour from water at every degree between its freezing and boiling points, in terms of the column of mercury which it is capable of supporting. As the same experiments have since been frequently repeated, and the different results present all the accordance which can be expected in so delicate an investigation, the tension of vapour at the different temperatures may be regarded as sufficiently well determined. Supposing, then, we have a table exhibiting the elasticity or tension corresponding to every degree of the thermometer, the weight of a given volume of vapour, for example a cubic foot, may be determined as follows:—

Steam at 212°, and under a pressure of 30 inches of mercury, is 1,700 times lighter than an equal bulk of water at its greatest density, or a temperature of about 40°, and a cubic foot of water at that temperature weighs 437,272 grains; the weight, therefore, of a cubic foot of steam at that temperature and pressure is $437,272 \div 1,700 = 257.218$ grains. Hence we may find the weight of an equal bulk of vapour of the same temperature under any other given pressure, suppose 0.56 of an inch; for the density being directly as the pressure, we have 30 in. : 0.56 in. :: 257.218 grs. : 4.801 grs., which is the weight required.

Having found the weight of a cubic foot of vapour under a pressure of 0.56 of an inch, and at the temperature 212°, we may find its weight under the same pressure at any other temperature, suppose 60°. It is ascertained by experiment that all æriform bodies, whether vapours or gases, expand the 1-480th part of

HYGROMETER

their volume for every accession of temperature equivalent to one degree of Fahrenheit's scale; therefore, reckoning a volume of gas at 32° as unity, its volume at 60° is to its volume at 212° as $1 + \frac{28}{480}$ is to $1 + \frac{180}{480}$; or as 1·058 : 1·375; and the density and weight being inversely as the volume, we have

$$1\cdot058 : 1\cdot375 :: 4\cdot801 \text{ grs.} : 6\cdot222 \text{ grs.}$$

for the weight of a cubic foot of vapour at temperature 60°, and under a pressure of 0·56 of an inch of the mercurial column.

The following table, abridged from Daniell's *Meteorological Essays*, shows the force or tension, weight, and expansion of aqueous vapour, at different temperatures on Fahrenheit's scale:—

Temp.	Force	Weight of a Cubic Foot	Expansion
0	·068	·856	·9334
5	·083	1·084	·9438
10	·098	1·208	·9542
15	·119	1·451	·9646
20	·140	1·688	·9750
25	·170	2·028	·9855
30	·200	2·361	·9959
35	·240	2·805	1·0062
40	·280	3·239	1·0166
45	·340	3·893	1·0270
50	·400	4·535	1·0375
55	·476	5·342	1·0479
60	·560	6·222	1·0583
65	·657	7·230	1·0687
70	·770	8·392	1·0791
75	·906	9·780	1·0895
80	1·060	11·333	1·1000
85	1·235	13·081	1·1104
90	1·430	15·005	1·1208
95	1·636	17·009	1·1312
212	30·000	257·218	1·3749

Having explained the principle of the condensation hygrometer, we will now describe one or two of the forms under which it has been most frequently constructed. Daniell's hygrometer is represented in the annexed

figure. *a* and *b* are two thin glass balls of $1\frac{1}{4}$ inch diameter, connected together by a tube having a bore about one-fourth of an inch. The tube is bent at right angles over the two

balls, and the arm *b c* contains a small thermometer *d e*, whose bulb, which should be of a lengthened form, descends into the ball *b*. This ball having been about two-thirds filled with ether, is heated over a lamp till the fluid boils, and the vapour issues from the capillary tube *f* which terminates the ball *a*. The vapour having expelled the air from both balls, the capillary tube is hermetically closed by the flame of a lamp. The other ball *a* is now to be covered with a piece of muslin. The stand *g h* is of brass, and the transverse socket *i* is made to hold the glass tube in the manner of a spring, allowing it to turn and be taken out with little difficulty. A small thermometer *k l* is inserted into the pillar of the stand. The manner of using the instrument is this: After having driven all the ether into the ball *b* by the heat of the hand, it is to be placed at an open window, or out of doors, with the ball *b* so situated that the surface of the liquid may be on a level with the eye of the observer. A little ether is then to be dropped on the covered ball. Evaporation immediately takes place, which, producing cold upon the ball *a*, causes a rapid and continuous condensation of the ethereal vapour in the interior of the instrument. The consequent evaporation from the included ether produces a depression of temperature in the ball *b*, the degree of which is measured by the thermometer *d e*. This action is almost instantaneous, and the thermometer begins to fall in two seconds after the ether has been dropped. A depression of 30° or 40° is easily produced, and the ether is sometimes observed to boil and the thermometer to be driven below zero of Fahrenheit's scale. The artificial cold thus produced causes a condensation of the atmospheric vapour upon the ball *b*, which first makes its appearance in a thin ring of dew coincident with the surface of the ether. The degree at which this takes place must be carefully noted. In very damp or windy weather the ether should be very slowly dropped upon the ball, otherwise the descent of the thermometer will be so rapid as to render it extremely difficult to be certain of the degree. In dry weather, on the contrary, the ball requires to be well wetted more than once, to produce the requisite degree of cold. (Daniell's *Meteorological Essays*.)

A modification of Daniell's hygrometer has been proposed by Regnault, and is known as *Regnault's hygrometer*. In this instrument air is drawn through a silver-coated glass tube containing ether. The evaporation of the ether caused by the current of air produces the necessary depression of temperature, and the first deposition of dew is readily seen upon the polished silver surface. A thermometer, the bulb of which is always immersed in the ether, gives the temperature of the dew point, as in Daniell's hygrometer.

Of the various methods which have been proposed for ascertaining the hygrometric condition of the atmosphere, that which consists in deducing the tension of the aqueous vapour

HYGROMETER

contained in it from the temperatures indicated by two contiguous thermometers, one having its bulb kept wet, while that of the other is dry, is, perhaps, the most generally convenient, and is accordingly that which is usually adopted in meteorological observations. The apparatus has been called a *psychrometer*, though the term, from its etymology, might be applied with equal propriety to any other hygrometer or instrument for measuring the quantity of vapour existing in air.

The relation between the tension, or the elastic force of aqueous vapour, and the temperature (a relation which is the subject of experiment) is supposed to be known for all temperatures under consideration, and exhibited in a table. Hence, to determine the elastic force of the vapour existing in the atmosphere at a given temperature, is the same problem as to determine the degree of temperature to which, if the air were cooled down, it would be saturated with the same quantity of vapour as it actually contains, and begin to deposit moisture; and, reciprocally, if this temperature, which is that of the *dew point*, be determined, the tension of the vapour existing in the air becomes known from the previously ascertained relation between the tension and the temperature of aqueous vapour. Tables of the numerical expression of this relation were constructed by Dalton, and are given in most works which treat of the subject. [VAPOUR.]

Objections of various kinds, theoretical and practical, have been raised to the results obtained by this method. The fundamental principle adopted by August is, that the whole of the air which supplies heat to the wet bulb falls to the temperature of that bulb, and becomes completely saturated with moisture. But it seems more probable that the air coming into contact with the bulb does not quite take the temperature of the bulb, and that the saturation is not complete. Regnault remarks that the ratio of the quantity of heat which the air takes from the bulb by the vaporisation of the water to the quantity which it loses in being cooled is probably not constant, but so much the greater as the air is drier, because dry air absorbs moisture with greater avidity than when it is nearly saturated. Another objection is that the heat which is absorbed in converting the water on the wet bulb into vapour is not supplied exclusively by the surrounding air, but in some measure by the radiation from objects around (for example, the frame to which the thermometers are attached, or the dry bulb itself if too near), the influence of which it is perhaps impossible altogether to eliminate. Other objections are founded on the considerable uncertainty as to the numerical values of some of the elements which enter into the formula, and especially with respect to the heat absorbed by water when vaporised in air. Regnault, therefore, considers that the safest course is to determine the coefficients of the formula by direct experiments under determinate conditions. One means of accom-

HYLOBIUS

plishing this is to compare the results of a large number of observations with the temperatures of the dew point ascertained directly by simultaneous observations with a Daniell's hygrometer; but as this instrument itself cannot be relied on with certainty, the only sure method would seem to be that of separating the moisture from the air and determining their proportions by actually weighing them.

The formula for computing the temperature of the dew point, from observations of a dry and wet bulb thermometer, was first investigated by Professor August, of Berlin, and is given in his work *Ueber die Fortschritte der Hygrometrie* (Berlin 1830), the same in form as the above, but with slightly different constants. There is also an investigation on the same principle, and leading to the same results, by Dr. Apjohn, in the *Dublin Transactions* for 1834 and 1836, and tables have been constructed by Colonel Boileau for facilitating the computation of the formula. But the fullest and best information on the subject is contained in a paper by Regnault, published in the *Annales de Chimie et de Physique* (3me series, tome xv. Paris 1845).

Hygrometric. This term is commonly applied to substances which readily become moist and dry with corresponding changes in the state of the atmosphere, or which readily absorb and retain moisture. Seaweed, several saline substances, porous clays, potash and its carbonate, chloride of calcium, sulphuric acid, are in this sense of the term said to be hygrometric.

Hygroscope (Gr. *ὕψος*, and *σκοπέω*, *I view*). An instrument by means of which changes in the condition of the atmosphere with respect to moisture are observed. See HYGROMETER, by which the same changes are measured.

Hyæosaurus (Gr. *ὑλη*, *wood*, and *σαῦρος*, *a lizard*). A name given by Dr. Mantell to an extinct gigantic genus of reptiles, the fossil remains of which he has discovered in the wealden strata of Sussex.

Hyliism (Gr. *ὑλη*). In Metaphysics, the theory which regards matter, as the original principle of evil, in opposition to the good spirit. This theory lay at the root of the Manichean philosophy: it reappears under a slightly different form in Parseism, which holds that the universe was created by two rival powers, Ormuzd and Ahriman, or Light and Darkness, the latter producing some evil thing for every good thing made by the former. [DUALISM; VEITRA.]

Hylobius (Gr. *ὑλη*, and *βλος*, *life*). A genus of Tetramerous Coleoptera, belonging to the *Curculionidae*, or family of weevils, and noted for the ravages committed by one species, *Hylobius abietis* (*Curculio abietis* and *Curculio pini* of Linnæus), upon firs and larches, especially in young plantations. This insect varies from five to nine lines in length, is of a pitchy black colour, with numerous yellow spots on the elytra. It has been found in the pine woods

HYLONOMUS

of Shropshire, the north of England, and Scotland.

Hylonemus (Gr. *ὄλονμος*, living in the woods). A genus of probably Ganocephalous Reptilia, which has been discovered by Dr. Dawson in the carboniferous strata of the South Joggins coalfield, in Nova Scotia. The remains were found with those of a land-snail, a myriapodous annelide, a small ganocephalous reptile, the *Dendroperon acadianum*, with other fossils in the hollow trunk of one of the fossil trees or *Sigillaria* of the coal deposits. The remains of *Hylonemus*, of which the jaws, dermal covering, and phalangeal bones have been satisfactorily identified, indicate the existence of a reptile during the carboniferous age allied in its general affinities to *Archegosaurus* and the *Ganocephala*.

Hylōoism (Gr. *ῥλν*, wood, used by ancient philosophers to signify the abstract idea of matter, and (*ωψ*, life). In Philosophy, strictly the doctrine that matter lives. Some writers have confined this name to the tenet of the *anima mundi*, or soul of the world; others to the theory of a peculiar life residing in the whole of nature, approaching, therefore, in this sense to pantheism. This life is either merely organic or actually sentient: the latter notion has been also called *hylopathism*. (See the remarks on Cudworth's Intellectual System in Hallam's *Literature of Europe*, iv. 188; and Ersch and Gruber's *Encyclopedia*.)

Hymen (Lat.; Gr. *ῥμν*). In Greek Mythology, the god of marriage: represented in the earlier traditions as originally a mortal. The reasons for his invocation are very variously given; some saying that it arose from the happiness of his marriage, others attributing it to a desire of avoiding the evil omen of his death on the day of his marriage. *Hymenal* is used to signify a song or ode composed in celebration of a marriage. (Cat. Carm. 61, 62.)

Hymenæa (Lat. from Hymen). The West Indian Locust-tree, or Algaroba, belongs to this genus of *Leguminosæ*. It is called *H. Courbaril*, and forms an enormous tree, remarkable for the buttresses naturally formed at the base of its stem. The timber is hard and close-grained; and the bark, which is thick but light, is used by the Indians for making canoes; while a valuable resin, resembling Anime, exudes from the trunk.

Hymenium. In Botany, a term used, in describing fungi, to denote that part in which the sporules immediately lie. It is commonly called the *gills* in the genus *Agaricus*; but in *Boletus* it is a corky or spongy substance pierced full of holes, and in other genera presents a variety of peculiar appearances.

Hymenopterans, **Hymenoptera** (Gr. *ῥμν*, a membrane, and *πτερον*, a wing). An order of mandibulate insects, comprehending those which have four membranous wings with few nervures. Latreille divides this order into the following sections and tribes:—

1. **TERREBRANTIA**: Abdomen of the females furnished with a saw or borer.

HYPALLAGE

a. **SECURIFERA**: Abdomen sessile, furnished with a saw; larvæ with feet.

b. **PUPIVORA**: Abdomen pedunculated, furnished with a borer; larvæ footless.

2. **ACULEATA**: Abdomen of the females armed with a sting.

a. **HETEROGYNA**: Females wingless.

b. **FOSFORA**: Females winged, wings not folded; basal joint of posterior tarsi simple.

c. **DIPLOPTERA**: females winged, wings folded.

d. **MELLIFERA**: Females winged, wings not folded; posterior tarsi enlarged, and converted into a polliniferous organ.

(See the above terms; and **APIS** and **FORMICA**.)

Hymn (Gr. *ῥμνος*). An ode in praise of the Deity, or some divine personage. The earliest Greek hymns are those which are commonly known as the Homeric hymns. They are, with one exception, in heroic verse, and their contents, for the most part, are narrations of the events in the mythological history of the respective gods and goddesses to whom they are dedicated, related in an encomiastic strain. In modern literature, hymns are pieces of sacred poetry intended to be sung in churches; of which the Psalms of David, the most ancient pieces of poetry, properly so called, on record (except the book of Job), furnish the chief example and model. St. Hilary, bishop of Poitiers in the fourth century, is said to have been the first who composed hymns to be sung in churches. The Latin hymns of the Roman Catholic church are well known, from the exquisite music to which they have been united. (As to the classical hymns and hymnographers, see the *Mém. de l'Acad. des Inscriptions*, vols. xii. and xvi.)

Hyoides (from the Greek letter *υ*, and *ειδος*, likeness). A bone situated between the root of the tongue and the larynx is called the *os hyoides*, or hyoid bone, from its supposed resemblance in shape to the letter *υ* or upsilon.

Hyoscyamia. The active principle or alkaloid of the common henbane (*Hyoscyamus niger*).

Hyoscyamus (Gr. *ὁσκόμαμος*, literally hog-bean). The genus of the Henbane, which is *H. niger*. It belongs to the *Solanaceæ*. [**HENBANE**.]

Hypæthral (Gr. *ὑπαίθριος*, from *ὑπό*, and *αἶθρ*, ether). In Architecture, a building or temple uncovered by a roof. The temples of this class are arranged by Vitruvius under the seventh order, having six columns in the front and rear, and being surrounded with a dipteral, or a double portico. The famous temple of Neptune at Pæstum, still remaining, is an example of this species of building.

Hypallage (Gr. *ὑπαλλαγή*, from *ὑπάλλασσω*, I change). In Grammar and Rhetoric, a species of inversion, in which not only the natural or customary succession of words is changed, but the sense presents a species of transposition, in which predicates are transferred from their proper subject to another. Such examples as

HYPANTHIUM

'gladium vagina vacuum,' *the sword empty of the scabbard*, 'in nova fœct animus mutatas dicere formas corpora,' where the adjective 'new' is transferred from 'form' to 'body,' present striking instances of this figure; but although such deviations from the natural sense could not be admitted in modern language, similar locutions are not wholly wanting among ourselves.

Hypanthium or **Hypanthodium** (Gr. ὑπό, and ἄνθος, a flower). In Botany, a fleshy receptacle not enclosed in an involucre.

Hypapophysis (Gr. ὑπό, and ἀπόφυσις, a process). In Anatomy, the usually exogenous process which descends from the lower part of the centrum or vertebral body: it is sometimes single, as in the cervical vertebrae of the lizard; sometimes perforated, as in certain cervical vertebrae of birds; sometimes double in a transverse pair, as in the caudal vertebrae of certain mammals, where they support the hæmal arch.

Hyper (Gr. ὑπέρ, over, above). In Chemical nomenclature, this prefix is sometimes used to denote acids containing more oxygen than those to which the term *per* is prefixed.

Hyper Space. In Geometry, imaginary space of more than three dimensions.

Hyperæmia (Gr. ὑπέρ, and αἷμα, blood). Congestion of blood in any part.

Hyperbola (Gr. ὑπερβολή). In Geometry, one of the conic sections, formed by cutting a cone by a plane which is so inclined to the axis that when produced it cuts also the opposite cone, or the cone which is the continuation of the former on the opposite side of the vertex. [CONIC SECTIONS.]

The hyperbola is also a curve of the second order, characterised by having two real and distinct asymptotes. [QUADRATIC.] The ordinary definition of the hyperbola is as follows:—

If two points *F* and *f* be given in a plane, and a point *D* be conceived to move around them in such a manner that the difference between the two distances *DF* and *Df* is always constant, the point *D* will describe on the plane an hyperbola *DAM*. The two symmetrical

branches of which the curve consists are obtained by assuming first one of the given points *F*, and then the other *f*, as that to which the moving point is nearest. The points *F* and *f* are the foci of the hyperbola; and *C*, which bisects the distance between the foci, is its centre. The line *AA'* is the major or transverse axis, its extremities *A* and *A'* the vertices, and a straight line *BB'*, passing through the centre, perpendicular to *AA'*, and of such a length that the square of its half *CB* or *CB'* is equal to the difference between the squares of *CF* and *CA*, is the minor or conjugate axis. The curve

HYPERBOLIC CYLINDER

may be described mechanically as follows: Let one end of a string be fastened to *F*, and the other to *K*, the extremity of a ruler *fDK*; and let the difference between the length of the ruler and of the string be equal to *AA'*. Let the other end of the ruler be fixed to the point *f*, and let the ruler be made to revolve about *f* as a centre in the plane in which the axes are situated, while the string is stretched by means of a pin *D*, so that the part of it between *K* and *D* is applied close to the edge of the ruler: the point of the pin will, by its motion, trace a branch *DAM* of the hyperbola required; and if the ruler be made to revolve about the other focus *F*, while the end of the string is fastened to *f*, the opposite branch of the hyperbola will be described by the pin *D'*.

All algebraic expressions which have reference to the ellipse become applicable to the hyperbola by changing b^2 into $-b^2$. Thus, referred to the centre as origin, the equation of the hyperbola is

$$\frac{x^2}{a^2} - \frac{y^2}{b^2} = 1,$$

where $2a$ is the major, and $2b$ the conjugate axis; the equations of the asymptotes are

$$\frac{x}{a} - \frac{y}{b} = 0 \quad \text{and} \quad \frac{x}{a} + \frac{y}{b} = 0.$$

Referred to a vertex *A*, the equation of the curve assumes the form

$$y^2 = p x + \frac{b^2}{a^2} x^2,$$

where *p* is the parameter (*latus rectum*) or double ordinate *PP'* through a focus *F*. The hyperbola derives its name from the property, expressed by this equation, that the square on any ordinate *HD* exceeds, or differs in *excess* from, the rectangle under the corresponding abscissa *AH* and parameter *PP'*. The equation of the hyperbola referred to its asymptotes assumes the simple form $4xy = a^2 + b^2$, whence we learn that the area of the parallelogram formed by the coordinates is constant. When the asymptotes are perpendicular to each other, the hyperbola is said to be *equilateral*, its two axes being also equal. Curves represented by equations of the form

$$x^m y^n = a \text{ constant}$$

are sometimes termed hyperbolas of higher order; they possess many curious properties.

Hyperbole (Gr. ὑπερβολή, excess). In Rhetoric, a figure by which expressions are used signifying more than it is intended to represent to the hearer or reader; as when thoughts and sentiments are clothed in t. mid language, or ideas are brought forward which in themselves are incredible, in order to induce a belief or something less than that which is offered. Exaggeration is hyperbole applied to narrative, when false assertions are added to true in order to increase the impression made by them.

Hyperbolic Cylinder. A surface generated by the motion of a line which constantly remains parallel to itself and has a hyperbola

HYPERBOLIC LOGARITHMS

for its director. All its plane sections are hyperbolas.

Hyperbolic Logarithms. A system of logarithms; so called because the numbers express the areas between the asymptote and curve of the hyperbola, those areas being limited by ordinates parallel to the other asymptote, and the ordinates decreasing in geometrical progression. But as such areas may be made to denote any system of logarithms whatever, the denomination is not correct. In place of hyperbolic logarithm, the term *Napierian logarithm* (from the inventor of the logarithms, Baron Napier) is more frequently used by Continental writers, and *natural logarithm* by English ones. [LOGARITHM.]

Hyperbolic Paraboloid. A ruled surface of the second order, whose plane sections are either hyperbolas or parabolas. For the method of generating such a surface, see QUADRIC. The equation of the surface may be reduced to the form $z = \frac{x^2}{a} - \frac{y^2}{b}$, whence it is obvious that the plane of the axes x and y meets the surface in the two lines

$$x\sqrt{b} + y\sqrt{a} = 0;$$

all sections parallel to this plane are hyperbolas, the transverse axes of which are parallel to the x or y axis, according as the section is made above or below the plane (xy). All sections through the z axis are parabolas, the convexities of which are turned upwards or downwards, according as the plane cuts through one or the other of the adjacent angles contained by the planes $x\sqrt{b} + y\sqrt{a} = 0$. A rough illustration is presented by the surface of a saddle. When $a=b$ the paraboloid is said to be *equilateral*; its equation, to other rectangular axes, may be written in the form $xy = az$. The axes of x and y are now lines on the surface, and the coordinate planes, perpendicular to them, meet the surface again in two infinitely distant lines; in other words, they are the *asymptotic planes*. The equilateral paraboloid may obviously be generated by a line sliding along and turning around a director to which it always remains perpendicular; it is therefore a *conoidal surface*. [CONOID.]

Hyperbolic Point. A point on a surface, at which the indicatrix is a hyperbola. Such a point is a double point on the section of the surface made by the tangent plane. The two real tangents to the section at this double point are the inflexional tangents at the hyperbolic point. [INDICATRIX.]

Hyperbolic or Reciprocal Spiral. The inverse of the spiral of Archimedes. Its equation is $r = \frac{a}{\theta}$, and consequently it belongs

to the family represented by the general equation $r = a\theta^n$. [SPIRAL OF ARCHIMEDES.] The hyperbolic spiral was first proposed by James Bernoulli; it has a rectilinear asymptote AB from the infinitely distant point of which it

HYPERBOREANS

may be said to start, and to arrive at the pole after an infinite number of convolutions. The polar subtangent of this spiral is constant.

The hyperbolic spiral is also the reciprocal of the INVOLUTE OF THE CIRCLE. The properties of this and of allied spirals are given in most works on Algebraic Geometry.

Hyperboloid. A surface of the second order, which is cut by certain planes in hyperbolas. [QUADRIC.] Two kinds of hyperboloids are distinguished. The one, whose equation is

$$\frac{x^2}{a^2} + \frac{y^2}{b^2} - \frac{z^2}{c^2} = 1,$$

is called the *hyperboloid of one sheet*; the other, represented by the equation

$$\frac{x^2}{a^2} - \frac{y^2}{b^2} - \frac{z^2}{c^2} = 1,$$

bears the name of *hyperboloid of two sheets*, from the fact that certain planes in space do not intersect the surface. In the first the plane sections parallel to the axes a, c , as well as those parallel to b, c , are hyperbolas; whilst those parallel to a, b are ellipses. In the hyperboloid of two sheets, planes parallel to a, b and a, c give hyperbolic sections, whilst those parallel to b, c are either *real* or *imaginary* ellipses. The hyperboloid of one sheet is a *ruled surface*, that is to say, at every point of it a straight-edge may be applied to the surface in two distinct directions [QUADRIC]; the hyperboloid of two sheets possesses no such property. Replacing 1 by 0 on the left of the above equations, they represent the asymptotic cones of the respective hyperboloids. The distinction between the two hyperboloids is clearest in the case of *hyperboloids of revolution*; when $a=b$ in the first, or when $b=c$ in the second equation.

Hyperboloid of Revolution. A surface generated by the rotation of a hyperbola about one of its axes. If the axes of rotation coincide with the *conjugate axis* of the hyperbola, the generated surface is a *hyperboloid of one sheet*, whilst a *hyperboloid of two sheets* is generated by the rotation of a hyperbola about its *transverse axis*. [HYPERBOLOID.] All hyperboloids of one sheet being ruled surfaces [QUADRIC], those of revolution may be generated by the rotation of a line about any axis not in the same plane with itself. A rough illustration of such a surface is obtained by applying torsion to a bundle of needles held together, in the centre, by a string.

Hyperboreans (Gr. οἱ Ὑπερβόρειοι). Literally, people living beyond Boreas or the north wind, i.e. in the extreme north. In the mind of Herodotus (iv. 32) a vague feeling survived that this people, leading a life of unbroken happiness, in regions beyond the frost and snow, was an actual nation, of whose exist-

HYPERCATALECTIC

once he needed only better evidence than that which he possessed. In the mythology of Pindar (*Pyth.* x. 55), they are a happy race, into whose home strife and sorrow, war and sickness, cannot enter, where Apollo and the Muses wake undying harmonies, and where the heads of all glisten with wreaths of golden laurel. The myth is connected with that of Perseus, the destroyer, who comes to their glorious garden after having slain Medusa, and flying from her Gorgon sisters, who only just fail to seize him, as he eludes their grasp. This chase, in mythical speech, denoted the pursuit of the sun by the dark shadows of the deathlike night, which he has slain; while his escape signifies the rising of the sun into the upper regions of the sky, where the morning weaves her fairy network of delicate cirri clouds. Thus the Hyperborean gardens resolve themselves into the mysterious web of Penelope (the weaver), undone each day, and reproduced on the rising or setting of the sun. Hence, with singular fidelity to the original mythical phrase, Penelope, in the *Odyssey*, says that she will know whether Odysseus is her husband, by his recognition of the woven-work which he wrought for her in the days of their early love (i. e. in the morning). It may be noticed that the Hyperboreans of Pindar wear wreaths of Daphné (laurel); and thus the myth is connected with the beautiful legend of Daphné, or Dahaná, the Dawn, who vanishes away when pursued by her lover, Phœbus, the Sun.

For later speculations and dreams arising out of the myth of the Hyperboreans, see Sir G. C. Lewis, *Astronomy of the Ancients*, p. 490 &c.

Hypercatalectic (Gr. ὑπέρ, above, and καταληκτικός, deficient). In Greek and Latin poetry, a verse exceeding its proper length by one syllable.

Hypercatharsis (Gr. ὑπέρ, and κάθαρσις, cleansing). Excessive purging.

Hypercriticism (Gr. ὑπέρ, and κριτικός, critical). Consists in viewing the works of an author in an ungenerous spirit, exaggerating minor defects, and overlooking or undervaluing such merits or beauties as might fairly be considered to outweigh the former.

Hyperdeterminants. The name first given, by their discoverer, Prof. Cayley (*Cambridge and Dublin Math. Journal*, vol. i., and *Crelle's Journal*, vol. xxx.), to the derivative functions, now always referred to as *invariants*. [INVARIANTS.] The terms *hyperdeterminant calculus* and *hyperdeterminant notation*, however, are still in use. The latter consists of such symbols as $\bar{1}2$, $\bar{1}23$ &c. . . which are respectively abbreviations of the operative symbols

$$\left| \frac{\partial}{\partial x_1}, \frac{\partial}{\partial y_1} \right|, \left| \frac{\partial}{\partial x_1}, \frac{\partial}{\partial y_1}, \frac{\partial}{\partial x_2} \right|, \&c.$$

$$\left| \frac{\partial}{\partial x_2}, \frac{\partial}{\partial y_2} \right|, \left| \frac{\partial}{\partial x_2}, \frac{\partial}{\partial y_2}, \frac{\partial}{\partial x_3} \right|, \left| \frac{\partial}{\partial x_3}, \frac{\partial}{\partial y_3} \right|, \&c.$$

HYPERGEOMETRIC SERIES

The calculus in question consists in operating with such symbols upon the product UV &c. of given quantities U , V , W , &c., respectively functions of the cogredient variables x_1, y_1 &c.; x_2, y_2 &c.; x_3, y_3 &c.; and the results of such operations are always either covariants or invariants of the system. Thus, if we operate upon the product UV , where

$$U = ax_1^2 + 2bx_1y_1 + cy_1^2, \\ V = dx_2^2 + 2bx_2y_2 + cy_2^2,$$

with the symbol $\bar{1}2$, or written in full,

$$\frac{\partial^2}{\partial x_1^2} \cdot \frac{\partial^2}{\partial y_2^2} - 2 \frac{\partial^2}{\partial x_1 \partial y_1} \cdot \frac{\partial^2}{\partial x_2 \partial y_2} + \frac{\partial^2}{\partial x_2^2} \cdot \frac{\partial^2}{\partial y_1^2},$$

we obtain the invariant $ac' - 2bb' + ca'$. Or more generally, if we operate with this symbol upon the product of any two quantities, U and V , whatever, we shall have a covariant in two sets of variables, or simply a covariant of the quantities U and V , if, after differentiation, all suffixes are suppressed. Thus

$$\frac{\partial^2 U}{\partial x^2} \cdot \frac{\partial^2 V}{\partial y^2} - 2 \frac{\partial^2 U}{\partial x \partial y} \cdot \frac{\partial^2 V}{\partial x \partial y} + \frac{\partial^2 U}{\partial y^2} \cdot \frac{\partial^2 V}{\partial x^2}$$

is always either a covariant or invariant of the system U , V , and hence also when U and V are identical

$$\frac{\partial^2 U}{\partial x^2} \cdot \frac{\partial^2 U}{\partial y^2} - \left(\frac{\partial^2 U}{\partial x \partial y} \right)^2$$

is a covariant (the Hessian) of the quantic U . Further details, and useful exercises in the hyperdeterminant calculus, are given in Salmon's *Higher Algebra*.

Hyperelliptic Integral. The integral of an expression, which involves the square root of a rational and integral algebraical function of an order higher than the fourth. [ELLIPTIC INTEGRAL.] Such integrals are also called *ultra-elliptic*.

Hypergeometric Series. A series which transcends a geometric one. The ordinary form of such a series is

$$1 + \frac{\alpha}{1 \cdot \gamma} x + \frac{\alpha(\alpha+1) \cdot \beta(\beta+1)}{1 \cdot 2 \cdot \gamma(\gamma+1)} x^2 + \&c.$$

for which Gauss uses the symbol $F(\alpha, \beta, \gamma, x)$, and Cayley has proposed the modification

$$F \left(\begin{matrix} \alpha, \beta \\ 1, \gamma \end{matrix}; x \right)$$

in order to extend the same notation to ultra-hypergeometric series, such as

$$F \left(\begin{matrix} \alpha, \beta, \gamma, \dots \\ 1, \delta, \epsilon, \dots \end{matrix}; x \right).$$

If we put

$$y = \int_0^1 u^{\beta-1} (1-u)^{\gamma-\beta-1} (1-xu)^{-\alpha} du,$$

it will be found that

$$F \left(\begin{matrix} \alpha, \beta \\ 1, \gamma \end{matrix}; x \right) = \frac{y}{B(\beta, \gamma-\beta)};$$

where B denotes a *Eulerian integral*, whilst y

HYPERICACEÆ

satisfies the linear partial differential equation of the second order

$$x(1-x)\frac{d^2y}{dx^2} + [\gamma - (\alpha + \beta + 1)x]\frac{dy}{dx} - \alpha\beta\gamma = 0.$$

(Euler's *Institutiones Cal. Integ.* vol. ii.) Investigations on Hypergeometric Series will be found in Gauss' and Jacobi's collected works; a valuable memoir on the subject by Kummer was published in Crelle's *Journal*, vol. xv. 1836.

Hypericaceæ (Hypericum, one of the genera). A natural order of Exogenous plants belonging to the Guttifera alliance. They usually have yellow flowers with the petals wider on one side than the other, and marked with black dots; while the leaves are in many cases marked with transparent dots. They are usually strong-scented and astringent. Some of them have coppery red flowers, and yield a resinous substance resembling gamboge.

Hypericum (Gr. *ὑπέρικον*, or *ὑπέρικον*, from *ὑπελκν*, *heath*). The *Hypericum perforatum*, or St. John's Wort, was much esteemed by the ancients as an anodyne.

Hyperion (Gr. *Ἥριον*). In the *Theogony* of Hesiod, Hyperion, or the lofty one, is a son of Uranus (Heaven) and Gæa (Earth), and the father, by his sister Theia, of Helios (the Sun), Seléné (the Moon) and Eos (the Morning). But in the Homeric poems the word is a mere synonym for Helios, and the two names more commonly occur together. From the length of the penultimate syllable, the word is generally regarded as a contraction of Hyperionion, and equivalent to the patronymic form Hyperionides. [TITAN.]

HYPERION. In Astronomy, one of the satellites of Saturn.

Hyperoxymuriates. Combinations of chloric acid were formerly so called: thus, chlorate of potash was called hyperoxymuriate of potash.

Hypersthene (Gr. *ὑπέρ*, and *σθένος*, *strength*). Labrador Hornblende. It is a ferrosilicate of magnesia, with traces of alumina and of lime. It occurs crystalline and massive; it is resplendent, and of a grey-green or reddish hue.

Hyperthyrum (Gr. *ὑπέρθυρον*, from *θύρα*, a door). In Architecture, the lintel of a doorway.

Hyper trophy (Gr. *ὑπέρ*, and *τροφή*, *food*). A term frequently applied to the morbid enlargement of any part of the body. This term ought to be restricted to cases in which a part, though increased in bulk, retains its natural organisation and structure.

Hypha. In describing *Algæ*, denotes the filamentous, fleshy, watery thallus of *Bussacææ*.

Hyphæne (Gr. *ὑψαλως*, to weave). The Doum Palm of Egypt, one of the few plants in this noble family which produce branching trunks, belongs to this genus. It is called *H. thebaica*, and sometimes the Gingerbread-tree, the fibrous mealy husk of the fruit, which is eaten by the poorer classes, tasting like gingerbread. This or some allied species is widely dispersed over tropical Africa.

HYPOCHONDRIASIS

Hyphen (Gr. *ὑφέν*, strictly *ὑφ' ἑν*, in one). In Printing and Writing, a mark or character thus (-), implying that two or more words are connected, as mother-in-law, self-love. In printed books, when a word is divided, the hyphen goes with the part of the word at the end of the first line, never at the beginning of the second.

Hypnotics (Gr. *ὑπνωτικάς*, drowsy). Medicines which induce sleep.

Hypo (Gr. *ὑπό*, under). In Chemical nomenclature, this prefix indicates the presence of a smaller quantity of oxygen than that contained in the acid or compound to which it is prefixed; thus the *hyposulphurous acid* contains less oxygen than the sulphurous, and the *hyposulphuric acid* less oxygen than the sulphuric; and the *hyponitrous acid* less oxygen than the nitrous, &c.

Hypocælia (*ὑπό*, under). Oval ganglionic structures into which the fibres of the prepyramidal tracts of the brain in fishes swell out beneath the optic lobes. Their bulk is increased by added grey matter, variegating their outer surface. In the cod and in some other fishes, they contain a cavity called *hypocælian ventricle*.

Hypocæustum (Gr. *ὑπόκαυστον*, from *ὑπό*, and *καλω*, I burn). In Ancient Architecture, a vaulted apartment from which heat was distributed to the rooms above by means of earthen tubes.

Hypochloric Acid or Peroxide of Chlorine. A green gas evolved when chlorate of potash is acted on by sulphuric acid. It contains one equivalent of chlorine and four of oxygen, and explodes when heated to 212°

Hypochlorous Acid. A yellow unstable gas containing one equivalent of chlorine and one of oxygen. Formed when chlorine is agitated with moist mercuric oxide. It is supposed to be the bleaching agent in the so-called chloride of lime.

Hypochondriasis (Gr. *ὑπό*, under, and *χόνδρος*, cartilage). Uneasiness about the region of the stomach and liver, or of the *hypochondriac region*, is one of the symptoms of this disease. Particular circumstances may induce this disorder in any individual; but it is most commonly met with in persons of sallow or pale complexions, spare habit of body, and dark hair and eyes. Its mental symptoms are low spirits, a groundless apprehension of evil, imaginary local sensations, and erroneous impressions respecting the opinions and sentiments of others, with a tendency to misconstrue their actions; aversion to society; want of mental and bodily energy; seeing persons and things and hearing conversations and noises which are purely imaginary. The bodily symptoms are flatulency and all the other concomitants of indigestion—costiveness, dimness of sight, noises in the ears, want of appetite and sleep in most cases, in few voracity and drowsiness. As this disease is usually connected with imperfect action of the liver, mild aperients, small doses of calomel or blue

HYPOCRATERIFORM

pill, and tonics are to be prescribed; but occasionally more powerful purgatives must be resorted to; and where there is much headache, a blister to the neck, or the loss of a little blood by cupping, or from the arm, may be of service. The regularity of the circulation is often much disturbed, and it is generally necessary to keep the feet warm.

Change of scene and of occupation, cheerful society, moderate exercise of all kinds, and great kindness and attention on the part of the medical adviser, are generally among the essentials in the treatment of this diseased state. But every amusement and relaxation must be carefully proposed and pursued; and though it is generally necessary firmly but gently to remonstrate against the whims and caprices of hypochondriacs, yet sometimes they must be conceded to. When persons are full of evil forebodings and false alarms, it is sometimes well to induce them to keep a diary of their feelings, the perusal of which as they recover, or in their happier moments, is often comforting proof to them of the utter want of foundation of some of their most inveterate notions. Persons who are very irritable and over-anxious, or who, after having been actively engaged in business, retire to a life of ease and idleness, who take no interest in study, amusement, or exercise; and those, again, who have kept bad hours, or who have led debauched lives, or who have studied intensely—are those in whom some of the worst forms of hypochondriasis occur. It is seldom in the most aggravated cases of this disorder that well-grounded hopes of recovery may not be held out, and that its recurrence may not be prevented by timely and firm treatment; but if it be allowed to run its course, it often ends in melancholy.

Hypocrateriform (Gr. *ὕψ*, and *κρατήρ*, a cup). In Botany, that form of a corolla which consists in a cylindrical tube which is longer than the flat-spreading limb, as in the flowers of the genus *Phlox*. It is called in English *salver-shaped*.

Hypocycloid (Gr. *ὕψ*, and *κυκλοειδής*, circular). The curve traced by a point in the circumference of a circle which rolls on the concave side of a fixed circle. When the radius of the rolling circle exceeds that of the fixed circle, the hypocycloid may always be generated as an epicycloid. [EPICYCLOID.] This property was discovered by Euler (*Acta Retrop.* 1784). When the radius *a* of the fixed circle is double that of the rolling one, the hypocycloid coincides with the diameter of the fixed circle. When the radius *a* of the fixed circle is four times that of the rolling circle, the hypocycloid is also algebraic, and has for its equation

$$x^3 + y^3 = a^3.$$

Hypocyst. A Pharmaceutical name of the inspissated juice of the *Cytisus hypocistis*, a parasitical plant on the roots of several species of *cistus* in the South of Europe.

Hypogæous (Gr. *ὕψ*, and *γῆ*, the earth). Literally, *subterranean*. In Botany, it denotes

HYPOSTASIS

all parts in plants which grow beneath the surface of the earth.

Hypogastrium (Gr. *ὕψ*, and *γαστήρ*, the stomach). The middle part of the lower region of the belly.

Hypogene (Gr. *ὕψ*, and *γίνομαι*). A name given by Sir Charles Lyell to a group of rocks formed within the earth, modified probably from regular stratified aqueous rocks, but having lost all their original characteristics before they are presented to us for examination. Granite, porphyries, metamorphic limestone and quartzite, are all of them generally to be regarded as hypogene rocks. They are especially abundant in mountain districts, forming either the highest and geographical axis or the real geological axis of every principal chain.

Hypoglossal Nerves (Gr. *ὕψ*, and *γλῶσσα*, the tongue). The lingual nerves.

Hypogynous (Gr. *ὕψ*, and *γυνή*, a female). In Botany, a term denoting anything growing from below the base of the ovary.

Hypomochlion (Gr. *ὕψ*, and *μόχλιον*, from *μολός*, a lever). In Mechanics, the fulcrum or support of a lever, or the point against which the pressure is exerted. This term is met with only in the old treatises on mechanics; the equivalent term *fulcrum* being now generally used.

Hyponitric Acid. A compound of one atom of nitrogen with four of oxygen. It has really no acid properties, and hence is now generally termed *peroxide of nitrogen*. It is formed on mixing binoxide of nitrogen with half its volume of oxygen, or by heating nitrate of lead. It may be liquefied, and even solidified, by cooling.

Hyponitrous Acid. An acid intermediate between nitric oxide and nitrous acid, composed of 1 equivalent of nitrogen = 14, and 3 of oxygen = 24, the equivalent of the hyponitrous acid, upon the hydrogen scale, being = 38.

Hypophosphorous Acid. An acid composed of 1 atom of phosphorus and 1 of oxygen, or 32 phosphorus + 8 oxygen.

Hypophyllium (Gr. *ὕψ*, and *φύλλον*, a leaf). In Botany, a term invented to denote a petiole that has the form of a small sheath, is destitute of lamina, and surrounds the base of certain small branches, having the appearance of leaves; as in asparagus. It is nothing but a rudimentary leaf.

Hypophyllous. In Botany, applied to bodies which grow on the underside of a leaf.

Hypopium (a term coined from Gr. *ὕψ*, and *πῦον*, pus). A disease of the eye, in which there is an apparent collection of pus under the transparent cornea; that is, in the chamber of the aqueous humour.

Hyposcenium (Gr. *ὕψ*, and *σκήνιον*, from *ὕψ*, and *σκήνῃ*, a scene). In ancient Architecture, the front wall of a theatre, facing the orchestra, from the stage.

Hypostasis (Gr. *ὕψ*, and *στασις*, answering to the Latin substantia). A term used by the Greek fathers to express the distinct personality of the Father, Son, and Holy Ghost. This term is retained by the Latin fathers,

who, like ourselves, had no word which could exactly represent hypostasis, which differs from *ousia*, *substance*, inasmuch as the latter is used for the divine substance, *essence*, or being—that which is common to each of the hypostases, persons, or individual substances which compose the one Godhead.

Hypostatic Union. A term used to signify the union of Christ's human nature with the divine, constituting two natures in one person.

Hyposulphuric Acid. An acid intermediate between the sulphurous and sulphuric acids. It may be regarded as containing 2 atoms of sulphur ($16 \times 2 = 32$), and 5 of oxygen ($8 \times 5 = 40$); or as constituted of 1 atom of sulphurous acid = 32, and 1 of sulphuric acid = 40. In either case its equivalent is 72.

Hyposulphurous Acid. An acid constituted of 2 atoms of sulphur ($16 \times 2 = 32$) and 2 of oxygen ($8 \times 2 = 16$). It is necessary to take this view of composition, its equivalent number being 48.

Hypothecation (Gr. *ὑποθήκη*, a *pledge*). In the Civil Law, an engagement by which the debtor assigns his goods in pledge to a creditor as a security for his debt, without parting with the immediate possession; differing, in this last particular, from the simple pledge. The term *hypothecation* is usually applied to things immovable only (i. e. according to the division of the English law, to things real, things personal savouring of the realty, and choses in action), and not to things movable (i. e. things personal in possession). It answers in general to the English mortgage. [MORTGAGE.]

Hypothenuse (Gr. *ὑποτεννωσα γραμμή*, the *subtending line*). In Geometry, the side opposite the right angle of a right-angled triangle.

Hypothesis (Gr. *ὑπόθεσις*). In a mathematical proposition, this term denotes that which is assumed or granted, and from which the assertion or predicate follows as a consequence. The converse of a proposition is formed by making the predicate hypothesis and the hypothesis predicate. As an example, we have the 47th and 48th propositions of the first book of Euclid. According to the first, if a triangle is right-angled, the square on one side is equal to the sum of the squares on the other two; according to the second, if the sum of the squares on two sides of a triangle is equal to the square on the third side, the triangle is right-angled.

HYPOTHESIS. In Physics and Natural Science, this term denotes a gratuitous supposition to account for some phenomenon or appearance of the natural world. If the hypothesis serves to explain a great number of the circumstances accompanying a phenomenon, it acquires a certain degree of probability; and if all the known circumstances can be deduced from it, the probability becomes very great (it then usually acquires the name of a *theory*), and in the lapse of time may amount to certainty. Thus the hypothesis of the diurnal rotation of the earth and its translation in the ecliptic, imagined by Copernicus to explain the planetary phenomena, has acquired all the characters of

certainly from continual astronomical observation. In like manner, Kepler's hypothesis, that the planets move in elliptic orbits, has been so fully confirmed by subsequent discoveries and computations, that, however doubtful it might be at first, no one who is capable of understanding the evidence can hesitate to receive it as an established law of nature. 'A well-imagined hypothesis,' says Sir John Herschel, 'if it have been suggested by a fair inductive consideration of general laws, can hardly fail at least of enabling us to generalise a step further and group together several such laws under a more universal expression. But this is taking a very limited view of the value and importance of hypotheses. It may happen (and it has happened in the case of the undulatory theory of light) that such a weight of analogy and probability may be accumulated on the side of an hypothesis, that we are compelled to admit one of two things—either that it is an actual statement of what really passes in nature; or that the reality, whatever it be, must run so close a parallel with it as to admit some mode of expression common to both, at least in so far as the phenomena actually known are concerned. Now, this is a very great step, not only for its own sake, as leading us to a high point in mathematical speculation, but for its applications, because whatever conclusions we deduce from an hypothesis so supported must have at least a strong presumption in their favour; and we may be thus led to the trial of many curious experiments, and to the imagining of many useful and important contrivances, which we would never otherwise have thought of, and which, at all events, if verified in practice, are real additions to our stock of knowledge and to the arts of life.' (*Discourse on the Study of Natural Philosophy*.)

Hypotrachelium (Gr. *ὑποτραχήλιον*, from *τράχηλος*, the *neck*). In Architecture, the slenderest part of the shaft of a column, being that immediately below the neck of the capital.

Hypotrochoid (Gr. *ὑπό*, and *τροχός*, *like a wheel*). The curve traced by a point which is fixed relative to a circle rolling on the concave side of a fixed circle. Hypotrochoids bear the same relation to hypocycloids as epitrochoids do to epicycloids. All belong to the family of roulettes, and the hypotrochoid becomes a hypocycloid when the generating point is on the circumference of the rolling circle. The hypotrochoid is an algebraical curve when the circumferences of the two circles are commensurable; in other cases it is transcendental. The most interesting case is when the radius of the fixed circle is double that of the rolling one; the hypotrochoid is then an ellipse, a fact of which advantage is taken in the construction of so-called elliptic compasses. [ELLIPSE.]

Hypotypesis (Gr. *ὑποτύπνωσις*, from *τύπος*, a *type*). In Rhetoric, an animated representation of a scene or event in descriptive language highly enriched with rhetorical figures.

Hypoxidaceæ (Hypoxia, one of the genera). A natural order of epigynous monocotyledons.

HYPSIPRYMNUS

belonging to the Narcissal alliance. They are known by their hexapetaloid flowers, by their six stamens with introrse anthers, and by having the radicle remote from the hilum in their seed. They are not of much importance.

Hypsiprymnus (Gr. *ὕψιπρυμνος*, with *high stern*). A genus of Poëphagous marsupials, of which the Kangaroo Rat (*Hypsiprymnus murinus*) is found in New South Wales. The upper middle incisors are long and produced beyond the small lateral ones. The posterior far surpass the anterior extremities in length. The tail is shorter than the body, and slender.

Hypsometry (Gr. *ὕψος*, *height*, and *μέτρον*, *measure*). The art of measuring height, either relative or absolute, by trigonometry or the barometer.

Hyrcium. An article imported, as a substitute for castor, from the Cape of Good Hope, and derived from one of the species of *Hyraz*.

Hyraotherium (Gr. *ὕραθ*, and *θηρion*, *beast*). A genus of diminutive Perissodactyle mammalia, which flourished in England during the middleocene period. It exhibited the typical dentition (44 teeth). Its nearest affinities were with *Phiolophus* and *Stereognathus*.

Hyraz (Gr. *ὕραθ*, a shrew-mouse). This term is now applied to a genus of small Mammalia which rank next the rhinoceros in the order of their affinities, and are the most diminutive representatives of the Pachydermatous order. The two known species are found in hilly districts at the Cape (*Hyraz capensis*), and in Syria (*Hyraz syriacus*): the latter species is the *cony* of Scripture.

Hyson. A commercial name of one of the varieties of *green tea*. [TRA.]

Hyssopus (Lat.; Gr. *ὕσσωπος*; Heb. *ezób*). A genus of *Labiatae*. *H. officinalis*, the Common Hyssop, is one of the bitter aromatic herbs which were formerly used as a stimulating stomachic, but it is now seldom employed.

Hysteranthus (Gr. *ὕστερος*, *after*, and *ἄνθος*, *a flower*). In Botany, a term denoting the appearance of the leaves after the flowers; as in the almond.

Hysteria (Gr. *ὕστερα*, *the womb*, with which the disease was supposed to be generally con-

I

nected). Hysteria generally attacks unmarried females between the ages of fifteen and thirty-five, coming on with low spirits and anxiety, sickness, short breath, and palpitation, sobbing, and a sense of distension of the bowels, which afterwards seems to concentrate itself in the stomach, and then rise like a ball into the throat (*globus hystericus*), where it produces gasping, stupor, convulsive motions, crying, laughing, hiccough, flow of saliva from the mouth, and delirium: at length the spasms abate, and the person gradually recovers, generally with the expulsion of wind from the stomach. Some of these symptoms are often much more prevalent than others, so that the disorder assumes many forms: it is also very variable in its duration, lasting from an hour or two to one or two days. The treatment varies extremely with the apparent causes of the disorder; sometimes bleeding and depletives, at others stimulants and tonics are required; in mild cases sprinkling with water and applying nasal stimulants give relief. Great attention to the exciting cause, exercise, moderate and judicious amusements and occupations, regular hours, and change of air and scene, are among the best preventives of its recurrence.

Hysteritis. Inflammation of the womb. This dangerous disease generally occurs the second or third day after delivery; it is attended by fever and pain of the part, and requires active antiphlogistic treatment.

Hysterology or **Hysteron Proteron** (Gr. *ὕστερος*, *the latter* of two, and *πρότερος*). In Rhetoric, a figure by which the ordinary course of thought is inverted in expression, and the last put first; as, where objects subsequent in order of time are presented before their antecedents, cause before effect, &c. Some comprehend the figure usually called *anticlimax* [CLIMAX] under the name Hysterology.

Hysterotomy (Gr. *ὕστερα*, *the womb*; *τέμνειν*, *to cut*). The extraction of the fetus from the uterus. The *Cæsarean operation*.

Hystrioides (Gr. *ὕστρις*, *a porcupine*). The name of the family of Rodent Quadrupeds, of which the porcupine (*Hystrix cristata*) is the type.

I

I. The ninth letter of the English and most European alphabets, represents two very different sounds in different languages. In the Greek language, the letter *i* is the simplest of the alphabetical characters, being represented by a single stroke, thus, *ι*. It is also susceptible of various interchanges, more particularly in the Latin, Greek, and French languages. When two *i*'s followed in succession, the Romans used to contract them into a single long *i*, as *Di* for *Dii*, *tibicen* for *tibiceni*; or made the

letter larger than usual, as *Chlus*. Shakspeare sometimes substitutes *I* for *ay* or *yes*.

Did your letters pierce the queen?

I, sir; she took 'em and read 'em in my presence.

According to Gebelin, the letter *i* in hieroglyphic writing represents the human hand. As a Roman numeral it denotes 1; and if placed before V or X, it diminishes by a unit the number expressed by these two letters. The form of *J* was originally identical with that of *I*; and it is only within the last century that

any distinction was made between them. In the English and French languages J has a sibilant sound, but the Germans pronounce it exactly as the English y before a vowel. In the Spanish language J represents a guttural, and is frequently substituted for X, which has the same sound.

I. H. S. This abbreviation is generally supposed to represent the initial letters of the words *Jesus Hominum Salvator*. More probably they are the first three letters of the Greek name $\text{IH}\Sigma\text{O}\Upsilon\text{X}$, *Jesus*.

Iacchus. [**BACCHUS**; **DIONYSUS**.]

Iambics (Gr. *ἰαμβος*). A species of verse used by the Greek and Latin poets, and especially by the Greek tragic poets. The derivation of the word has not been ascertained. The iambics of the Greek tragic poets consisted of three entire metres or six feet, and were thence styled the tragic *trimeter acatalectic*. They were composed originally, as their name implies, of a succession of iambi (—) [Foot, in Prosody]; but at a later period, various other feet were admitted, of which the subjoined table will convey an idea:—

1.	2.	3.	4.	5.	6.
— — —	— — —	— — —	— — —	— — —	— —
— — —	— — —	— — —	— — —	— — —	— —
— — —	— — —	— — —	— — —	— — —	— —

Hence it will be seen that a tribrach may be introduced into all the places except the last; a spondee in the first, third, and fifth places; a dactyl in the first and third places; and an anapest in the first. This foot may also be used in all other places of the verse except the last; with the general restriction, that in the third and fifth places it should be contained in a proper name, as *Antigōnē*, or in a preposition and the word which it governs; but two feet containing three syllables may not follow each other. The comic writers used much greater license in the iambic trimeter, admitting an anapest, even in common words, into every place but the last. For a full exposition of this and the other iambic metres employed by the Greek and Latin poets, the reader may consult Hermann's *Elementa Doctrinæ Metricæ*; Porson's editions of the *Tragedies of Euripides*; and the article 'Iambic Verse' in Rees's *Cyclopædia*. In most modern European languages, the verse of five iambic feet is a favourite metre. In French it is used almost entirely in lighter poetry, as by La Fontaine and similar writers, the heroic verse being the sixth foot, or alexandrine; but in English, German, and Italian, the former is the verse of ordinary use in serious composition. The Italians divide it into—1. The *verso cadente*, in which the line is decasyllabic, consisting of five iambi: e. g.

E come albero in nave al levò.—Dante.

This variety is very rarely admitted in serious composition, and is ill suited to the character of the language. Poets have, however, sometimes sportively attempted whole series of *versi cadenti*; as in the set of sonnets of Casti, called

I tre Giulii. 2. The *verso croico*, or hendecasyllabic, which is the ordinary one, ending in a short syllable:

Canto l'armi pietose, e 'l capitànò.

3. The *verso sdrucciolo*, which ends with two short syllables after the fifth iamb:

Passi oziosa, e di tu gloria immemòrò.

This also is rarely used in serious writing; but its occasional employment adds a peculiar grace to lighter poetry. In English, according to the genius of the language, the decasyllabic line is most common; the hendecasyllabic occasional, and more frequent in blank verse than in rhymes, in consequence of the comparative rarity of trochaic rhymes. The German language is rich both in iambic and trochaic terminations: consequently the decasyllabic and hendecasyllabic are more indiscriminately employed than in either English or Italian; and it is not uncommon to use the elegant variety of alternate iambic and trochaic rhymes, like the French masculine and feminine.

Iapetus (Gr. *Ἰαπετός*). In Astronomy, one of the satellites of SATURN [which see].

IAPETUS. In Greek Mythology, a Titan, brother of CRONOS and Hyperion, and father of PROMETHEUS.

Iatralēiptes (Gr. *ιατραιλεῖπτες*, from *ἰατρός*, a physician, and *ἀλείφω*, I anoint). A physician who cured diseases by external remedies only, as by friction, inunction, &c. There was among the Greeks a sect of *Iatralēiptes* founded by Prodicus.

Iatromathēmatikoi (Gr. *ιατρομαθηματικοί*). Physicians who explain the functions of the body, and the action of remedies, on mechanical principles. These doctrines seem to have originated with Asclepiades, and in modern times were promulgated by Borelli as founded on the atomic philosophy of Descartes.

Ibex (Lat.). This name is restricted to a species of goat; the *Capra Ibex* of Linnaeus, *Bouquetin* of Buffon and the French naturalists. It is characterised by having large horns, with a flattened anterior surface, and marked with prominent transverse ridges or knots. It inhabits the summits of the highest mountain chains in the continents of Europe, Africa, and Asia, but does not exist in the New World.

Ibis. A species of birds, belonging chiefly to the old genera *Scelopar* and *Tringa* of Linnaeus. The green ibis, *I. falcinellus*, is found in the warmer zones of all quarters of the world. In the Egyptian ibis, the prevailing colour is white, with long plumes of a p hue proceeding from the tertiary wing-fe. It was one of the sacred animals of the ancient Egyptians, the penalty for slaying which was death. (Herod. ii. 65.)

ICACINACEÆ (Icacina, one of the genera). A natural order of hypogynous Exogens, referred by Lindley to the Berberal alliance. They are related to *Oleaceæ*, and differ from that order in the calyx not enlarging with the fruit; in the stamens being alternate with the

ICARUS

petals; in the ovary being normally many-celled with axile placentation, and one-celled only by abortion; and in the ovules being suspended below the summit of the cell. They are not known to be of any special use.

Icarus. In Mythology. [DÆDALUS.]

Ice (Ger. eis). Frozen water. At the temperature of 32°, water, in its ordinary condition, crystallises into ice, which if slowly produced forms prisms crossing each other at angles of 60° and 120°; the primitive figure has not been ascertained, though it is probably rhomboidal. The arrangement of the acicular prisms in flakes of snow is very various, but in the same snow storm the same forms of arrangement generally prevail. The specific gravity of ice in its densest form is about .960. It is a non-conductor of electricity, and becomes electric by friction. The expansion of water in the act of freezing takes place with irresistible force, and the frequent rupture of thick iron and leaden pipes from this cause is a familiar instance of this. Exposed to air, ice loses considerably by evaporation. In the act of freezing, water parts with all soluble matter, so that coloured water becomes colourless ice; saline solutions become pure water; and spirituous liquors part with their alcohol. To effect this purification perfectly, the ice must be formed under circumstances which prevent the accumulation of blebs and air-bubbles, and the entanglement in the ice of any of the unfrozen or ejected liquor, for the foreign matters held previously in solution in the water are, in the act of freezing, transferred to the portion which remains unfrozen. If the whole of the water becomes a mass of porous ice, the impurities are retained in the pores; but if the freezing takes place slowly and regularly, time is given for the escape of the impurities, and thus the brilliant and perfectly transparent and dense masses of ice which we find in the Norway ice, as imported into this country, yield, when thawed, water almost equal in purity to that which has been distilled, and nearly free from air.

A remarkable property possessed by ice is that of *regelation*, first noticed by Professor Faraday. If two pieces of melting ice be placed together in a warm room, the film of water between them soon freezes and cements the two masses together, and this effect also takes place beneath the surface of warm water. It is thus that the broken masses of ice forming the ice cascade of a glacier, become again a solid and unbroken mass after the cascade is passed. [GLACIER.]

Ice Caves. [GLACIÈRES.]

Ice Islands. [ICEBERG.]

Ice Plant. The garden name of *Mesembryanthemum crystallinum*, whose leaves are covered with crystalline warts which look like fragments of ice.

Ice Spar. A mineralogical synonym for the Glassy Felspar which is found in Vesuvian lavas. The name, which has reference to the resemblance of the mineral to ice, is also

ICEBERG

applied to pellucid varieties of other kinds of Felspar.

Ice Trade. The progress of civilisation has rendered the means of procuring coolness in summer almost as indispensable as the generation of warmth in winter, and ice is now largely used for keeping small chambers called ice-safes at a low temperature, favourable for the preservation of provisions, whilst no inconsiderable quantity is directly applied to the cooling of wines and other beverages.

Prior to 1844, the consumption and use of foreign ice in England were very insignificant, but in that year the Wenham Lake Ice Company established their business in London, for the supply of pure ice only. This they procured from the Wenham Lake, about eighteen miles from Boston; but in consequence of the high freight, and the great waste attending its importation and storage, the speculation proved a failure. The company then turned their attention to Norway, from which ice of equal thickness and compactness could be obtained at less cost; the only difficulty being that of obtaining it of equal purity. The fjords of Norway yield ice of considerable thickness, in unlimited quantities, and of easy access for shipment; but such ice was found to be too impure for table use. The ice of many of the Scandinavian lakes, although very transparent, also proved, when analysed, very unsuitable, owing to the presence of much organic matter, which rendered it liable to putrefaction after melting. The lake ultimately selected by the company is remarkable for the purity of its water, which is attributable to the fact of its being supplied by springs only, and not by mountain torrents bringing down with them decomposing vegetable matter in large quantity. This lake, from which the company have procured their celebrated ice for many years past, lies a few miles from Dröbak in the Christiania Fjord, and being their property has been named and registered the *Wenham Lake*.

As soon as it became known that ice of great thickness could be obtained cheaply from the fjords and lakes adjoining the coast of Norway, fishermen began to use it in preference to English ice for packing and preserving their fish, thus creating an extensive demand for the inferior kind of block ice, the importation of which during the year 1864 exceeded 30,000 tons, brought chiefly to London, Hull, Grimsby, and Liverpool.

Iceberg (Ger. eis, and berg, a mountain).

A portion of a glacier broken away from some tract of land and floating in the sea. An iceberg is a true floating island; containing often an enormous quantity of stones, gravel, and mud, slowly accumulated, as the glacier is gradually pushed into the sea, until the smaller specific gravity of ice than water has made the mass in the sea so much lighter than the same volume of sea-water as to overcome the cohesion of the whole and cause a fracture. Masses of ice thus broken and floated off vary very much in dimensions, amounting sometimes to islands

ICELAND MOSS

measuring several miles in circumference, very high and of enormous depth.

Icebergs floating away from the land near the Arctic and Antarctic circles are conveyed by marine currents towards the equator, and often pass far into the temperate zone in both the northern and southern hemispheres. They have even been known to cross the Gulf Stream to the Azores, their depth being so much greater than that of the warm water crossing the Atlantic as to reach counter-currents, carrying them at right angles to that stream. From the south pole they have reached the Cape of Good Hope.

So great is the multitude of icebergs, that Dr. Scoresby, when navigating the polar seas in search of whales, counted 500 drifting along in latitudes 69° and 70° N. Some of them rose above the surface to the height of 100 to 200 feet, and measured from a few yards to a mile in circumference. (*Voyage in 1822*, p. 233.) Many were loaded with beds of earth and rocks, of such thickness that the weight was conjectured to be from 50,000 to 100,000 tons; and on closer examination the mass was found to be composed, among other substances, of granite, gneiss, mica-schist, clay-slate, granular felspar, and greenstone. Some idea may be formed of the immense depth to which icebergs descend, from the fact that the mass of ice below the level of the water is about eight times greater than that above. Icebergs differ from ice floes. The former are made up of ice collected in large masses on land and pushed into the sea till their bulk is very considerable. Ice floes are masses made up of flat ice, packed and heaped by driving winds and storms and opposing currents, and frozen together: in this way very large islands of ice accumulate; but they are not deep, and cannot therefore be floated so far, nor are they loaded with mud and stones.

Ice-land Moss. The *Cetraria islandica*, a common lichen in the mountainous districts of Europe. It contains a bitter principle, and a considerable quantity of starchy matter; it is tonic and nutritive, and is often prescribed in disorders of debility, and in pulmonary consumption.

Ice-land Spar. A transparent rhomboidal variety of Calcespar, or carbonate of lime, found in Iceland. This form of crystallised carbonate of lime is particularly valuable for experiments on the double refraction and polarisation of light. [CALCARBOUS SPAR.]

Ioh Dien (Ger. *I serve*). The motto of the prince of Wales, adopted originally by Edward the Black Prince in proof of his subjection to his father Edward III.; it has been continued without interruption down to the present time.

Ichneumon (Gr. *Ichneumon*, literally the tracker). A name applied in Zoology, in a double sense, to a Viverrine genus of quadrupeds, and to a family of Pupivorous Hymenoptera. As regards the Mammalia, the name is changed by Illiger for *Herpestes* [which see], and this term has been generally adopted by English zoologists. The ichneumon of the Nile (*Her-*

ICHTHYOLOGY

pestes Pharaonis) was one of the sacred animals of the ancient Egyptians; and although many fabulous feats were narrated of it as the enemy of the crocodile, there is no doubt but that the instinct which impels it to search for the eggs of the crocodile as an article of food tends materially to diminish the number of that destructive reptile. The ichneumon preys, however, on the eggs and young of various species of animals. Mr. Bennett relates that on one occasion a grey ichneumon (*Herpestes griseus*) killed no fewer than twelve full-grown rats, which were let loose to it in a room sixteen feet square, in less than a minute and a half. [PUPIVORA.]

Ichnography (Gr. *Ichnographia*, from *ichnos*, a mark or trace). In Architecture, the representation of the ground plot of a building. In Perspective, it is the representation of the building, intersected by a horizontal plane at its base or ground floor.

Ichor (Gr. *Ichôr*). A thin watery discharge. By the Greeks this name was applied to the divine fluid that issued from the wounds of the gods.

Ichorology (*Ichôr*, and *lôgos*). The anatomy of the lymphatic and secreting systems.

Ichthidin. An albuminoid substance contained in the roe of certain fishes.

Ichthyocella (Gr. *Ichthûs*, a fish, and *κόλλα*, glue). [ISINGLASS.]

Ichthyodorulites (Gr. *Ichthûs*, fish; *δôru*, spear; and *λίθος*, stone). The petrified spines of placoid fishes, of which they are often the sole evidences, especially in the Upper Silurian and Devonian strata.

Ichthyolite (Gr. *Ichthûs*, and *λίθος*). A name sometimes given to the fossil remains of fishes, without regard to their geological position. *Ichthyolites* have been found in rocks of all ages from the Silurian to the newest tertiary.

Ichthyology (Gr. *Ichthûs*, and *lôgos*). The science which treats of the nature, uses, and classification of fishes.

Fishes are those oviparous vertebrate animals which have a heart consisting of one auricle and one ventricle, which breathe water, and have the nasal cavity communicating with the external surface only. In a few species an air-bladder is present, and so organised as to act the part of a lung; but the principal, if not exclusive, organ of respiration consists, throughout the whole class, of branchiæ or gills. The gills are commonly composed of rows of slender flattened processes suspended by arches, attached in general to the hyoid bone, and covered with a membrane or tissue of innumerable minute and close-set blood-vessels. The water which the fish takes in by the mouth, instead of being swallowed, passes through the interspaces of the gills, and escapes by the fissures on each side of the head, called *gill-apertures*. The air contained in the water acts upon the blood, which is minutely subdivided in the branchial vessels; and the bilocular heart serves exclusively to propel the whole of the venous blood

ICHTHYOLOGY

to the branchial arteries, and is thus analogous in function to the pulmonary auricle and ventricle of the warm-blooded classes. The blood, having been decarbonised in the gills, is collected into the dorsal arterial trunk or aorta, and is propelled, without the influence of a systemic heart, to all parts of the body; whence it is again returned by the veins to the branchial auricle and ventricle.

The whole structure of a fish is as evidently adapted for swimming as that of a bird for flight. Being suspended in a fluid of nearly the same specific gravity as itself, it has no need of widely-expanded wings for its support. Many species, moreover, have the air-bladder so organised and developed as, by its contractions and dilatations, to vary the specific gravity of the fish, and aid in its ascent to the surface, or descent into the depths of the water. Ordinary progression is effected by the motions of the tail, which, by the action of powerful muscles, displaces the water alternately to the right and left; the gills, also, in expelling the water backwards, may contribute, by the reaction of the current, to propel the fish forward. The ordinary extremities, therefore, being of little use, are reduced to a low or rudimental condition; they are chiefly remarkable for the number of parts corresponding to the digital phalanges of the higher classes, and which, from their disposition, are called *rays*. The pieces analogous to the bones of the arms and legs are extremely shortened, and often quite concealed; the membrane supported by the diverging rays rudely represents the hands and feet. The members thus constructed are called *fins*; those which answer to the anterior extremities are called the *pectoral fins*; those which answer to the posterior extremities are the *ventral fins*. Other rays attached to peculiar bones above or between the extremities of the spinous processes support the vertical fins, which are mesial and single, either above the back, beneath the tail, or at the extremity of the tail. The upper vertical fin or fins are called the *dorsal*, the lower ones the *anal*, and the terminal one the *caudal fin*. The fin-rays are of two kinds. Some consist of a single bony piece, usually hard and pointed, sometimes flexible and elastic, and divided longitudinally; they are called *bony* or *spinous rays*: the others are composed of a vast number of little joints, generally branched at the extremity; they are called *soft*, *jointed*, or *branched rays*. In general the fins, which are placed in pairs, and correspond to the ordinary extremities, are four in number; but sometimes there are but two, and sometimes they are entirely wanting. When both pectoral and ventral fins are present, they may have the ordinary relative position; i.e. the pectoral fins may be considerably in advance of the ventrals—such fishes are said to be *abdominal*; or the ventrals may be placed below, or on the same or nearly the same transverse line as the pectorals—such fishes are termed *thoracic*; or the ventrals may be situated in advance of the pectorals, under the throat of the fish—when

the species are called *jugular fishes*. The vertebrae of fishes, when completely ossified, are united, with very few exceptions, by opposite concave surfaces. Most fishes have the body covered with scales. They are destitute of organs of prehension, except the teeth. The imperfection of the organ of touch is remedied in some by the development of soft tentacles or feelers.

The teeth are very various as to their number, form, and relative size. They are either anchylosed to the jaw-bones, attached to ligaments, or implanted in sockets; when the latter, the tooth has always a single and simple fang. The teeth may be placed on the maxillary, premaxillary, or lower jaw-bones: upon the vomer or sphenoid bones; upon the palatine or pterygoid bones, the tongue, the branchial arches, or the pharyngeal plates; or they may be entirely wanting.

Besides the branchial arches, the hyoid bone supports on each side a number of rays, which support the branchial or opercular membrane. This membrane is also generally further strengthened by three osseous plates called the *opercular*, *subopercular*, and *interopercular* bones: the kind of door thus formed is joined by the *preopercular* to the tympanic bone, and plays upon the *scapular arch*.

With respect to the subdivision of the class of fishes into orders, Cuvier, admitting the great difficulty which exists in defining them by fixed and easily appreciable characters, adopted after many attempts the following classification.

He first divided the class into two sub-classes:

Sub-class I. *Pisces ossei*, or fishes properly so called.

II. *Pisces cartilaginei*, or *Chondropterygians*, cartilaginous fishes.

The first sub-class are arranged according to the modifications of their organs of locomotion. All the osseous fishes which have the anterior part of the dorsal fin, or the first dorsal where there are two, supported by bony rays, with some bony rays in the anal fin, and at least one bony ray in each of the ventrals, are collected into an order, called *Acanthopterygians*.

All those osseous fishes in which, with the exception of the anterior dorsal and pectoral rays, all the rays are soft, constitute the order *Malacopterygians*.

The *Malacopterygii* are subdivided, according to the relative position or absence of the ventral fins, into *abdominal*, *jugular*, or *sub-brachial*, and *apodal* fishes.

Those fishes which have the branchiae in the form of tufts constitute the order of *Lophobranchii*.

Those fishes in which the maxillary and palatine arches are firmly united, or as it were soldered to the cranium, are called the *Plectognathi*.

The *Chondropterygian* fishes are divided into the three orders of:—

STURIONIANÆ,
SELACIANÆ, and
CYCLOSTOMES [which see]

The chief modification in the arrangement of the class of fishes has been the consequence of a study of the nature and affinities of the numerous extinct forms, and a comparison of these with existing species.

M. Agassiz has proved that certain species, which stand out as exceptions to the ordinary form and structure of the class among recent fishes, are the types of extensive orders which peopled the seas of the ancient world, and now characterise particular strata. This naturalist has likewise observed more closely than his predecessors the relations which subsist between the external scales and the internal structure; and he accordingly proposes to arrange the class of fishes according to the modifications of the scaly covering, and divides them into four orders, each of which contains fishes having a cartilaginous skeleton: and in each there are both Acanthopterygian and Malacopecterygian, Abdominal and Apodal genera. These orders are named *PLACODONTES*, *GANOSTOMES*, *CTENOIDES*, and *CYCLOIDES* [which see].

The discovery of intermediate forms, between the true fishes and the lower reptilia, e.g. *Lepidosiren* and *Archegosaurus*, has induced Prof. Owen to regard the groups Pisces and Reptilia no longer as separate classes, co-equal with the birds and mammalia, but to subordinate them as subclasses of the great group *HEMATOCRYA* or cold-blooded vertebrate animals [which see]. In that article is a list of the orders of fishes, with those of Reptilia.

Ichthyophagist (Gr. *ἰχθυόφάγος*). A fish-eater. Some savage tribes who live almost entirely on fish were called by the ancients *Ichthyophagi*.

Ichthyophthalmite (Gr. *ἰχθύς*, and *ὀφθαλμός*, the eye). A species of zeolite with a peculiar pearly lustre, resembling that of the eye of a fish.

Ichthyopterygia (Gr. *ἰχθύς*, and *πτερυγία*, a fin). An order of fossil reptiles in which the vertebral centra are ossified and biconcave; joined by syndesmosis, not by suture, to their neural arch. Pleurapophyses of the trunk long and bent, the anterior ones with bifurcate heads. Teeth with converging folds of cement at their base, implanted in a common alveolar groove, and confined to the maxillary, premaxillary, and premandibular bones. Premaxillaries much exceeding the maxillaries in size; orbit very large, a circle of sclerotic plates; nostrils near the orbits; limbs natatory, with more than five multi-articulate digits; an episternum and clavicles; no sacrum. The bones of the head, as in *Ganocephala*, include the supplementary postorbitals and supratemporals, and there is a foramen parietale, but there are small temporal and other vacuities between the cranial bones, a single convex occipital condyle, and one vomer which is edentulous. The order, which ranged from the lias to the chalk (excepting in the Wealden) inclusive, includes the genus *Ichthyosaurus*.

Ichthyosaurus (Gr. *ἰχθύς*, and *σαῦρος*, a lizard). A genus of extinct marine animals, which combined the characters of saurian reptiles and of fishes with some of the peculiarities of the Cetaceous Mammalia. The vertebrae of the backbone of the *Ichthyosaurus* resemble those of fishes in having their bodies joined by opposite concave surfaces; but the superior arches remain permanently detached, as in reptiles. The cranium resembles in structure that of the crocodiles, but is characterised by a peculiarly large orbit, in which a circular series of osseous sclerotic plates, analogous to those of the crocodile and birds, but relatively much larger, has been so frequently found as to prove it to be a generic structure. The nostrils are situated, not, as in the crocodile, near the point of the snout, but close to the anterior part of the orbit.

The teeth resemble in structure those of the crocodiles; but are lodged, as in some of the Lacertine Sauria, in a groove, and not in distinct sockets. The locomotive extremities are similar in construction to the paddles of the whale; but they are four instead of two in number, and the anterior paddles are connected by a broad coracoid, a complete clavicle, and a supplementary coracoid bone to a strong sternum; the flattened phalangeal bones supporting the fin are polygonal, and are relatively shorter and more numerous than in the whale tribe. The hind paddles are smaller than the fore, and are attached to a pelvis similar to that of the crocodile. Small supplemental bones are wedged into the lower part of the joint of the atlas and occiput, and a few of the succeeding vertebral joints; and the tail often presents a fracture at a particular point, whence the existence of a caudal fin has been inferred. From the form and position of masses of crushed and apparently half-digested fish bones and scales in the abdominal cavity of the *ichthyosaurus*, it is concluded that they preyed chiefly on fish; that they had a simple and capacious stomach, and an intestine provided with a spiral valve. The geological range of the *ichthyosaurus*, according to Dr. Buckland, began with the muschelkalk and extended through the whole of the oolitic period into the cretaceous formation. The most recent stratum in which any remains of this genus have yet been found is the chalk marl at Dover. The chief British depository of the bones of the *Ichthyosaurus* occurs in the lias at Lyme Regis in Dorsetshire.

Ichthyosis (Gr. *ἰχθύς*). A roughness and thickening of the skin, portions of which become hard and scaly, and occasionally cornuous, with a tendency to excrescences. Friction, warm baths, and occasionally stimulating ointments, have been of service in mitigating the progress of this disease; but it seldom yields permanently to any plan of treatment.

Ichthys (Gr. *ἰχθύς*, a fish). A word found on many seals, rings, urns, tombstones, &c., belonging to the early times of Christianity, and supposed to have a mystical meaning, from each

character forming an initial letter of the words Ἰησοῦς Χριστός, Θεοῦ Υἱός, Σωτήρ; i.e. Jesus Christ, the Son of God, the Saviour.

Icona (the name in Guiana). A tropical genus of *Amyridaceae*, consisting of large trees abounding in balsamic or resinous juice. The balsam obtained from many of the species is odoriferous, and is used as a perfume in South America. These balsams remain fluid for a considerable time, but ultimately harden, when they are used as incense. *I. heterophylla* yields Balsam of Acouchi, employed as a vulnerary; while that of *I. heptaphylla* is used as a remedy for dysentery, &c. The wood of *I. altissima* is preferred by the Indians for making canoes, and is called Cedarwood from its fragrance. It grows in the forests of Guiana to the height of one hundred feet or more.

Iconoclasts (Gr. εἰκών, an image, and κλάω, I break). Literally, breakers of images; a title applied to two of the Byzantine emperors, Leo the Isaurian and his son Constantine Capronymus, who during their reigns, which extended from 726 to 795, persevered in overthrowing the images in the Christian churches, and in extirpating their worship. The 338 bishops, also, who attended a council at Constantinople in the reign of the latter prince, and declared themselves in favour of his views, were stigmatised by the orthodox party under the same name. In the year 787, however, a general council was assembled at Nicea by the empress Irene, who inclined towards the old superstition, and the images were on this occasion restored to their former honours. This council, the second of Nicea, is the last respecting which the Greek and Latin churches coincide; the practice, however, of the Greek church makes a distinction between the use of pictures, which it allows, and graven images, which it studiously rejects. (Mosheim, *Ecc. Hist.*; Schlosser's *History of the Iconoclast Emperors*, Frankfurt 1812; Stanley's *Lectures on the Eastern Church*; Milman, *Latin Christianity*, book iv. chap. vii.)

Iconography (Gr. εἰκονογραφία). A term invented to designate literary works devoted to the description of monuments of art; and, in a more restricted meaning, of portraits. Among works on this subject, Didron's *Iconographie Chrétienne* may be specially mentioned. Iconology is the explanation of emblematic and allegorical representations.

Icosahedron (Gr. ἰκοσάεδρος). A solid figure bounded by twenty planes. One of the five Platonic bodies or regular polyhedra is an icosahedron. It has twenty equal faces, each of which is an equilateral triangle; it has thirty edges, and twelve solid angles, each formed by the meeting of five plane angles. The total surface of a regular icosahedron is 8·6802540 times the square on one of its edges, and its volume is 2·1816961 times that of the cube on one of its edges.

Icosandrous (Gr. εἰκοσι-, twenty, and ἀνδρ-,). Literally, any flower having twenty stamens or thereabouts; but it is usually con-

fined to those flowers in which these stamens are inserted into the calyx.

Icterus (Gr. ἰκτερος). The jaundice: so called from its resemblance to a bird of yellow colour, so named, but now unknown.

Ichneumon (Gr. ἰχνημὼν, a weasel). A genus of nocturnal carnivorous Mammals, intermediate between the Plantigrade and Viverrine Digitigrade tribes, having the plantigrade walk of the racoons and coatis, and the slender conical snout of the civets and other *Viverridae*. The dental formula of the genus is—

$$i. \frac{6}{6}; c. \frac{1-1}{1-1}; p. \frac{3-3}{2-2}; m. \frac{3-3}{3-3} = 38.$$

The teeth resemble those of the *Paradoxurus*, but are thicker and more tuberculous; and thus contribute, with the plantigrade structure of the foot, to indicate the affinity of the *Ichneumon* to the plantigrade *Ferae*. Three species are recorded; they are all natives of Southern Asia, and are called Benturong. The common Indian species (*I. albifrons*) is of the size of a domestic cat; but its body is longer and heavier, its legs shorter, and its gait lower and more crouching. The tail is extremely thick at its commencement, and gradually tapers to the extremity, where it curves upwards. The pupil of the eye contracts during daylight into a vertical fissure. A Benturong, which was kept in captivity many years, was fed on a mixed diet of animal and vegetable substances; and they most probably subsist on similar food in a state of nature.

Idea (Gr. ἰδέα). Literally, the image or resemblance of any object conceived by the mind. There is no word in any language the definition of which, from the obscurity of metaphysical writers, is attended with such difficulty as the term *idea*; and the difficulty is enhanced when we consider the vagueness with which its equivalents are expressed in different languages. Like many other terms of mental philosophy, the word *idea* is derived from the sense of sight, and in its most extended acceptation is employed to indicate 'every representation of outward objects through the senses, and whatever is the object of thought.' (Dugald Stewart's *Phil. Essays*, Appendix ii.; Kant's *Kritik der reinen Vernunft*; Ritter's *Geschichte der Philosophie*; Reid *On the Human Mind*; J. S. Mill, *Examination of Sir W. Hamilton's Philosophy*.)

Ideal (Gr. ἰδέα). In Painting and Sculpture, the ideal is an image formed in the mind, as the result of knowledge and experience, and based on the material or natural image. The *beau idéal* is an ideal beauty composed of a selection of beautiful parts, and put into harmony with each other by the skill of the artist. There can be no definite canon as to what constitutes the *beau idéal*, as each artist, according to his taste, skill, or experience, will imagine a different standard; thus the ideal of one school differs from the ideal of another, as much as complexion and temperament differ in the various races. Most great painters and sculptors have esta-

IDEALISM

blished their own ideal, and this has been delightful to others in proportion to the extent of the powers of the artist. Guido painted *Madonnas* and *Magdalens* from the head of his colour-grinder, his model constituting merely the basis of his ideal. Raphael, in a letter to Count Castiglione, very clearly states his recourse to an *ideal* standard in painting his *Madonnas*; he says, 'To paint a beautiful woman, I must see several; but as there are few beautiful women, I have recourse to a certain *ideal* in my mind. Whether this be beneficial to art, I know not; but I strive to form such an *ideal* in my mind.'

Zeuxis adopted the same principle, when employed by the citizens of Croton to paint a figure of Helen: he obtained five of the most beautiful virgins of the city as his models, and from each adopted what according to his ideal was most beautiful, and thus produced his famous picture. (Wornum, *Epochs of Painting*, 1864, pp. 37-329.)

Idealism. A term applied to several metaphysical systems, varying in its significance according to the meaning attached in each particular scheme to the word *idea*; from which it is derived. In England the best known system of idealism is that of Berkeley. In reference to this philosopher's doctrines, the word is used in its empirical sense for the object of consciousness in sensation. [PARACRITON.] In its Platonic or transcendental sense, the term *idealism* has been applied to the doctrines of Kant and Schelling; neither of whom is an idealist in the way in which Berkeley may be so called. The system of Berkeley may be thus expressed: The qualities of supposed objects cannot be perceived distinct from the mind that perceives them; and these qualities, it will be allowed, are all that we can know of such objects. If, therefore, there were external bodies, it is impossible we should ever know it; and if there were not, we should have exactly the same reason for believing there were as we have now. All, therefore, which really exists is spirit, or the thinking principle—ourselves, our fellow men, and God. What we call ideas are presented to us by God in a certain order of succession, which order of successive presentation is what we mean by the laws of nature.

Identigraphy (a word made up from Lat. *idem*, *the same*, and Gr. *γράφω*, *I write*). A name given by the Dutch periodicals in 1826 to an application of the art of lithography, by which a reprint of common letterpress printing is obtained in a short time, according to the inventor in two hours after the arrival of the mail. [ANASTATIC PRINTING.]

Identity, Personal. The sameness of the conscious subject, *I*, throughout all the various states of which it is the subject. The question, Wherein consists our identity, and what is its evidence? has been a source of manifold controversy to modern metaphysicians. By philosophers of the materialist school the doctrine has been ejected, as incompatible with daily and obvious experience. But indepen-

IDEOGRAPHIC CHARACTERS

dently of any hypothesis respecting the nature of the soul in itself, it has been argued, that as all our knowledge of a substance is derived from the qualities or phenomena which it presents to our senses, and that all we can mean by a substance being the same with itself is that it possesses the same qualities which it previously did (for if not, the substance is changed), so all we can know of the substance *mind* in particular is derived from observation of the changes which it undergoes. But we find that what we conceive to be the same individual does, at different periods, assume under the same circumstances widely varying appearances. A man will laugh at what when he was a child would have excited his anger or jealousy. This reasoning contains an evident fallacy. It does, in fact, like all other reasoning of the same kind, imply that very doctrine which it means to refute. Consciousness, it is asserted, is the joint effect of two substances acting one on the other. How, then, can we affirm that one of these substances is changed, unless by assuming that the other remains the same? How can we show that the phenomenon laughter in the man is different from the phenomenon jealousy or anger in the boy, unless we admit that we who observe these phenomena—i. e. by the premisses, on whom these phenomena produce a given effect—remain the same as we were when we were affected previously in a different manner. A lump of sugar, as we take it to be, no longer melts in what we take to be water. Assuming that the water remains water, we may fairly infer that the lump in question is *not* sugar, or vice versa; not so if we profess ourselves equally ignorant of the identity of both substances. This argument, it will be seen, applies equally to the materialist and non-materialist. Such may be said to be the *negative* evidence of our identity. Its positive evidence rests on the necessity and universality of its belief, as implied in every act of memory. To remember is to refer a past state of consciousness to the same subject which now at the present moment recalls it. (Bishop Butler's *Treatise on Personal Identity*; Brown's *Phil. of Human Mind*, Lect. 12, 13, 14, &c. &c.)

Identity, System of. In Philosophy (otherwise called *Identism*), a name which has been given to the metaphysical theory of the German writer Schelling. It rests on the principle that the two elements of thought, the objects respectively of understanding and reason, called by the various terms of *matter* and *spirit*, *objective* and *subjective*, *real* and *ideal*, &c., are only relatively opposed to one another as different forms of the one *absolute* or *infinite*; hence sometimes called the two *poles* of the absolute. [SCHELLING, PHILOSOPHY OF.]

Ideographic Characters (Gr. *ἰδέα*, and *γράφω*). In Philology, characters used in writing which express figures or notions, instead of the arbitrary signs of the alphabet. The Chinese characters are ideographic, al-

though the symbols, at first intended to represent distinct objects, have become by use merely conventional. The hieroglyphical characters of the ancient Egyptians were of the same description. Ideographical writing is opposed to phonetic. [PHONETIC; ALPHABET.]

Ideology (Gr. *idéa*, and *lógos*). Literally, the science of mind. The term applied by the later disciples of Condillac to the history and evolutions of human ideas, considered as so many successive modes of certain original or transformed sensations. The writings of this school are characterised by an unrivalled simplicity, boldness, and subtlety; and the different phases of its doctrines are admirably exhibited in the physiological researches of Cabanis, the moral dissertations of Garat and Volney, and the metaphysical disquisitions of Destutt de Tracy. (Damiron, *Hist. de Phil. en France*, &c. &c.)

Ides (Lat. *idus*). One of the three epochs or divisions of the ancient Roman month. The *calends* were the first days of the different months; the *ides*, days near the middle of the months; and the *nones*, the ninth day before the *ides*. In the months of March, May, July, and October, the *ides* fell on the 15th; in the other months on the 13th. The Romans used a very peculiar method of reckoning the days of the month. Instead of employing the ordinal numbers first, second, third, &c., they distinguished them by the number of days intervening between any given day and the next following of the three fixed divisions. For example, as there were always eight days between the *nones* and the *ides*, the day after the *nones* was called the eighth *before* the *ides*, the next the seventh *before* the *ides*, the next the sixth *before* the *ides*, and so on. In leap years, when February had twenty-nine days, the extra day was accounted for by calling both the twenty-fourth and twenty-fifth days of that month the sixth day *before* the *calends* of March; whence the leap year received the name *BISSEXTILIS* [which see].

Idiom (Gr. *ídíoma*, from *ídios*, peculiar). In Philology, a mode of speaking or writing foreign from the usages of universal grammar or the general laws of language, and restricted to the genius of some individual tongue. Thus, a sentence or phrase consisting of words arranged in a particular manner may be a Latin idiom; the same, arranged in a different manner, an English idiom, &c. The use of a particular inflexion of a word may also be an idiom. We also use the term *idiom* in a wider sense, to express the general character of a language. We have a number of subordinate words to express the idioms of particular tongues: thus, a Latin idiom is a Latinism, a French idiom a Gallicism, &c. The word *idiom* is also not uncommonly, but incorrectly, used in the same sense with the French *idiome*, a dialect or variety of language. *Idiotisme* is the French term expressing the correct signification of the English *idiom*.

Idiopathic (Gr. *ídios*, and *πάθος*, an affec-

tion). A disease which does not depend upon any other disease, and which is thus opposed to those diseases which are *symptomatic*.

Idiosyncrasy (Gr. *ídios*; σύν, with; and *κράσις*, a temperment). A state of constitution peculiarly susceptible of certain agents which in general produce no effect, or one perfectly different. Thus honey and coffee act with some few persons as violently aperient; very minute doses of antimony are occasionally followed by powerful emetic effects, and small quantities of mercury by salivation, &c.

Idiot (Gr. *ídíōtēs*, originally a private individual). In contemplation of Law, one who has been born totally deficient in understanding, or has lost it by sickness, so as to have no lucid intervals: lunatic, properly speaking, one who has lucid intervals. The care of idiots and lunatics is a branch of the prerogative of the crown, and exercised ordinarily by the chancellor. [LUNATIC.]

Idocrase (Gr. *ídios*, appearance, and *κράσις*, mixture, indicating that its forms are a mixture of those of certain other minerals). Volcanic Garnet. It is of various colours, and is sometimes called Volcanic Chrysolite or Hyacinth. It occurs in the ejected masses of Vesuvius, and elsewhere. It is an aluminosilicate of lime, with about 5 per cent. of oxide of iron.

Idol, Idolatry (Gr. *είδωλον*, *eidwolon*, from *είδωλον*, an image, and *λατρεία*, service). The figures of metal, stone, or wood, by which pagans for the most part represent their divinities are termed *idols*, and the worship paid to them *idolatry*. Although Grecian idolatry was dignified by all the charms which art could throw around it, it appears that the most popular idols were rude and almost formless images; traditional representations of the divinities, to many of which the vulgar notion attributed a divine origin, believing them to have fallen from heaven. Such were the Hermæ of Athens; the image of Artemis or Diana at Ephesus, mentioned in the Acts of the Apostles; the sacred *ancile*, or shield of the Romans: which seems to have commanded more of the veneration of the common people than the Pallas of the Parthenon or the Jupiter Olympius of Elis. (Vossius, *De Origine Idololatriæ*; Graves *On the Pentateuch*; Creuzer, *Symbolik der alten Völker*; Spence's *Polymetis*; Mém. de l'Acad. des Inscr. vol. xxxviii. Thirlwall, *History of Greece*, vol. i. ch. vi.)

Idrialine. A fusible inflammable substance, found by Dumas in a mineral from the quick-silver mines of Idria in Carniola.

Idryl. A fusible volatile hydrocarbon derived from Idrid coal by distillation.

Idyll (Gr. *είδύλλιον*, the diminutive of *είδος*, form). A short pastoral poem of which the object, or at least the necessary accompaniment, has been said to be a vivid and simple representation of ordinary objects in pastoral nature. It is in common usage the signification of this word is hardly different from that of eclogue. The pastoral poems of Theocritus are termed *Idylls*, those of Virgil *Eclogues*; but it would

IGASURIC ACID

be difficult to assign any distinction between the two, except that which arises from the greater simplicity of language and thought which characterises the former. Many critics, however, aver that the eclogue requires something of epic or dramatic action: the idyll only picturesque representation, sentiment or narrative. [ECLOGUE; BUOLIC.] In English poetry, among this class may be ranked, Shenstone's *Schoolmistress*, Burns' *Cottager's Saturday Night*, Goldsmith's *Deserted Village*, &c. &c. Mr. Tennyson's celebrated volume, *The Idylls of the King*, is in truth misnamed.

Igasuric Acid. A name given by Pelletier and Caventou to an acid which is found combined with strychnia in the *Nux vomica* and St. Ignatius's bean.

Iglite or Igloite. A variety of Aragonite found at Iglo in Hungary.

Ignatius's Bean. The seeds of a plant supposed to be the *Strychnos multiflora*, used in the Philippine Islands as a cathartic and emetic. [STRYCHNIA.]

Igneous Rocks (Lat. igneus, *fiery*). The materials poured out in a molten state from volcanoes [VOLCANO], or thrown out as ashes, lapillæ, or scoria, are beyond a doubt igneous rocks, and the large quantity of such materials that must exist, but is not poured forth, in the neighbourhood of volcanoes, is also of the same nature. Ancient lava exists, and is called *basalt*. But besides lava and basalt there are many varieties of igneous rock, which may, in many cases, be results of submarine eruption, the lighter matter, if any, erupted at the same time having been carried away and levelled by the action of water, and the point of eruption not being developed into a volcano. Many of the largest eruptions of lava have taken place at the sides of the cones, at a distance from the hill, whence smoke and gaseous products issue.

Igneous rocks are of all geological periods, but in proportion as they are more ancient they are the more likely to be obscure. Thus in the older rocks lava is no longer recognisable. Basalt there becomes greenstone, and is often so far metamorphosed as to simulate true porphyry. Volcanic ashes become regularly stratified, and difficult to distinguish from other mechanical rocks of similar mineral composition.

Igneous rocks are not to be confounded with hypogene or plutonic rocks, which have been also apparently formed with much heat and under enormous pressure, but which have not, so far as we can tell, been directly melted by heat, and were not erupted. The difference is very marked, and can generally be determined by microscopic examination of thin sections. The blebs or vesicles in the one are occupied by air or filled by crystalline minerals; those in the other are filled by water. The amount of pressure under which the rocks have been elaborated, induces differences so important that it is often difficult to identify similar minerals; but in fact the nature of the minerals formed

IGNITION

out of a given proportion of certain elements varies very greatly, and according to laws with which we are only now beginning to become acquainted.

Strictly and properly speaking, then, none are igneous rocks but those which we know to have existed in their last state in a molten form, so that lava, scoria, or the stony froth of lava, and ashes, or the fine dust of the scoria, can alone be named among modern rocks, and basalt and greenstone among the older. The greenstones, however, although sometimes certainly basaltic, are sometimes of doubtful origin. Porphyries of the more familiar kind, such as granite and syenite, are certainly not igneous in the proper sense, nor are the contents of veins in these rocks. All these are more properly METAMORPHIC [which see].

Ignis Fatuus (Lat. *vain* or *foolish fire*; a translation of the Fr. *feu follet*). A kind of luminous meteor, which is said to flit about in the air a little above the surface of the earth, and to appear chiefly in marshy places, or near stagnant waters, or in churchyards, during the nights of summer. Many instances are related of travellers having been decoyed by these lights into marshy places, where they perished; and hence the names *Jack-with-a-lantern*, *Will-with-a-wisp*: the people ascribing the appearance to the agency of evil spirits, who take this mode of alluring men to their destruction.

This somewhat dubious phenomenon has not yet received a satisfactory explanation. It cannot be referred to natural issues of spontaneously inflammable gas, since no natural production of such gas has ever been observed; neither can it be due to phosphorescence, for this kind of luminosity is too feeble to be seen at a distance. Divested of its imaginary attributes, the phenomenon may probably be referred to the issue of marsh-gas (light carburetted hydrogen) from the earth. This gas being ignited, either accidentally or intentionally, continues to burn with a flame invisible at a short distance in daylight, but sufficiently luminous to be well seen at night.

Ignition (Lat. *ignis*, *fire*). The act of setting fire to, or of taking fire; as opposed to combustion or burning, which is a consequence of ignition. The term *spontaneous ignition* is applied to cases in which substances take fire without previous application of heat: thus spongy platinum is said to become spontaneously ignited when introduced into a mixture of oxygen and hydrogen gases, and to cause their combustion. The particles of steel struck off by collision with flint become ignited on passing through the air, and falling upon gunpowder ignite it, and combustion ensues. Iron wire, when red hot, is also often said to be *ignited*, or in a state of ignition; and when in that state it is plunged into oxygen gas, or into chlorine, it undergoes combustion, and burns in those gases with the further extrication of heat and light.

The term *spontaneous ignition* is also ap-

IGNORAMUS

plied to cases of the accumulation of heat as a result of the oxidation or eremacausis of certain kinds of vegetable matter, so as to occasion them to burst into flame. [EREMACAUSIS.] Cotton, flax, tow, jute, and other such substances in a damp or in a greasy state are subject to this form of spontaneous ignition. The heaps of greasy cotton-waste used in wiping and cleaning machinery have in this way become the source of calamitous fires.

Ignoramus (Lat. *we are ignorant*). In Law, the endorsement of a grand jury on a bill of indictment, equivalent to *not found*. The jury are said to *ignore* a bill when they do not find the evidence such as to make good the presentment. The Latin form is now disused.

Iguana (Cuvier states, with reference to the derivation of this term, that it was originally a St. Domingo word, where it was pronounced by the natives *hiuana* or *igoana*, and quotes Hernandez and Scaliger as his authorities. He then proceeds to say that Bontius regards it as derived from the Japanese word *leguan*. In this case the Portuguese or Spaniards must have transported it to America, where they transformed it into *iguana*. They apply this term to the monitor as well as to the *iguana*. The *leguan* of Bontius is a monitor. The best authorities in herpetology have adopted the Latinised *iguana* as the generic name of the reptiles under consideration). A genus including certain large and beautiful lizards common in the tropical parts of America, some of which feed on vegetable substances, and are esteemed delicious food. The common iguana (*Iguana tuberculata*, Laur.) has accordingly received the specific names *delicatissima* and *sapidissima*. The generic name *igūana* is now restricted to those species which present the following characters: A large thin fold of skin or dewlap under the chin; cephalic cuticular plates, polygonal, unequal in diameter, flat or carinated; a double row of small palatal teeth; maxillary teeth, with their edges finely denticulated; a crest on the back and tail; toes long and unequal; a single row of femoral pores; tail very long, slender, compressed, covered with small, equal, imbricated carinated scales.

Iguanidae (from *Iguana*). The family of lizards, of which the genus *Iguana* is the type, and which is divided, according to minor modifications of the leading characters of the Iguanans, into the subgenera *Iguana* proper, *Corythophanes*, *Basiliscus*, *Aloponotus*, *Amblyrynchus*, *Metopoceros*, *Cyclura*, *Brachylophus*, *Enyalus*, and *Ophryosessa*.

Iguanines (from *Iguana*). The *Lézards iguaniens* of French herpetologists. This extensive tribe of Lacertine Sauria is divided by MM. Duméril and Bibron into two groups, *Pleurodontes* and *Acrodonites*.

The *Pleurodontes* include the families *Iguanidae*, *Polychridae*, *Anoliidae*, *Tropidolepididae*, and *Opluridae*.

The *Acrodonites* embrace the families *Galeotidae*, *Agamidae*, *Phrynocephalidae*, and *Stellionidae*.

IGUANODON

A short and thick tongue, with base not retractable in a sheath, and with the extremity free, mobile, and very slightly cleft, is the general character of this extensive tribe.

Iguanodon (from *Iguana*; and Gr. *ὄδους*, a tooth). An extinct genus of gigantic herbivorous reptiles, discovered by Dr. Mantell in the Wealden fresh-water formation of the South of England, in the localities of Tilgate Forest, Isle of Wight, and Purbeck. The chief distinctive character of this genus is the form of the teeth, which are denticulated along the margin of the crown, as in the *iguana*; but thicker, so as to present, when worn down, a broader grinding surface. The structure by which these teeth were adapted to the cropping of coarse and tough vegetable food, such as the *Clathraria* and similar fossil plants of the Wealden strata may be supposed to have afforded to the *iguanodon*, is thus described by Dr. Buckland: 'The teeth exhibit two kinds of provisions to maintain sharp edges along the cutting surface, from their first protrusion until they were worn down to the very stump. The first of these is a sharp and serrated edge, extending on each side downwards from the point to the broadest portion of the body of the tooth. The second provision is one of compensation for the gradual destruction of this serrated edge, by substituting a plate of thin enamel to maintain a cutting power in the anterior portion of the tooth until its entire substance was consumed in the service. Whilst the crown of the tooth was thus gradually diminishing above, a simultaneous absorption of the root went on below, caused by the pressure of a new tooth rising to replace the old one, until by this continual consumption at both extremities the middle portion of the older tooth was reduced to a hollow stump, which fell from the jaw to make room for a more efficient successor.' The anterior surface of the crown of the tooth also, instead of being flat and even, was traversed by alternate longitudinal ridges and furrows, the latter serving 'as ribs or buttresses to strengthen and prevent the enamel from scaling off, and forming, together with the furrows, an edge slightly wavy, and disposed in a series of minute gouges or fluted chisels; hence the tooth became an instrument of greater power to cut tough vegetables under the action of the jaw, than if the enamel had been a continuous straight line. By these contrivances also it continued effective during every stage through which it passed, from the serrated lancet point of the new tooth to its final consumption.

From the proportions which the bones of the *iguanodon* bear to those of the *iguana*, this extinct monster of a former world was thought to have been 70 feet in length from the snout to the end of the tail; the length of the tail alone being estimated at 50 feet; but recent discoveries have shown that the proportions of the trunk and tail were so modified as to reduce the total length of the animal to between 30 and 40 feet. The thigh-bone of the full-

ILEUM

sized *iguanodon* is twenty times the size of that of the *iguana*.

Ileum (Lat. *ile*, a gut, pl. *ilia*). The last portion of the small intestines, terminating at the valve of the cæcum.

Ilex (Lat.). The genus of the Holly, consisting of evergreen trees and shrubs, and a member of the order *Aquifoliales*. The Common Holly, *I. Aquifolium*, is well known, with its glossy spinous leaves and coral berries, as one of our principal Christmas decorations. Of this there are an immense number of varieties in cultivation, differing in the form, size, and colouring of the leaves, and in the colour of the berries. The plant has also a medicinal reputation, the root and bark being expectorant and diuretic, the leaves febrifugal, and the berries purgative and emetic. The wood is used for inlaying, and the inner bark to form bird-lime. *I. paraguayensis* is the Maté of South America. [MATÉ.]

Ilia (Lat.). The flanks, or the part of the abdomen which includes the small intestines. The *os ilium* is the haunch-bone, the upper part of the *os innominatum*, which supports the intestines.

Iliao Passion (Lat. *ilia*, the bowels). A vomiting of bilious and faecal matter in consequence of obstruction in the intestinal canal.

Ilíad (Gr. *Ílids*). This poem, which is generally regarded as narrating the events of the war of the Achæans against Troy, consists, in the form in which it has been transmitted to us, of twenty-four books, which are still thought by a few to make up one poem composed by a single poet. This position is maintained by Mr. Gladstone in his work on *Homer and the Homeric Age*. Mr. Grote, on the other hand, in his review of the Homeric controversy, allows the possibility of its composition by one author, but maintains that it consists of at least two poems pieced together. This conclusion is grounded chiefly on the fact that the first book professes to be the beginning of a poem which relates the wrath of Achilles and the consequent helplessness of the Achæans. But this book is followed by several others which exhibit the Achæan chieftains in the full tide of success, and as being wholly forgetful or careless of the absence of Achilles. So again the poet, who relates in the closing books how, by restoring Briseis and confessing his fault, Agamemnon wipes out the old grudge, has forgotten that the same confession has been made, and an equal humiliation undergone long before. Mr. Grote's dissection of the several parts of the poem may be found in his *History of Greece*, part i. ch. xxi. But it must further be remarked that the poem, as thus pieced together, relates only a few episodes in the last year of the war. Hector, indeed, is slain; but Ilion is not taken, and it is reserved for the *Odyssey* to relate incidentally how Achilles was slain at the western gates by the spear of Alexandros or Paris. The whole poem would thus appear to be part of a long series of legends, relating to the same subject. For the connection of these legends

ILLUMINATION, ART OF

with those of other Aryan nations, see MYTHOLOGY, COMPARATIVE. An analysis of the poems from nearly the same point of view as that of Mr. Gladstone is given in Mure's *Critical History of Greek Literature*, vol. i.; and in its solar aspect, in Cox's *Tales of Thebes and Argos*, pp. 63-85. [EPIC; HOMERIC POEMS.]

Ilia (Lat. *ilex*). A neutral crystalline body, contained in holly-leaves (*Ilex aquifolium*).

Illative Conversion. In Logic, that conversion in which the truth of the converse follows from the truth of the exposita, or proposition given. Thus the proposition, 'No virtuous man is a rebel,' becomes by illative conversion, 'No rebel is a virtuous man.' 'Some boasters are cowards;' therefore, & converso, 'Some cowards are boasters.'

Illecebraceæ (Illecebrum, one of the genera). A small natural order of hypogynous Exogens, belonging to the Silenial alliance, allied to *Portulacaceæ*, *Caryophyllaceæ*, and *Amaranthaceæ*, and distinguished by having both calyx and corolla present and symmetrical, the latter rudimentary, and by its scarious stipules and amphitropal ovules. They are plants of no importance.

Illicium (Lat. *illicio*, to allure). To this genus of Magnoliads belongs the Star Anise, *I. anisatum*, the fruit of which forms a considerable article of commerce amongst Asiatic nations. This plant derives its popular name from the stellate form and anise-like odour of its fruits, which are used as a condiment, and also for chewing for the purpose of sweetening the breath. The oil obtained from them is substituted for oil of anise. *I. religiosum* is held sacred by the Japanese, who decorate the tombs of deceased friends with it, and burn the fragrant bark as incense. The leaves, however, are said to be poisonous; and those of *I. floridanum* have the same reputation, whence the latter plant has acquired the name of Poison Bay. They are all evergreen shrubs or low trees, with laurel-like leaves.

Iluderate. A mineralogical synonym of *Epidote*.

Iluminati or The Enlightened. A secret society, formed in 1776, chiefly under the direction of Adam Weishaupt, professor of law at Ingolstadt in Bavaria. Its professed object was the attainment of a higher degree of virtue and morality than that reached in the ordinary course of society. It numbered at one time 2,000 members. It was suppressed by the Bavarian government in 1784. It has been supposed that this and some other secret societies were actively engaged in preparing the way for the French revolution; but of this no satisfactory proof has been adduced. (*Ency. von Ersch and Gruber*.)

Illuminating Power. [TELESCOPIC.]

Illumination, Art of. The practice of illuminating books with gold and colours seems to prevail generally in countries where printing is unknown, but where a written literature exists. With the introduction of printing it has invariably declined, if it has not altogether died out. In Arabia, Persia, &c., MSS. are

ILLUMINATION OF WIRES

still so ornamented; in Europe it may now be regarded simply as an amusement for persons with ample leisure at their command. But during the early and middle ages of the Christian era, the highest specimens of art are to be found in the pages of MSS. The monastic system, by cutting off large numbers from all secular business, gave great impulse to the art, especially in application to the office books of the church. Many of these books, containing exquisite miniatures and borderings of flowers or other designs, are preserved in libraries and museums, and are invaluable as throwing light on the development and history of art. The character of the illustrations, with the form of the letters, suffices to determine the age and country where the MS. was written; and a comparison of MSS. of Eastern and Western Europe brings before us the several stages which mark the growth of Christian iconography. (Didron, *Iconographie Chrétienne*.) The illuminated MSS. of historical works, as those of Froissart, Monstrelet, &c., are not less important, as illustrating the manners, costumes, and habits of life prevalent in the ages of which they treat. The devotion of the monastic illuminators to their work caused naturally a strong resistance to the introduction of printing, in which, however, books were for a long time prepared so as to resemble as closely as possible illuminated manuscripts.

Minute directions for the practice of this art, in which body colours are employed and the leaf-gold on size prepared in various ways, may be found in the curious work of Cennino da Colle, *De Arte Pingendi*. Imitations of illuminated works are now produced with more or less success by the process of printing; it is unnecessary to specify the many works so prepared by Messrs. Shaw, Owen Jones, Noel Humphreys, Pugin, &c.

Illumination of Wires. [MICROMETER.]

Illustration (Lat. *illustratio*). In Rhetoric, appears to differ from *comparison* or *simile* in this only, that the latter is used merely to give force to the expression; the former to throw light upon an argument. The term *illustration* is, however, sometimes used in a wider sense, in which it seems to comprehend *example*, which is the recital of a particular fact or instance evincing the truth of a general proposition laid down in the argument; and *parable*, which is a species of symbolical narrative, in which the actors and events are intended to represent certain other actors and events in a typical manner. [PARABLE.]

Illustrations. In Printing, the pictorial embellishments of a book, whether lithograph, copper-plate, or woodcut. The cheapest and, in some respects, the most effective are those on wood, worked in with the letterpress at one impression.

Ilmenite. A variety of Titaniferous Iron found crystallised and massive at Lake Ilmen, in Siberia: also in crystalline lamellar masses in the mica-schist of Glen Fannart in Argyllshire, Norway, &c.

IMAGINARY

Ilmenium. A metallic base, so called because its ore, *Ytthro-ilmenite*, is found near the Ilmen mountains in Siberia. Rose believes this metal to be identical with *niobium* or *columbium*.

Ivalite. A mineral found in *Elba*, in black prismatic crystals: it is a silicate of iron and lime.

Ilyanthus (Gr. *ἰλὺς*, mud, and *ἄνθος*, a flower). A genus of non-adherent Sea Anemones, with a proportionally larger column than in most true *Actinæ*.

Image (Lat. *imago*). A representation of the Deity in stone, wood, or metal. [IDOL.] For the principal events in the history of Christian image worship, see **ICONOCLASTS**.

IMAGE. In Optics, the spectrum or appearance of an object, made by reflection or refraction; or the *image* of an object may be more correctly defined as the locus of all the pencils of converging or diverging rays emanating from every point of the object, and received on a surface. It is by means of optical images that vision is effected. The eye is an assemblage of lenses which concentrate the rays emanating from each point of the object on a tissue of very delicate nerves called the *retina*, where an exact image or representation of the object is formed; and it is this image which is perceived or *felt* by the retina.

The images of external objects are painted on the retina in a reversed position, and from the retina the impressions are transmitted to the sensorium by the optical nerves. [EYE; OPTICS.]

IMAGE. In Rhetoric, a term somewhat loosely used; it appears generally to denote a metaphor dilated, and rendered a more complete picture by the assemblage of various ideas through which the same metaphor continues to run, yet not sufficiently expanded to form an allegory.

Imagery. May be defined as the generic term for *similes*, *allegories*, and *metaphors*, or such rhetorical figures as denote similitude or comparison.

Imaginary (Lat. *imaginarius*). In Algebra, a quantity is said to be imaginary when its symbolical expression involves the impossible operation of taking the square root of a negative quantity. The general form of such a quantity is $a + b\sqrt{-1}$, where a and b denote real magnitudes. By operating upon such quantities in the same manner as we do upon real ones, algebra gains, as it were, a double power. For instance, an equation of the form

$$a + b\sqrt{-1} = c + d\sqrt{-1}$$

involves the equalities $a=c$ and $b=d$. We find, too, that the intelligible, or rather the interpretable, results of algebraical operations are never vitiated by this mode of procedure, whilst uniformity in the enunciation of theorems and many other advantages are thereby secured. Thus, when we say that an equation has *always* a root, we mean that an expression of the form $a + b\sqrt{-1}$, where a and b are real (possibly 0), always exists which, substituted for x in that

equation and treated accordingly, will satisfy it identically. The imaginary or impossible character of symbolical expressions of the above kind, however, proceeds from the prescribed meanings attributed to the several symbols. The results of algebra, regarded as the science of the combination of symbols according to prescribed laws, are all equally real. If in accordance with these laws we attach a meaning to the symbols, the results in question will be true whenever they are intelligible, but they will not necessarily be always intelligible. Thus if, as in ordinary arithmetic, + and - denote simply the operations of addition and subtraction, and a and b represent numbers, $a - b$ will be imaginary or impossible whenever b exceeds a . On the other hand, if + and - denote progression in opposite directions on a straight line, $a - b$ will be perfectly intelligible whatever may be the relative magnitudes of the distances a and b . By recognising directly opposite directions, therefore, we escape certain anomalies, and found a more extended *single algebra*. In this system, however, $\sqrt{-1}$ would still remain without significance. Analogy suggests now the recognition of more than two directly opposite directions, and since $\sqrt{-1}$ denotes an operation which, twice repeated upon a magnitude (line) b , converts it into $-b$, we come to regard $b\sqrt{-1}$ as a line of the length b , turned from its initial position through a right angle, and by an obvious extension $a + b\sqrt{-1}$ then denotes the hypothenuse of a right-angled triangle, one of whose sides a has the initial direction, whilst the other, b , has a direction at right angles to the first. Thus arises a *double algebra* of a still more general character, and still more free from imaginary or impossible symbolical results. On this subject the reader may consult with advantage Peacock's 'Report on Certain Branches of Analysis,' in the *Transactions of the British Association*, 1834; De Morgan's *Trigonometry and Double Algebra*, London 1849; or the article 'Negative and Impossible Quantities,' in the *Penny Cyclopædia*.

The application of algebra to geometry naturally led to the application of the term *imaginary* to points, lines, &c., which cease to exist, actually, when the magnitudes or positions of certain elements of a figure are varied. Thus we speak of the *imaginary points* common to a line and a circle which do not intersect one another, meaning thereby the points whose coordinates would have the form $a + b\sqrt{-1}$, but would nevertheless satisfy, simultaneously, the equations of the circle and of the line. [CIRCULAR POINTS AT INFINITY.]

Imaginary Roots of an Equation. Expressions of the form $a + b\sqrt{-1}$, where a and b denote real numbers, which, when substituted for the unknown quantity x , and treated according to the ordinary laws of algebra, reduce the equation to an identity. [EQUATION.] If $a + b\sqrt{-1}$ is a root of an algebraical equation $F(x) = 0$ whose coefficients are all real, then the

conjugate expression $a - b\sqrt{-1}$ is also a root, and

$$(x - a - b\sqrt{-1})(x - a + b\sqrt{-1}) = (x - a)^2 + b^2,$$

which is necessarily positive for all values of x , is a factor of $F(x)$. Besides the ordinary arithmetical root, every number a has also imaginary roots which are found by multiplying the former by the imaginary Roots of UNITY.

Imagination (Lat. *imaginatio*). In Metaphysics, may be said, in its widest sense, to be synonymous with *invention*, denoting that faculty of the mind by which it either 'bodies forth the forms of things unknown,' or produces original thoughts or new combinations of ideas from materials stored up in the memory. While some (and among these Reid and Addison) limit the domain of this faculty so far as to teach that it is nothing more than a *lively conception* of the objects of sight, differing from conception only as a part from the whole; others, like Dugald Stewart, place it in the foremost rank of the mental faculties, attributing to its operation the origination and development of the sublimest and boldest thoughts in all the departments of human knowledge. Dr. Reid's chapter *On the Train of Thought in the Mind* gives a vivid though simple picture of the power of the imagination; while, at the same time, it illustrates the difficulty of treating this subject, owing to a want of precision in the definition of the term. In many philosophical disquisitions imagination is used as nearly synonymous with *fancy*. But it would seem that this is an erroneous application of the term; for, as Dugald Stewart observes, the latter should rather be considered as that peculiar habit of association which presents to our choice all the different materials that are subservient to the efforts of the former, and which may therefore be considered as forming its groundwork. [ASSOCIATION; POETRY.]

Imago (Lat.). In Entomology, the term applied to the state of the butterfly after it has emerged from the *pupa*.

Imaum or **Imân**. An inferior order of ministers of religion in the Turkish empire. The chief imaum of each mosque (Imam'ul-Haikh) performs the ordinary civil functions which in Europe have been in most countries assigned to parish priests, assisting at the circumcision, marriages, burials, &c. of his parishioners. He presides over the assembly of the faithful at the ordinary prayers; but the solemn noon prayer on Friday is under the superintendence of the Khatib, a higher minister (who is also called from that circumstance the *Imam'ul Djumâ*, or Friday Imân). The legitimate successor of Mahomet, who, in theory, is primarily an ecclesiastical chief, is termed *Imâm* by way of pre-eminence; but the Mussulmans are not agreed among themselves as to the character of this dignity, or as to those who have rightfully borne it. The Persians reckon twelve legitimate Imaums, of whom they believe the last (Mahadi) to be still living. (Taylor's *History of Mohammedanism*, ch. viii.)

IMBECILITY

Imbecility (Lat. imbecillitas, *weakness*). In Law, the state of a person who, although not positively non compos, or insane, is yet of such great weakness of mind as to be unable to guard himself against imposition, or to resist importunity or undue influence. (*Story's Equity Jurisprudence*.) Equity will not set a contract aside on the mere ground of imbecility; but its existence affords a material ingredient in examining whether it has been obtained fraudulently or by undue influence. The same principle prevails in the Civil Law, and in the Scottish and other systems founded on it. [LUNACY.]

Imbibition (Lat. imbibō, *I drink in*). The absorption of a liquid into the pores of a solid. Much importance has been attributed to this property as belonging to the organic tissues and as affecting their functions.

Imbricated (Lat. imbricatus, from imbrex, *a tile*). In Botany, a term used in speaking of the arrangement of bodies, to denote that their parts lie over each other in regular order like the tiles upon the roof of a house, as, for example, the scales upon the cup of some acorns: also applied in speaking of the saturation of petals or leaves, to denote that they overlap each other at the margin without any involution.

Embroglio (a word borrowed from the Italian brogliare, *to confound or mix together*; whence the French brouiller and English embroil). In Literary language, the plot of a romance or a drama, when much perplexed and complicated, is said to be an *embroglio*. The small burlesque theatrical pieces so termed by the Italians derive their ludicrous character from a similar species of absurdity.

Imides. Chemical compounds derived from ammonia by the replacement of two atoms of hydrogen by two of an organic radical. The basic imides being now generally termed *secondary amines*, the word is restricted to neutral derivatives.

Imitation (Lat. imitatio). In Music, a species of composition in which each part is made to imitate the others. Sometimes the motion or figure of the notes only is imitated, and frequently by a contrary motion, making what is called a *retrograde imitation*, or *imitations cancherzante*. Imitation is subject to less strict form and rule than fugue.

Immaculate Conception of the Blessed Virgin. In Theology, an opinion in the church of Rome, erected by the present Pope, Pius IX., into an article of faith. The festival of the Conception of Mary is of great antiquity in the Western Church: certainly as old as the eighth century. But the question, whether the mother of our Saviour was free from the taint of original sin, can hardly be traced as the subject of discussion before the affirmative was strongly maintained, in 1301, by the Franciscan Duns Scotus. Eighty years later, certain persons of the Dominican order maintained the contrary proposition; and thus a question, hitherto left in respectful mystery, became the subject of strong controversy between the two

IMMERSION

most powerful orders in the church. The combatants were popularly designated as Scotists and Thomists. In 1483, Sixtus IV. took upon himself to declare the doctrine of the Franciscans not heretical; and in 1494 the university of Paris, which had always adhered to the doctrine of Scotus, compelled a preacher who defended the Thomist side to retract. The council of Trent, when affirming the doctrine of original sin, declared that it did not intend to comprehend therein the instance of the Blessed Virgin. Still the question was not formally decided; and several successive pontiffs in the seventeenth century thought fit to renew their prohibitions against either side, treating the supporters of the opposite doctrine as heretical. Thus Clement XI., having made a constitution for the observance of the feast 'Conceptionis B.M. Immaculatæ,' was highly displeased that the words of his bull were printed in an Italian city, in 1709, in the form 'Festum Immaculatæ Conceptionis B.V.,' thereby perverting it into a testimony in favour of the Franciscan tenet. But with the revival of ultramontane views and high doctrines of Roman Catholic theology which has marked the present century, arose the desire to have this long-pending controversy terminated in the sense esteemed most honourable to the exalted personage who was the subject of it.

Immemorial (Lat. in, neg., and memoria, *memory*). In English Law, a custom or prescription is said to be immemorial, when its existence is presumable from a period anterior to possible proof. This in English law was long ago arbitrarily fixed at A.D. 1189 (the commencement of the reign of Richard I.). It is therefore deemed that a custom is established at law when reasonable affirmative evidence of its antiquity is shown, and no instance to the contrary is proved to have taken place since that year; but customs or prescriptions may now be established in some cases by evidence of user for a much shorter period. [PRESCRIPTION.]

Immersion (Lat. immersio, from immergo, *I plunge under*). In Astronomy, denotes the disappearance of any celestial object behind another or in its shadow. Thus in an eclipse of one of Jupiter's satellites, the immersion takes place when the satellite disappears behind the body of the planet, or enters into the planet's shadow; and in an occultation of a planet or fixed star by the moon, the immersion is the disappearance of the star or planet behind the body of the moon. In like manner, the reappearance of the body is called its *emersion*. The immersions and emersions of fixed stars occulted by the moon, are phenomena of great importance for correcting the lunar tables.

Immersion, Baptism by. Seems to have been the most ancient mode adopted in the Christian church. The *trine* immersion, in honour of the three Persons of the Divinity, is mentioned by Tertullian, and prescribed in the *Sacramentary* of Gregory the Great; but *single*

IMMOLATION

immersion was held valid by that pope, and his decision was confirmed by the fourth council of Toledo, A. D. 633.

Immolation (Lat. *immolatio*). A ceremony used in the Roman sacrifices, which consisted of throwing upon the head of the victim some sort of corn or frankincense, together with the *mola*, or salt cake, and a little wine.

Immortality. [SOUL.]

Immortelles (Fr.). The 'Everlasting flowers' produced by various Composite plants, of which *Holichrysum* may be taken as the type. They include *Antennaria*, *Gnaphalium*, *Aphelexis*, *Phanocoma*, *Waitzia*, *Helipterum*, *Rhodanthe*, &c. The so-called flowers are the flower-heads surrounded by dry scarious coloured involucre scales, to which their beauty is due.

Immunity (Lat. *immunitas*). In Jurisprudence, freedom from any legal obligation. Thus the phrase *ecclesiastical immunities* comprehends all that portion of the rights of the church, in different countries, which consists in the freedom of its members, or of its property, from burdens thrown by law on other classes.

Impact (Lat. *impactus*, part. of *impingo*, *I strike against*). In Mechanics, the instantaneous action of two bodies, one or both being in motion, at the moment of their collision. When the bodies have no motion of rotation, the impact is said to be *direct* or *oblique* according as the common normal to the surfaces of the bodies at their *point of impact* does or does not coincide with the directions of their previous motions. The impact of spherical bodies, elastic and non-elastic, is considered in all elementary treatises on Mechanics. [COLLISION.]

Impages (Lat.). In Architecture, the border or framework which surrounds the panel of a door.

Impalement (Lat. *palus*, a *stake*). A species of punishment still (though rarely) in use among the Turks, and known to some barbarous nations, which consisted in thrusting a stake through the body, and thus leaving the victim to a lingering death. It is of great antiquity, being referred to in the *Eumenides* of Æschylus.

IMPALEMENT. In Heraldry, the division of a shield palewise, when the shield is said to be *party per pale*. *Impalement per baron et feme* is the division which takes place on marriage; when the husband's coat is borne on the dexter side of the pale, and the wife's on the sinister. Formerly, the husband's and wife's arms were impaled by *dimidiation*; that is, the dexter half of the husband's coat was impaled with the sinister half of the wife's: and this inconvenient mode of marshalling was pursued in French heraldry down to the period of the Revolution.

Impanation (from Lat. *panis*, *bread*). In Theology, the substantial union of the body and blood of Christ with the elements of the eucharist without a *change* in their nature. The word appears to be first used in the controversy about the real presence in the eleventh century, and to be applied, by the supporters of transubstantia-

IMPEACHMENT

tion, to the less material doctrine of Berengarius and his followers. It has since been objected, by Roman Catholics, to the Lutheran theory, that it revived the old error of impanation. The supporters of the opinion of Berengarius were sometimes termed *Adessenarii*; from the word *adesse*, to be present.

Imparipinnate (Lat. *impar*, *odd*, and *pinnatus*, *winged*). In Botany, a term applied to pinnate leaves when there is a single terminal or odd leaflet, and not an even number of pairs.

Imparlanee (Fr. *parler*, to *speak*). A mode of delaying proceedings in a civil action by petition to the court for further time. General imparlanee was to the next term; special imparlanee to a specified day, which might be in the same term. The practice of imparlanee is now abolished (see stat. 2 Wm. IV. c. 39, and rule 31 of Trin. Term 1853), improved methods of procedure having been substituted.

Impastation. In Sculpture, the mixture of different matters bound together by means of cements capable of resisting the action of fire or air.

Impasto (Ital.). In Painting, a term applied to the substance or thickness of the colours as they are laid on the canvas; as thin, solid, heavy, &c.

Impatiens (Lat.). A very extensive genus of *Balsaminaceæ*, whose head-quarters are in India. One native species, *I. noli me tangere*, is called *Touch-me-not*, a name which alludes to a property possessed by the capsules of all the species, that of splitting up with elasticity into their component valves, if touched after they become ripe, the seeds being often scattered with violence: hence the generic name.

Impeachment (from the Latin *impetere*, to *prosecute*). A species of process against persons accused of treason, or high public crimes and misdemeanours of an inferior description. The first regular instances of this proceeding appear, according to Mr. Hatsell, on the rolls of parliament in the latter end of the reign of Edward III. Before that time the Lords seem to have exercised a high but irregular jurisdiction over state offences, at the prayer of the crown or of private persons. But in the case of Richard Lyon, 1376, we first find the Commons appearing in their public capacity as prosecutors: and several similar instances occur in the course of the following century. From the reign of Henry VI. to that of James I. impeachments seem to have fallen into disuse; bills of attainder, and prosecutions in the Star Chamber, having been employed in their stead. In the seventeenth year of James I. this form of proceeding was revived against Sir Giles Mompesson for having procured illegal patents, and from that time to the present has been the regular constitutional form of accusation for state offences. The form of the accusation exhibited by the Commons is styled the *articles of impeachment*. It is an undoubted right of the Commons to exhibit such articles against a peer for treason, or any

IMPENETRABILITY

other high crimes and misdemeanours; but it has been doubted whether the Lords have jurisdiction in capital cases over a commoner in this proceeding. In one instance (in 1681) they refused to act, but have in several other instances admitted their competency. Managers are appointed by the Commons to conduct the prosecution before the Lords. In case of an impeachment of a peer for treason, it is usual to address the crown to appoint a lord high steward; but the appointment of such an officer does not seem essential to the conduct of an impeachment. By 12 and 13 Wm. III. c. 2 it is enacted that a pardon under the great seal shall not be pleadable to an impeachment. This, however, does not deprive the king of his prerogative of pardoning after conviction. It was determined, on the impeachment of Warren Hastings, that this proceeding in the Lords is not put an end to by the prorogation or dissolution of parliament; and an Act was passed to prevent prorogation or dissolution from having the effect of putting a stop to the previous proceedings in the House of Commons. Judgment on impeachment must proceed on the same evidence which would be required in the ordinary courts of justice; in which respect this proceeding differs from that by bill of attainder.

Impenetrability (Lat. *impenetrabilis*, *not to be penetrated*). In Physics, one of the essential properties of matter or body. It is a property inferred from invariable experience, and resting on this incontrovertible fact, that no two bodies can occupy the same portion of space in the same instant of time. Impenetrability, as respects solid bodies, requires no proof; it is obvious to the touch. With regard to liquids, the property may be proved by very simple experiments. Let a vessel be filled to the brim with water, and a solid incapable of solution in water be plunged into it; a portion of the water will overflow exactly equal in bulk to the body immersed. If a cork be rammed hard into the neck of a phial full of water, the phial will burst, while its neck remains entire. The disposition of air to resist penetration may be illustrated in the following way: Let a tall glass vessel be nearly filled with water, on the surface of which a lighted taper is set to float. If over this glass a smaller cylindrical vessel, likewise of glass, be inverted and pressed downwards, the contained air maintaining its place, the internal body of the water will descend, while the rest will rise up at the sides, and the taper will continue to burn for some seconds, uncompassed by the whole mass of liquid. (Leslie's *Elements of Natural Philosophy*.)

Impennates, Impennies (Lat. *in*, and *penna*, a wing). The name of a tribe of swimming birds, having short wings covered with feathers resembling scales. The penguin (*Aptenodytes*) and the great Ark (*Alca impennis*) are examples of this group, which, however, is not a natural one.

Imperative Mood (Lat. *impero*, I com-

IMPETUS

mand). That form of the verb which denotes command, entreaty, or, in general, desire. [GRAMMAR.]

Imperator. [EMPEROR.]

Imperatorin. A neutral crystalline principle contained in the root of *Imperatoria Ostruthium*.

Imperfect Cadence. In Music. [CADENCE.]

Imperfect Concords. In Music, such as are liable to change from major to minor, or the contrary, as are thirds and sixths; still, however, not losing their consonancy.

Imperfect Number. A number which is not equal to the sum of its divisors. [PERFECT, ABUNDANT, and DEFICIENT NUMBER.]

Imperfect Tense. In Grammar, that modification of a verb which expresses that the action or event of which we speak was, at a certain time to which we refer, in an unfinished state. This in English is designated by the auxiliary 'was,' joined with what is called the *present participle* but is really the locative case of a participial noun. In Greek it is formed by prefixing the temporal augment ε to the root of the verb. This augment is supposed by Bopp to be the same as the negative particle α, which is here simply a denial of *present* time. In Latin this tense is formed, like the future, by adding an affix from the root *bhu*, or *bu* (Gr. *φύ*), to be.

Imperial (Lat. *imperialis*). In Architecture, a species of dome, whose profile is pointed towards the top, and widens towards the base, thus forming a curve of contrary flexure; the domes executed in Persia present the most striking illustrations of this system; in them the stability is owing entirely to the adhesion of the cement employed in their construction.

IMPERIAL. A beverage formed by dissolving two drachms of cream of tartar in a pint of boiling water, and flavouring it, when cold, with lemon peel and sugar.

Impersonal Verbs. In Grammar, those used only in the third person; as the Greek *ἔστι*, Latin *licet*, *it is lawful*. It is quite clear that every verb, whether active or passive, must have a necessary reference to some noun, either expressed or understood, for its nominative; and hence the doctrine of impersonal verbs has been justly rejected by the best grammarians, both ancient and modern. [GRAMMAR.]

Impetigo (Lat.). An eruption of small pustules, sometimes called the *moist tetter*. Something of this kind is often produced by particular trades, where irritating substances are applied to the skin. Cleanliness, cooling ointments, and occasionally the nitrated mercurial ointment much diluted, are useful. Harrogate water and baths have been recommended, and mild aperients. The eruption is not contagious.

Impetus (Lat. *force*). In Gunnery, the altitude through which a heavy body must fall to acquire a velocity equal to that with which the ball is discharged from the piece.

IMPETUS

IMPETUS. In Mechanics, the same with *momentum of force*.

Implication (Lat. *implicatio, an intanglement*). In Law, an inference necessarily arising from something declared. Thus contracts are said to be either express or implied. [CONTRACT.]

Implicit Function. [EXPLICIT FUNCTION.]

Impluvium (Lat.). In ancient Architecture, the outer part of the court of a house which was exposed to the weather. In the summer time, it was the custom of the Romans to stretch an awning over this part of their habitations.

Imponderable Substances. Heat, light, electricity, and magnetism are so called, by those who refer their phenomena to the presence of very subtle forms of matter of inappreciable weight.

Imports (Lat. *importo, I bring in*). The mass of commodities purchased from foreign countries, and employed either for manufacture, with a view to subsequent exportation and home use, or for immediate consumption, are called the *imports* of a country.

The declared value of each among thirty-two heads of imports, purchased by the United Kingdom in the year 1863, exceeded a million sterling. Of these quantities, the most valuable were cotton, reckoned at fifty-six millions; corn, including rice, at nearly twenty-nine millions; wool at nearly twelve millions; sugar at eleven millions and a half; tea at ten millions and a half; raw and thrown silk at nine millions and a half; timber at five millions and a half; coffee, wine, butter, and flax, each at about four millions and a half.

In ordinary years the largest amount (in value) of imports has been derived from the United States. Since 1861, however, British India has headed the list. Still the United States take the second place, France ranks next, then Egypt, China, Russia, the West India Islands, the North American colonies, Holland, Australia, the Hanse Towns, Prussia, Turkey, Belgium; the imports from each of these countries (stated in the order of the quantity supplied by each) exceeding five millions.

The following is the value of imports since 1854, the year in which the real value was first estimated:—

Year	£	Year	£
1854.	152,389,053.	1860.	210,530,873.
1855.	143,542,850.	1861.	217,485,024.
1856.	172,544,154.	1862.	225,716,976.
1857.	187,844,441.	1863.	248,980,942.
1858.	184,583,832.	1864.	267,375,333.
1859.	179,182,355.		

Imposing (Fr. *imposer*). In Printing, the arrangement of the pages of a sheet, or form, upon the imposing stone in their proper order, so that when they are printed and the sheet folded they will follow each other consecutively. The furniture is then put about them, with the

IMPRIMATUR

chase; and they are wedged up with quoins, so as to be ready for the pressman.*

Imposition of Hands. This ceremony is maintained in the English and other churches, as being conformable to the apostolic practice and that of the earliest ages, in which confirmation and the ordination of priests and deacons are supposed to have been accompanied with the performance of this ceremony. In Acts vi. the apostles are represented as laying their hands on those appointed to be deacons; in Acts viii. and xix. the converts who had been already baptised by Philip and John are in the same manner confirmed by Paul and the other apostles.

Impossible Quantity. In Algebra, the symbolical result of an impossible operation. The term is usually restricted to quantities expressible only in the form $a + b\sqrt{-1}$, where a and b denote real numbers. If—were the symbol of ordinary subtraction, however, and b denoted a greater number than a , the term *impossible* might, with equal propriety, be applied to the quantity $a - b$. [IMAGINARY.]

Impost (Lat. *impositus*, part. of *impono, I place upon*). In Architecture, the capital of a pier, or pilaster, that receives the thrust of an arch. The impost varies in the character of its mouldings with the order to which it is applied. Sometimes the whole of the entablature serves as an *impost* to an arch. The term is applicable to any supporting, or springing, piece.

The term *impost* is also frequently used as synonymous with a tax or public burden.

Imprecation (Lat. *imprecatio*). In Rhetoric and Poetry, a form of speech in which the superior powers are invoked to destroy or injure the objects of the speaker's enmity. In Shakespeare, Lear's imprecation against his daughters, and that of Timon against the Athenians, furnish noble instances.

Impregnation (Lat. *prægnans, pregnant*). In Botany, the act of the fertilisation of the ovules by means of the pollen tubes. It is equivalent to *fertilisation*.

Imprescriptible Rights. In Law, rights which cannot be lost to the owner through the claims of any other founded on PRESCRIPTION [which see].

Impressment. The forcible levying of mariners in time of war for the king's service at sea. The power of impressment is a branch of the king's prerogative. It is mentioned in the statute 2 Richard II. c. 4, as a recognised usage. Various classes of mariners are exempted from it by particular statutes. The officer impressing, acted under an impress warrant for that especial purpose; but the regularity of this instrument was carefully watched by the courts, and criminal informations have been also granted against officers guilty of unnecessary severity or acts of private malice in carrying it into execution. It was wholly disused in the Russian war of 1854.

Imprimatur (Lat. *let it be printed*). The term applied to the privilege which, in countries subjected to the censorship of the press,

IMPRINT

must be granted by a public functionary appointed for the purpose before any book can be printed. This formula was much used in English books printed in the sixteenth and seventeenth centuries, and was usually printed so as to face the title-page. This permission is still vested in some of our own universities, especially in Scotland, where it is not unusual to find on the title-page of some works recommended to public favour by the senatus academicus, the *imprimatur* of the principal. Unlicensed books and reprints were sometimes printed in places called by Moxon *holes*, or *holes private*.

Imprint (Fr. *imprimer*). The designation of the place where, by whom, and when a book is printed or published, always placed at the bottom of the title. Among the early printers it was inserted at the end of the book, and is styled the *colophon*. By the Act 39 Geo. III. c. 79, every printer was obliged to affix his name and residence to each article printed, and if it consisted of more than one leaf, then upon the first and last leaves, under a heavy penalty; but there were some exceptions. The Act 39 Geo. III. c. 79 was amended by 51 Geo. III. c. 65 and 2 & 3 Vict. c. 12. No prosecution can now be entered into for omitting an imprint without the consent of the law officers of the crown, and they will not interfere unless the work is of a violent political or treasonable character. But it has been recently decided in the superior courts that a printer cannot recover his charges unless his imprint appears on his work. The author, the printer, and the publisher of a libel are all liable to an action for damages, at the suit of the injured party, to an indictment, or in certain cases to a criminal information.

Impromptu (from the Latin phrase, in *promptu esse, to be in readiness*). In Literature, any short and pointed production, supposed to be brought forth on the spur of the moment; generally of an epigrammatic character.

Improper Fraction. In Arithmetic, one whose numerator exceeds its denominator: it consists of a whole number and a *proper fraction*. Thus the improper fraction $\frac{5}{4}$ is equal to $2 + \frac{1}{4}$, which latter, written in the form $2\frac{1}{4}$, is called a *mixed number*. In Algebra, a fraction whose numerator and denominator are rational functions of the same variable, is said to be proper or improper, according as the degree of the function in the denominator does or does not exceed that in the numerator.

Impropriation (Lat. *proprius, peculiar*). In Law, where the tithes, glebe, or other ecclesiastical dues of a parish are in the hands of a layman. The religious societies having, at the time of the Reformation, the property of many benefices in their hands, clauses were inserted in the acts by which they were dissolved to give that property absolutely to the king, by whom it was granted out to lay proprietors. In common language, such benefices are said to be *impropriated* as are in the hands of laymen; such as are held by

IN ANTIS

spiritual corporations, sole or aggregate, are termed *appropriated*.

Improvvisatore (from Lat. *improvisio, on a sudden, unexpectedly*). An Italian word, signifying a person who has the talent of composing and reciting verses on a given subject immediately and without premeditation. This peculiar talent, thus restricted, appears to belong, almost exclusively, to the Italian language and people. Much, no doubt, of the facility of these improvvisatori, which appears almost preternatural to one unaccustomed to hear them, arises from the peculiar ease and flexibility of their language, and its richness in rhymes. But this circumstance will not wholly account for so singular a national faculty; for, about the time of the revival of letters, Italy possessed improvvisatori in Latin as well as in Italian. Many poets have enjoyed considerable celebrity in their day from their success in this mode of composition; but we are not aware that any of their poems have acquired a permanent celebrity, although often taken down from their recitation. Tuscany and the Venetian States have been most famous for the production of improvvisatori, especially Sienna and Verona; in which latter city the talent seems to have been perpetuated by succession. The chevalier Bernardino Perfetti, the most famous of all these reciters, was of Sienna: he flourished in the first half of the seventeenth century. He is said to have possessed unbounded erudition, and to have been able to pour forth extempore poetical essays on the most abstruse questions of science. There have been many distinguished females possessed of this talent (*improvvisatrici*). Corilla, the most celebrated of them, was of Pistoja in Tuscany. She was the original of Madame de Staël's *Corinne*. She received in 1776 the laureate crown at Rome, an honour which had also been accorded to Perfetti. Germany is said to have produced one noted improvvisatrice, Anna Louisa Karsch. There appears no reason why the term *improvisation* should not also be applied to the delivery of unpremeditated discourses in prose. It is the exertion of a very similar faculty, perfected in the same manner by habit to a degree almost inconceivable by those not accustomed to witness its exercise. It is, however, much more general. The North American Indians are represented to possess it in a high degree. In Europe, it is most generally to be found in the pulpit. Public secular oratory of this unpremeditated description is far more common in England and the United States, and the power much more sedulously cultivated, than in the continental countries of Europe. (Forsyth's *Italy*; *Edinburgh Review* vol. xxii.; *Encyclopædia Metropolitana*.)

In Antis (Lat.). A building is said to be *in antis* when it has upon the façade two columns, detached, standing between two antæ that terminate the side walls of the building; as in the temples at Rhamnus and Sunium.

In Cæna Domini (Lat. *at the Lord's Supper*). The name of a celebrated papal bull, containing a collection of extracts from different constitutions of the popes, comprising those rights which, since the time of Gregory VII., have been uninterruptedly claimed by the Roman see, and a proclamation of anathema against all who violate them. It was annually read on Holy Thursday, whence it receives its name; but lately on Easter Monday. The sects of heretics are cursed in it by their several designations. A copy of the bull is hung up at the churches of St. Peter and St. John Lateran; and all patriarchs, primates, bishops, &c., are required to have it read once or more annually in their churches.

In Esse (Lat.). A term applied to things actually existing. A difference is made by authors between *in esse* and *in posse*: the latter being applied to things that are not, but may be; the former being said of things actually apparent and visible.

In Formâ Pauperis (Lat.). In Law, a person is said to sue as a pauper, or *in formâ pauperis*, when he takes advantage of the stat. 11 Hen. VII. c. 12, swearing himself not to be worth five pounds; in which case he is entitled to have any necessary writs or process gratis, and attorney and counsel assigned him without fee, and is excused from paying costs when plaintiff. By misconduct, and under certain other circumstances, the party is dispaupered, and loses his privilege. He is capable of recovering costs, although not liable.

Inarching. In Horticulture, grafting by approach, that is to say uniting a scion to a stock without severing its connection with the parent until it has become united to the stock; the branches being brought together in an arching manner.

Inauguration (Lat. *inauguratio*). This term was originally applied to the Roman ceremony by which the augurs consecrated any person or thing to the service of the gods: it is now improperly used in a sense nearly synonymous with the consecration of a prelate, or the coronation of a king or emperor, and is even employed to denote an introduction to any office with certain ceremonies, or the commencement of any undertaking.

Inca or Ynca. A name given by the Indians of ancient Peru to their kings and princes of the blood. The empire of the Incas, founded, according to tradition, by Manco Capac, extended over the table-land of the Andes, from Pasto to the neighbourhood of Chili, as well as the lowlands on the coast. It was destroyed by the Spaniards under Pizarro and Almagro. The blood royal of the Incas is preserved, or believed to be so, among the Indians of the present day; and Tupac Amaru, who carried on a long and nearly successful insurrection against Spain in the latter part of the last century, professed to be descended from them.

Incandescence (Lat. *in, and candere, to be warm*). The luminosity exhibited by a substance when heated up to a certain point.

Incantation (Lat. *incantatio*, from *in*, and *canto, I sing*). A form of words combined with certain ceremonies for superstitious purposes. They were most commonly resorted to by unsuccessful lovers. [PAULTRON.]

Incarceration (Lat. *in, and carcer, a prison*). Literally, imprisonment. In Surgery, this term is generally applied to ruptures or hernia, with the same meaning as *strangulation*; but, according to Scarpa, an *incarcerated* hernia is that in which the course of the intestinal matter is interrupted without any considerable injury of the bowel itself; whereas in *strangulated* hernia the vitality of the bowel is affected, or there is organic injury of its coats. The functions of the merely incarcerated intestine are healthily resumed upon its return into the abdomen, which is not the case where true strangulation has taken place.

Incarnation (Lat. *caro, carnis, flesh*). A word in common use among theologians to express the union of the Godhead with the Manhood in Jesus Christ. For the opinions of the Arians, Eutychians, Nestorians, Sabellians, and Socinians on this subject, see the respective articles.

Incendiary (Lat. *incendiarius*, from *incendo, I burn*). Literally, one who sets fire wilfully to a building or stores; but it is used also in a metaphorical sense for any political agitator who seeks to inflame the minds of the people. [ARSON.]

Incendiary Letter. In Law, a common, though not strictly a legal phrase, especially in Scotland, for threatening letters, meaning not only the burning of property, but murder or other mischiefs.

Incense. [FRANKINCENSE.]

Incense-tree or Incense-wood. Names implying the use to which the resinous wood and juice of some species of *Iceia*, especially *I. guianensis* and *I. heterophylla*, are applied.

Inceptive (Lat. *incipio, I begin*). A word used by Dr. Wallis to express such *moments* or first principles as, though possessed of no magnitude themselves, have yet the power of producing it by being extended or enlarged. Thus a point or a line, though the former has no proper magnitude and the latter no breadth, are both said to be *inceptive* of enlargement.

In the Latin language *inceptive* or *inchoative* verbs (the latter term being derived from the Lat. *inchoare, to begin*) are those which, according to grammarians, are characterised by the termination *scō* or *scor* added to their primitives, to express the augmentation of the qualities indicated by the words from which they are derived: as *augere*, to increase; *augescere*, to begin to increase; *pallere*, to be pale; *palescere*, to grow pale.

Incertum Opus (Lat. *uncertain work*).

INCH

In ancient Architecture, a species of walling whose face exhibits an irregularly formed masonry not laid in horizontal courses, or in regular dimensions.

Inch. A measure of length; the twelfth part of a foot.

INCH. A word used as a prefix to certain small Scottish islands, as Inch-Keith, Inch-Garvie. It is derived from the old Irish or Gaelic word *INIS* [which see].

Incidence (Lat. *incido*, *I fall upon*). The meeting of one body with another. The term *angle of incidence* is used by writers on Mechanics and Optics in different senses. Thus, in the case of a body striking against a plane, the angle of incidence is by some understood to signify the angle formed by the line in which the body moved with a straight line perpendicular to the plane; while others use the term to denote the angle which the line of incidence makes with the plane itself. When light or any elastic body is reflected from a surface, the angle of incidence is equal to the angle of reflection; and in the case of refraction, the sine of the angle of incidence has to the sine of the angle of refraction a constant ratio for the same media.

Incident. In Law, something necessarily appertaining to and depending on another, which is termed the *principal*.

Incineration (Lat. *in*, and *cinis*, cineres, *ashes*). The combustion of organic substances for the purpose of obtaining their ashes or incombustible residue.

Incisors (Lat. *incido*, *I cut*). The teeth implanted in the premaxillary bones of the upper jaw and in the corresponding place in the lower jaw, and generally shaped for the purpose of cutting or coarsely dividing the food.

Inclination (Lat. *inclinatio*). A term of frequent occurrence in Geometry and Physics. Euclid makes use of the term in order to define an angle; a more satisfactory way, perhaps, would be the precisely opposite one of regarding inclination as synonymous with angle, the latter being defined as a *quantity of turning or rotation*. [ANGLR.]

INCLINATION. In Astronomy, the planes in which the planets revolve round the sun are *inclined* at different angles to the plane of the ecliptic. Again, the axes of rotation of the planets are *inclined* to the planes in which they revolve. The measure of these angles is called the *inclination*.

Inclined Plane. One of the five simple mechanical powers. The theory of the inclined plane is at once deduced from the decomposition of forces. The weight of a body resting on such a plane, the pressure which it exerts, perpendicularly, on the plane, and the force which must be applied parallel to the plane in order to prevent its descent, are respectively proportional to the length, the base, and the height of the plane.

There are two properties connected with the motion of bodies on inclined planes which

INCLOSURE

may be here noticed. The first is, that the velocity acquired by a body in descending from any altitude to a horizontal plane is the same when it reaches the horizontal plane, whether it has been allowed to fall freely in the vertical, or been constrained to move along an inclined plane at any angle of elevation. The second is, that the times of descent through all chords of the same circle to the lowest point are equal, and equal to the time which the body would take to fall through a height equal to the diameter of the circle. Thus, let A B be the diameter, and C B, D B, and E B chords of a circle; the time which a heavy body would require to fall vertically through the diameter is the same as that which it would require to roll down the inclined plane C B, or D B, or E B. In other words, bodies placed at A, C, D, and E, and abandoned at the same instant to the action of gravity, would arrive at B at the same time. In these propositions it is supposed, of course, that there is no resistance from friction.

Inclinometer. An apparatus for determining the vertical element of the magnetic force. The difficulty of determining this element by a direct method is considerable, on account of the delicacy of the apparatus which is requisite. Various indirect methods have been proposed. Dr. Lloyd, in the *Account of the Magnetical Observatory at Dublin*, describes an Inductive Inclinometer, 'the principle of which is the measurement of the intensity induced on a vertical bar of soft iron by the deviation it is capable of causing in a horizontal bar suspended near it.' Weber, of Göttingen, proposed a method, in which 'the deflection of the horizontal magnet is produced by the earth's magnetism, induced not on a vertical bar of soft iron at rest, but on a ring, sphere, or plate of copper made to revolve about a vertical axis.' Dr. Lamont, of Munich, proposed a third and less simple method: 'As in Dr. Lloyd's process, a bar of soft iron is used as a temporary magnet. The bar so temporarily magnetised is made to act unequally on the two bars of an astatic magnetic couple, thereby tending to draw them aside from a given position in which they would otherwise be held by a fixed magnet of a given power. This tendency is, however, destroyed by another magnet placed in a given position at a given distance. A series of reversals and changes of distance in the soft iron bar and the neutralising bar is then operated, which furnishes equations by means of which every quantity excepting the intensity sought and known quantities can be eliminated.' (*British Association Report*, 1842.) [MAGNETOMETER.]

Inclosure (Lat. *includeo*, *I shut up*). This term, in a general sense, is one of the first acts of appropriation, since in a new country when any portion of land is purchased, or taken possession of, it is inclosed; that is, surrounded by a boundary line, indicated by certain ob-

INCLUSA

jects, natural or artificial, or of both kinds. In a particular sense, to inclose land is to divide it into fields, and surround these by fences, in order that each field may be devoted to a particular description of culture. If nothing further than the cultivation of plants of different kinds were carried on in the fields of a farm, their subdivision by fences would be altogether unnecessary; but as in most cases fields are kept alternately under tillage and pasture, it is desirable to have fences to confine the pasturing animals to the field appropriated for their use.

In Law, the inclosure of common or waste land, on which the rights of commoners subsist, is effected in England through Acts of Parliament, either special or general, by the instrumentality of commissioners appointed under those Acts. The last general inclosure Act is 8 & 9 Vict. c. 118, amended by subsequent Acts.

Inclosa (Lat. *inclusus*, part. of *include*, *I inclose*). The name of a tribe of shell-bearing Acephalous Molluscs in the system of Cuvier, characterised by the closed state of the mantle, which everywhere surrounds and envelopes the body, leaving only a narrow aperture for the passage of the foot, and being prolonged posteriorly into two siphons projecting beyond the shell, which is always open at its two extremities. The bivalves of this family are remarkable for their powers of burrowing and excavating clay, sand, wood, or even stony rocks; and many of the genera secrete, in addition to the ordinary valves, a calcareous lining to their burrows, which forms a tube surrounding the valves themselves. The relative proportions of the tube and valves well illustrate the so-called law of the *balance of organs*, the valves becoming diminished in size as the external sheath is more developed. In the ship-borer (*Teredo navalis*), which has the longest tube, the valves are of the smallest size, being reduced to the office of mere boring instruments, instead of serving to protect the soft parts of the animal. In the watering-pot shell (*Aspergillum*, Lam.) they cease to be movable organs, and are blended or confluent with the external tube; this is dilated at the anterior extremity, which is surrounded with a projecting radiated ridge, and closed by a convex plate perforated like the mouth of a watering-pot.

Inclusi or Reclusi (Lat. *shut up*). In Ecclesiastical History, a class of religious persons who lived as hermits in single cells, generally attached to monasteries, sometimes in the neighbourhood of villages and towns, under the law of not leaving them unless in case of extreme necessity and with the approbation of the bishop, whose seal, or that of the abbot, was impressed on its door. The cells are said to have been commonly twelve feet in length and breadth. Nuns became sometimes, but more rarely, recluses.

Incognito (Ital. *unknown*). This word, abbreviated into *incog.*, denotes the disguise resorted to by the great when they are un-

INCOME

willing to be recognised. It consists either in assuming a different name or title for the moment, or in travelling from one place to another without a retinue or other marks of distinction.

Incombustible Cloth (Lat. *combustio*, a burning). This term was originally applied to cloth with which asbestos was interwoven; on burning away the fibres, the incombustible mineral texture remained.

More recently, cloth and other materials have been rendered to a great extent incombustible by impregnating them with certain saline substances, which, upon the application of fire, form a species of glass upon the goods, and prevent them burning with flame by protecting them from the necessary access of air. [COMBUSTION.] Borax, alum, and phosphate of soda, or ammonia are the most effectual salts for this purpose; and by properly applying them, with starch, if to muslin dresses, curtains, or bed furniture, or with size to paper hangings and scenery, these several articles may be rendered incapable of burning with flame, and thus serious accidents by fire prevented. Wood may also be rendered comparatively incombustible, by soaking it in solutions of the above salts. [ASBESTUS.]

Income. In Finance, the annual produce of taxation and other sources of public revenue, the object of which is to defray the charges of administration, of defence, of justice, and of public credit.

Some of the annual charges to which the nation is liable, are fixed, as, for example, the interest on the funded debt, the civil list, and some few similar liabilities. Others are variable, as the charge of the army and navy, and the interest on the floating debt. On the latter subjects votes in detail are taken every year, and, when parliament is pledged to supply, the administration, through the Chancellor of the Exchequer, announces its budget of taxes for the forthcoming financial year. Unless something unforeseen occurs, the precision with which the Chancellor of the Exchequer anticipates the revenue derivable from the taxes imposed, is the measure of that official's intelligence and capacity. In general it is the practice to include a slight estimated surplus in the aggregate of the year's taxation. All excess of income over expenditure is devoted to the extinction of a part of the public debt.

In the following table it will be observed that the charge of collecting the revenue is not included in the first eight years, but is so included afterwards. It should be remembered, also, that in all inferences from public expenditure in the United Kingdom as contrasted with that of other countries, a large and variable amount of taxation for poor rates, county rates, &c. is not included in the general account of public charges, though analogous taxation does exist and is included generally in the fiscal arrangements of continental countries.

INCOME

Total Amount of the Estimated and Actual Revenue and Expenditure of the United Kingdom, with the Difference between the Estimated and Actual Amounts, and the Surplus or Deficiency of Income.

(In this Table, in accordance with the system upon which the Budget Estimates have been framed, the years ended April 5 are given from 1849 to 1854, and the figures for the Revenue and Expenditure show the Net amounts up to the year ended March 31, 1856, and the Gross amounts after that Period.)

Years ended	REVENUE			EXPENDITURE			Surplus (+) or Deficiency (-) of Income	Years ended
	Estimated to the Budgets	Actual Receipts at the Exchequer	More (+) or less (-) than Budget	Estimated in the Budgets	Actual Payments out of the Exchequer	More (+) or less (-) than Budget		
NET AMOUNTS.								
(Exclusive of Charges for Collection of Revenue, &c.)								
April 5, 1849	£2,130,000	£3,017,738	+ 887,738	£4,161,256	£3,287,111	- 874,145	- 269,378	April 5, 1849

* 1858-64.—Excluding 1,000,000*l.* to pay off Ways and Means Bills issued in 1854-5.

† 1859-60.—Including 858,557*l.* for Operations in China, not provided for in the Budget Estimate.

‡ Exclusive of Expenditure for Fortifications, provided for by creation of Annuities, and not estimated in the Budgets.

§ 1861-62.—Exclusive of a Supplementary Estimate presented in 1862 on account of the Expedition to Canada.

¶ 1862-63.—After deducting 140,000*l.* for the drawback upon Hops.

⌘ Including 585,000*l.* of Supplementary Estimates.

INCOME. In Political Economy, the aggregate value of all material products derived from the labour of a nation in any one year, constitutes its income, after deductions for the replacement of such capital as is expended in the process of production.

Many calculations have been made as to the amount of national income, but most of these err in the fact that they are estimated from such personal incomes as form the object of direct taxation, added to those which fall below it. But it will be clear that all personal income which is derived without the expenditure of labour on the part of the recipient, is in effect, values being consequent on labour only, a deduction from the fruits of labour itself, or from the capacity of expenditure which the labourer would otherwise possess. The rent of land, the dividends on public debt, interest paid by private individuals on loan or mortgage, with all payments made for administration, protection and instruction, and all taxes which are imposed on the public for other purposes, are not to be reckoned in national income along with the products of labour, but are only suggestive of what that income is. In other words, the aggregate of private incomes is largely in excess of the amount of national income, because a large portion of every private

income is charged with the maintenance of other private incomes. The service rendered by the recipients of such incomes may be of the highest importance, both to the community at large and to parties who make the payments; but they must be in the estimate of gross income looked on as part of the expense of the process of production, or the same value will be reckoned twice or even many times over in the calculation.

INCOME-TAX. [TAXATION.]

Incommensurable (Lat. in, neg., con-
cum, *with*, and mensurabilis, *measurable*). Two or more quantities of the same kind are said to be incommensurable when no other like quantity is exactly contained in both. Two incommensurable quantities, therefore, can never be proportional to two numbers or even to two fractions; since the latter, after reduction to a common denominator, are proportional to their numerators, and any two numbers whatever have unity for their common measure. Hence arises the necessarily imperfect character of all algebraical demonstrations of geometrical theorems involving the proportionality of lines, areas, or volumes, and hence also the need of Euclid's fifth and perhaps most perfect book. Two lines chosen at random will in *general* be incommensurable, in other words the probability of

INCOMPATIBLES

their being commensurable is exceedingly small; and in attempting to represent these lines by numbers, the utmost we can do is to assign two numbers which shall be *as nearly as we please* proportional to the lines. The diagonal and side of a square, for instance, cannot be exactly represented by any two numbers whatever; for, as Euclid has proved in his tenth book, they are incommensurable.

In fact, if ABC be half a square, CC_1 a circular arc described around A as centre, and C_1A_1 a tangent to this arc at C_1 , it can easily be shown that $BC_1 = C_1A_1 = A_1C$, so that A_1BC_1 is itself half a smaller square. Now if AB and AC had a common measure, the latter would also be a common measure of $BC = AC$ and of $BC_1 = AB - BC$, and hence also a common measure of B_1C_1 and $A_1B = BC - B_1C_1$. [COMMENSURABLE.] Hence the diagonal and side of the first square can have no common measure which is not also a common measure of the diagonal and side of the smaller square, as well as of the diagonal and side of a third and still smaller square obtained from the second in the same manner as the second was obtained from the first; and so on. The construction being manifestly endless, we conclude that the diagonal and side of the original square can have no common measure which is not also a common measure of the diagonal and side of the least square of the series; in other words, they have no common measure whatever.

Incompatibles (Lat. in, neg., con = cum, and patior, *I endure*). In Chemistry, salts and other substances are said to be *incompatible* which cannot exist together in solution without mutual decomposition. Thus the soluble salts of lead and of baryta are incompatible with sulphuric acid and the sulphates, because the sulphates of lead and of baryta are insoluble, and consequently thrown down in the form of precipitates.

Incompressibility (Lat. in, neg., con = cum, and premo, pressi, *I press*). That quality of bodies in virtue of which their volumes cannot be diminished. There are no substances, perhaps, absolutely incompressible. Liquids, however, resist compression with great force; but the experiments of Oersted, Perkins, and Canton have proved that water has its bulk sensibly diminished by increasing the pressure upon it. Nevertheless, the extent to which the compression can be carried is very small. On enclosing water within an iron cannon, the sides of which were three inches in thickness, and applying a very great force of pressure, the cannon burst before the volume of water had been reduced to 19-20ths of its original dimensions. A pressure equal to that of the atmosphere reduces the bulk of water only about forty-five parts in one million.

Incongruous (Lat. incongruus, *inconsistent*). In the theory of numbers, two numbers are said to be incongruous with respect to a given modulus, or third number, when the

INCUBATION

difference between those two numbers is not divisible by the modulus. Thus 16 and 3 are incongruous with respect to the modulus 7, but congruous with respect to the modulus 4. The *incongruous roots* of a congruence are the incongruous numbers which satisfy that congruence. Thus 8 and 16 are incongruous roots of $x^4 \equiv 1 \pmod{6}$. [CONGRUENCE.]

Incorporation (Lat. in, and corpus, *a body*). In Law, the formation of a legally constituted body with perpetual succession and corporate rights. [CORPORATION.]

Incrassate (Lat. incrassatus, *rendered thick*). In Botany, applied to bodies which are thicker than usual in proportion to their area, as in the leaves of succulents.

Increment, Decrement (Lat. incrementum and decrementum, *increase and decrease*). In Mathematics, the difference between two successive values of a variable quantity is called an *increment* or a *decrement* accordingly as the second value is greater or less than the first. A decrement being considered as a *negative increment*, we speak generally of the increment of a function which corresponds to a given increment of its independent variable. The determination and investigation of the ratio of two such increments is the primary object of contemplation in the *calculus of differences*, whilst the *differential calculus* is concerned chiefly with the *limit* to which this ratio approaches as the increments continually diminish. The *method of increments* was the name originally given to the calculus of differences by Dr. Brook Taylor, whose *Methodus Incrementorum*, published in 1715, contains the celebrated theorem which has since been made the basis of the differential calculus.

INCREMENT. In Rhetoric, a species of climax rising gradually from the lowest to the highest. [CLIMAX.]

Incrustation (Lat. incrustatio). In Architecture and Sculpture, a work fixed with cement, or cramp irons, into notches made to receive it; such as inlaid work, mosaics, &c.

Incubation (Lat. incubatio, *a brooding*). Hatching, or the lying down of an animal upon her own or another's eggs, communicating to them, and maintaining them at, her own temperature: a condition essential to their development. In many animals the development of the fœtus takes place after the exclusion of the egg, and whilst it is maintained in contact with the external surface of the parent's body, as in the crab and lobster tribes, beneath the caudal plates; or agglutinated to the surface of the abdomen, as in certain species of pipe-fish (*Syngnathus*); or concealed in cutaneous marsupial cavities, as in other species of *Syngnathus*, and the *Hippocampus*; but in these and other instances from the cold-blooded animals, the protection of the ova seems to be the object of their attachment to the parent, and not the communication of warmth or any other influence essential to their development. It is only in the Oviparous class with warm blood, or birds, that true incubation takes place, and in this

INCUBATION

class with the sole exception of the *Megapodes* or *Mound-birds*. Another characteristic of true incubation is that the place of the eggs determines that of the incubator, which can only perform its office by *lying down upon the eggs*; while in most of the examples of false incubation in the cold-blooded animals, the eggs are retained by special contrivances in contact with the parent, without occasioning any restraint upon her postures or movements.

That a due degree of warmth is the essential object of incubation in birds, is proved by the ancient and well-known practice of substituting artificial heat, by which fertile eggs are hatched in the same period, and the excluded chick is as fully and strongly developed as when produced by natural incubation.

The mean temperature of incubation is 100° Fahr.; it may vary from 95° to 105°, and towards the close of the process may be suspended for one or two hours, or for a longer period, according to the degree of extraneous heat which the eggs may derive from their situation, without fatal consequences to the embryo.

The power of communicating the requisite degree of warmth to their eggs arises in birds out of the unusual development of, and determination of blood to, a peculiar plexus of vessels distributed over the skin of the abdomen, and which, in most birds, is connected with a derivation of blood from the internal organs of generation, after the subsidence of the functional activity of the ovarium and oviduct, to the external integuments. The vascular, hot, and sensitive condition of the skin of the abdomen is the exciting cause of that uncontrollable propensity to incubate which the Greeks denominated *storge*, and which, with its associated phenomena of patience, abstinence, and self-denial, forms so remarkable a feature in the economy of birds. The egg of the bird presents several peculiarities in relation to the circumstances under which it is to be developed: its oval form permits a greater proportion of its surface to be in contact with the heat-communicating skin of the parent than if it had been a spherical body; while the shell, by virtue of its hard calcareous texture, and its arched disposition about the soft contents, sufficiently defends them from the superincumbent pressure. As warmth is the only essential influence which the egg derives from the parent, the shell is porous, and permeable to air, and the germ is surrounded by an adequate store of nutritious matter. This matter is of two kinds: the external, called the white of the egg, or albumen, which wholly disappears during the process of incubation; and the internal part, or yolk, inclosed in a peculiar membrane, and rendered lighter and of an orange colour by the admixture of a peculiar oil. The germ is situated at the superficies of the yolk, beneath the vitelline membrane, in the circular opaque white spot called the *cicatricula*, or *tread*; and a peculiar mechanism is superadded to the yolk, by means of which the

INCUBATION, ARTIFICIAL

germ-bearing surface of the yolk is always kept uppermost, and next to the warmest surface of the egg, and at the same time is relieved from the pressure against the hard shell, to which it must have been subject if the light yolk had not been restrained from rising to absolute contact with that surface. Both these purposes are effected by the attachment of two cords of condensed albumen, continued at one end from near the poles of the yolk, but a little more distant from the germ-bearing side than the line of the transverse axis, and expanding at the opposite end, which is lost in the layers of albumen near the poles of the egg. Thus, by their presence and place of attachment, these cords, called the *chalaria*, restrain and regulate the rising of the yolk; so that whichever way an egg be turned, the larger proportion of the light yolk always rises above the attachment of the restraining cords, with the cicatricula upon its summit. The period of incubation is generally directly as the size of the bird, but the degree of development which the chick attains prior to exclusion varies. As a general rule, it is inferior in birds of flight, as the Accipitrino and Passerine orders, than in the terrestrial, wading, and swimming birds; and the warmth and complexity of the nest bears relation to this difference of development. If the thrush had been forewarned that her young would be excluded from the egg naked and helpless, she could not have prepared beforehand a warmer and more comfortable abode than her instinct had led her to construct for their accommodation; and if with such a nest we contrast the rude recess of straw in which the hen deposits and incubates her eggs, it might be imagined that she knew beforehand that her chickens would come into the world well clothed, and strong enough at once to run about and pick up their own food. In this case, therefore, the nest relates only to incubation; in the other to incubation and subsequent rearing of the young; and according to the degree of development obtained during incubation, and the associated condition of the nest and habits of the parent, birds have been divided into two great groups, the *Aves altrices* and *Aves præcoces*. [Avis.]

Incubation, Artificial. Artificial incubation has been practised from a remote period by the Egyptians and Chinese; the former, indeed, have carried this process to such a high degree of perfection, as in many instances to have entirely superseded the use of the hen in hatching. It is effected either by means of an oven, stove, or steam, the principles of which will be found detailed in Ure's *Dictionary of Arts, &c.* This process has received considerable attention from the French philosophers; but perhaps the best exemplification of its results witnessed in Europe is given by the *Écocalcibon*, or egg-hatching machine, exhibited in London. This term, invented to express the process of artificial incubation, is coined from the Gr. *ἐκκαλέω*, *I call out*, and *βίος*, *life*. [PISCICULTURE.]

INCUBUS

Incubus (Lat. from *incubo*, *I lie upon*, because the sufferer feels as if something pressed upon his chest). The nightmare. The name incubus is derived from imaginary fiends or spectres. Many noble families were supposed to have their origin from the connection of incubi with females, as in the well-known instance of Robert of Normandy, called *le Diable*. For the theories on the intercourse of incubi and succubi with human beings, see Lecky, *Hist. of Rationalism*, ch. i. [EPHIALES.]

Incumbent (Lat. incumbens, *leaning upon*). A term applied to the holder of an office; in popular language chiefly of an ecclesiastical benefice.

INCUMBENT. In Botany, applied to an embryo when its radicle is folded down upon the back of the cotyledons.

Incumbered Estates' Act, Irish. In consequence of a variety of causes, among which the too general improvidence of Irish landholders, and their reluctance to part with the appearance of territorial rights after the substance had passed to their creditors, were the chief, most of the landed property in Ireland had fallen into an extremely inconvenient and anomalous legal position. In many instances the judgments, mortgages, and other charges on estates greatly exceeded their value; the owner was, in fact, only a collector for others; and the number and variety of these incumbrances was so great that a sale frequently became impossible: the Court of Chancery being unable to afford the necessary relief by reason of its forms, which require the assent and co-operation of all parties, however remotely interested. In this state of things the Irish Incumbered Estates' Act was passed in 1849, after the famine of 1847 had drawn general and serious attention to the economical condition of the island. This Act provided that an incumbered estate might be summarily sold on judicial decree (pronounced by a court of three commissioners created for the purpose), on the application of the owner or of any incumbrancer, providing for the application of the purchase money among the parties entitled, and relieving the purchaser from any trouble or risk, by giving him a parliamentary title free from incumbrances. The practical effects of this measure were abundantly and rapidly felt. In September, 1858, it was estimated that more than 8,000 conveyances had been executed under the authority of the court, and that 23,000,000*l.* had been received on account of purchase moneys of estates sold under it, of which 3,000,000*l.* came from English and foreign purchasers, the remainder from Irish. These statistics appeared so convincingly to establish the value of the institution, that the system was rendered permanent by the Irish Landed Estates' Act of 1858, and made applicable to all estates, whether incumbered or not.

In 1854 a similar measure was enacted for the West Indies (West Indies Incumbered Estates' Act, 17 & 18 Vict. c. 117, amended

INDEMNITY

by subsequent Acts), which can, however, only be put in force with the consent of each colony concerned. It is now in force in five islands, of which Jamaica is the principal, and extensive sales have been effected under it.

Incumbrance (Fr. *encombrer*, to *incumber*: Mod. Lat. *comber*, a *weir*—Ducange: Mr. Wedgwood, who denies—s. v. 'Comber'—that this word is derived from the Latin *cumulus*, a *heap*, connects it with the German *kummer*, Dutch *komber*, *trouble*). In Law, the general name for liabilities whereby property, and in especial property of freehold in lands and hereditaments, may be burdened; such as mortgages, dower, annuities, and the like. The rules of law and equity with respect to the adjustment of the rights and duties of different persons having interest in the inheritance, in respect of the discharge of incumbrances, are very minute and complicated. (Story's *Equity Jurisprudence*, § 486.)

Incunabula (Lat. *a cradle*). In Bibliography, a term applied to books printed during the early period of the art; in general confined to those which appeared before the year 1500.

Incurved (Lat. *incurvus*, *curved inwards*). In Zoology, when a part is curved inwards.

Indeclinable (Lat. *indeclinabilis*). In Grammar, a word admitting of no declension or inflexion. Adverbs, prepositions, particles, conjunctions, are all indeclinable. In classical languages, indeclinable nouns are the few nouns (chiefly borrowed by the Greeks and Latins from foreign languages) of which the termination is not altered in the several cases.

Indefinite (Lat. *indefinitus*, from *finis*, *an end*). In Botany, when stamens are above twenty in number; the word is applied to all other parts when their number is greater than can be readily counted. This term always refers in botany to number, and never to form.

Indefinite Integral. The general form of the sum of an infinite series of infinitesimal elements whose initial and final terms are undetermined. It may also be considered as any one of the functions which has a given function for its differential coefficient. The corresponding equivalent symbols for an indefinite integral are

$$\int F(x)dx \text{ and } \left(\frac{d}{dx}\right)^{-1} F(x).$$

[INTEGRAL CALCULUS.]

Indefinite Proposition. In Logic, one which has for its subject a common term, without any sign to indicate whether it is distributed or undistributed. [PROPOSITION.]

Indehiscent (Lat. *in*, and *dehisco*, *I gape*). In Botany, when the pericarpium of a fruit continues perfectly closed, without opening in any degree when ripe.

Indemnity (Lat. *in*, *neg.*, and *damnum*, *loss*). In Politics and Jurisprudence, a word of various significations, but applied usually to laws passed to relieve individuals from penalties to which they are liable in consequence of acting in an illegal manner. The Act of Indemnity, annually passed by the

INDENTURE

British parliament for many years prior to the repeal of the Test and Corporation Acts in 1828, was a measure for the relief of persons who had assumed any office without qualifying themselves for it by taking the oaths prescribed by those enactments. In Feudal Jurisprudence, the right of the lord to a certain duty payable by religious establishments to compensate him for the loss of those fines on alienation which would probably have accrued from time to time if their property had remained in lay hands, was termed *indemnity*. In the language of modern politics, compensations paid by a state to other states, corporations, or individuals, for losses sustained through its acts, bear the same name. Acts of indemnity are also sometimes passed to relieve ministers from the responsibility of measures exceeding their strict constitutional powers, taken by them when parliament was sitting, to meet some unforeseen public emergency, or in ignorance, it may be, that they had exceeded the powers vested in them by the constitution. Laws of *indemnity*, in the language of foreign jurisprudence, include laws for compensation. Thus in 1825 a law of indemnity was passed in France to compensate the losses sustained by the emigrants or their families, and those of persons who had been condemned to death for political offences in the course of the Revolution. The sum allotted to this purpose was an annual amount of 30,000,000 francs (about 1,200,000*l.*). A special commission was appointed to carry it into execution; but it appears that its labours were broken off before their completion by the political changes of 1830.

Indenture (from Lat. *dens, dentis, tooth*). In Law, a writing or deed comprising some contract between two or more parties. The name is derived from the ancient practice, according to which the original and counterpart original (to be retained by each party respectively) were written on the same skin of parchment, and then the two parts were separated by a notched or indented cut, so that when applied to each other they would appear to match. [DEED.]

Independence, Declaration of. In the History of the United States of America, the *Declaration of Rights* was adopted by the first general congress of the then revolted colonies which met at Philadelphia in September 1775. In this declaration that assembly claimed the right of internal legislation and taxation for the provincial legislatures, and declared various acts of the mother country to be infringements and violations of the rights of the colonists. The second congress, which met in May 1776, adopted on July 4 of that year a *declaration of independence*; by which, after again recapitulating the grievances complained of in the former declaration, it declared the colonies to be free and independent states, absolved from all allegiance to Great Britain. The first draught of this famous declaration was prepared by a committee of

INDEPENDENTS

five; consisting of Jefferson and Adams (both afterwards presidents), Franklin, Sherman, and Livingstone. Jefferson and Adams were afterwards deputed as a sub-committee to prepare the declaration itself; but, in the shape in which it finally appeared, it was in fact the work of the former.

Independents. A Protestant sect; so called because they maintain that every single congregation forms a church or independent religious society in itself, unconnected with, and not amenable to, any other. They consequently condemn everything like a national establishment of religion, whether episcopal or presbyterian. They have always maintained, speaking generally, Calvinistic doctrines: their only peculiarity consisting in their maintenance of independent ecclesiastical government.

On the reformation of religion in England, the great body of Protestants adopted the episcopal form of church polity, which was established as the national religion. But there were not a few who conscientiously thought that this polity too nearly resembled that which had been supplanted. These nonconformists, or dissentients from the established faith, are known in history under the derivative name of *Puritans*, as the followers of Novatian had been denominated in the third century. [CATHARI.] But while they forsook the national church, and condemned many of her tenets, they did not agree among themselves. They were, in truth, unanimous in nothing but in resisting the constitution of the predominant hierarchy. Some of them were in favour of a presbytery, such as Calvin had established in Geneva, and as Knox had introduced into Scotland. Others were against every form of state religion, but regarded each congregation of Christians as being *jure divino* a complete and independent church. Of this latter opinion, which constitutes the pure principle of English Independency, the author and great advocate was Robert Brown, who was originally a clergyman of the episcopal church, from which he seceded, and avowed his new doctrines about the year 1580. (Neal's *History of the Puritans*, vol. i. ch. vi. London 1822.) Brown is represented by Neal as a vehement and popular declaimer, and insinuating in his manners. He not only advocated the leading principles of Independency as we have stated them above, but taught that the priesthood was neither a distinct order, nor conferred an indelible character; that every person regarded by the majority of a congregation as qualified to teach might be set apart for that office by the election of his brethren, and by imposition of their hands; in like manner, by their authority, he might be reduced again to the rank of a private Christian; and further, that any member who thought proper to exhort or instruct the brethren enjoyed the inherent right of doing so, or of *prophesying* before the whole assembly. Hence after the stated pastor had finished his services, the ordinary members were allowed to communicate in public their sentiments on any religious sub-

INDEPENDENTS

ject. But while Brown enforced these views, and claimed liberty of conscience to himself, he was not willing to allow similar privileges to other sects, particularly the church of England.

Brown and his followers suffered severely for their principles. He was committed, as he afterwards boasted, to thirty-two prisons in succession, in some of which he could not see his hand at noonday. Nor were his adherents more mercifully treated: many of them were fined and imprisoned, and some put to death. (Neal i. 313.) Under these circumstances, a body of the party, with Brown at their head, fled to Holland, and founded churches at Middleburg, Amsterdam, and Leyden. But these establishments were neither solid nor lasting. When the Brownists were delivered from the hands of the bishops their oppressors, they quarrelled among themselves; and their leader, weary of his office, came back to England in 1689, and returned into the church which he had so long and so severely calumniated.

The Brownists that still remained in Holland, learning moderation from experience, were not unprepared to modify or reform the severe discipline of their founder. This judicious change was brought about by John Robinson of Norfolk, member of the congregation at Leyden. (Mosheim v. 359-60.) Hitherto the sect had been called Brownists: they now renounced that name, and have since been known under the title of Independents; and Robinson, who wrote an apology for them (*Apologia justa et necessaria pro Exulibus Anglicis, qui Brownistæ vulgo appellantur*, Lugd. Batav. 1619, 8vo.), was considered as their founder. They laid aside that hostility to other sects which Brown had inculcated, and differed with them only on the subject of church government. They were also much more attentive than the Brownists had been to the establishment of a regular ministry in their communities; for, while the latter allowed all ranks and orders of men to teach in public, the Independents had, and still have, a certain number of ministers chosen respectively by the congregations where they are fixed. Nor is any person among them permitted to speak in public till he has received the sanction of the congregation.

Independency, thus put on a more rational footing in Holland, was introduced into England by Mr. Henry Jacobs, who, in 1616, established the first Independent or Congregational church in this country. For some time, however, the sect made but slow progress in England. Its members concealed their principles from public view, to avoid the penal laws in existence against nonconformists. But during the latter part of the reign of Charles I. the Independents assumed greater courage, and publicly avowed their principles. From this period their progress was rapid; a circumstance that may be imputed in no slight degree to the support of Oliver Cromwell, who espoused their cause and enrolled himself among the list of their mem-

bers. They probably were, during Cromwell's time, the most powerful and important religious body in England; though for a few years previous to the death of Charles I. the Presbyterians may be said to have had the ascendancy. Indeed, presbytery had been established by Act of Parliament as the national church; and it was chiefly owing to the growing influence of the Independents that this Act was rendered inoperative. (Murray's *Life of Samuel Rutherford*, chap. viii. Edinburgh 1628.) Notwithstanding the *Apology* written by Robinson, the Independents as a body had not agreed on any standard of faith and discipline; but, in the year 1658, their leading members held a meeting in London, under the sanction of the Protector, and passed 'The Savoy Confession, or a Declaration of the Faith and Order owned and practised by the Congregational Churches in England, agreed upon and consented unto by the Elders and Messengers in their Meeting at the Savoy, Oct. 12, 1658.' This Confession, and Robinson's *Apology*, on which it is mainly founded, contain a synopsis of their various tenets; and from these it appears, as Mosheim remarks, 'that they differed from the Presbyterians or Calvinists in no single point of any consequence, except that of ecclesiastical government.' (Adam's *Religious World Displayed*, ii. 312-13.)

Thus matters stood at the date which we have just specified. What might have been the issue of the struggle between the Independents and Presbyterians if Cromwell had lived, or if his son had retained power, cannot be said. But the restoration of Charles II., and with him of the episcopal church, put an end to the influence of both sects. The Act of Uniformity, passed in 1662, was designed to crush nonconformists, particularly the Independents and Presbyterians. The Act required from clergymen a direct recognition of the principle of episcopacy. The effect of this was the retirement of about 2,000 clergymen from their respective churches—Independents, Presbyterians, and Baptists; whom Dissenters still characterise in history as 'the illustrious two thousand,' 'the ejected members,' or 'the Bartholomew worthies.' The Independents, however, though proscribed, still subsisted; but in a state of persecution, dejection, and weakness. The Revolution of 1688, and the Act of Toleration, which was passed in the subsequent year, brought them peace and the free exercise of their religion. They were now a small body as compared with the Presbyterians; but the two sects, having much in common, and differing only as to church government, entered into an association with each other, under certain heads of agreement, which tended to the maintenance of their respective institutions. (Whiston's *Memoirs of his Life and Writings*, vol. ii.; Mosheim v. 361-63.)

Since the period of the Revolution, the Independents have greatly increased both in numbers and importance. The extraordinary revival of religious zeal which took place about

INDETERMINATE

the middle of last century, under the influence of the two Wesleys and Whitfield, was of essential service to the sect. Many other persons, awakened to a deeper sense of religion, refusing to unite with any of the three bodies of Methodists, the Wesleyan, the Whitfieldian, or the countess of Huntingdon's, joined the Independents, and formed numerous churches in connection with that sect. The Independents have long ago withdrawn from their association with the Presbyterians, or indeed with any body of Dissenters, and act by themselves.

Of the extent and influence of the Independents in England, a pretty correct idea may be formed from the number of their colleges or academies, and of their chapels. The former are exclusively confined to the education of ministers belonging to their own denomination. Some of these institutions are wealthy endowments: others of them are supported by annual subscriptions. Their number is ten; the oldest, at Homerton, Middlesex, having been founded in 1730. The number of Independent chapels in England and Wales, according to the census of 1851, was 3,244. In Scotland the Independents have upwards of 100 chapels, and in Ireland about 30; but it is reckoned that they have no fewer than 1,000 congregations in the United States; and the best authorities concur in stating that their numbers are on the increase.

Indeterminate (Lat. *indeterminatus, undefined*). In Botany, when a stem is never terminated by a flower, nor has its growth stopped by any other organic cause: example, *Veronica arvensis*.

INDETERMINATE. In Mathematics, this term is employed in various ways, and sometimes loosely. An *indeterminate problem*, for instance, denotes one which has an *infinite* number of solutions, not arbitrary but correlated; the indetermination arising, in fact, not from a *total*, but from a certain *degree of insufficiency* in the data; if the data were such as to render the problem capable of receiving a *finite* number of solutions, that problem would no longer be considered as indeterminate. [DETERMINATE PROBLEM.] *Indeterminate coefficients*, again, simply denote *unknown* coefficients. *Undetermined* would here be a less objectionable term.

Indeterminate Analysis. In its widest sense might be defined as that branch of Mathematics which has for its object the investigation of problems which admit of an infinite number of solutions. Ordinarily, however, the term is restricted to that branch of Algebra whose object is the determination of all possible solutions, in positive (or negative) integers, of a system of equations involving more unknown terms than there are equations. The general form of an *indeterminate equation* of the first degree is $ax + by = c$, where a , b , and c are positive or negative integers. If a and b have a common measure which will not divide c , the equation can, obviously, have no integral solutions. If a and b are prime to one another, however, then an integral solution may be found by convert-

INDETERMINATE COEFFICIENTS

ing $\frac{a}{b}$ into a continued fraction, and finding the convergent $\frac{p}{q}$ immediately preceding $\frac{a}{b}$. We

shall then have $aq - bp = \pm 1$ [CONTINUED FRACTION], or $a(\pm qc) + b(\mp pc) = c$; so that $x = qc$ and $y = -pc$, or else $x = -qc$ and $y = pc$, will be an integral solution of the given equation. One such solution (α, β) being found, an infinite number can be at once determined. They are all included, however, in the formula $x = \alpha + bt, y = \beta - at$, where t is any integer whatever. The solution of a system of indeterminate equations of the first degree is reduced to that of the case just described. In systems of equations of higher degrees, the difficulties are immensely increased. The theory of indeterminate equations is closely connected with that of congruences, and thus forms a branch of the general theory of numbers; the works on the latter subject, therefore, may be consulted for further details.

The oldest treatise on the subject of the indeterminate analysis is the *Arithmetic* of Diophantus of Alexandria, the best edition of which is that of Toulouse, 1670; with a *Commentary* by Bachet, and notes by the celebrated Fermat. On the revival of the mathematical sciences, the subject was extensively cultivated by Fermat, Descartes, Wallis, Lord Brouncker, and others. One of the most luminous elementary treatises on the subject is contained in the second volume of Euler's *Algebra*.

Indeterminate Coefficients. A method of analysis invented by Descartes, and of very extensive application in the higher mathematics. The principle of the method of indeterminate coefficients consists in this, that if we have an equation of this form,

$$A + Bx + Cx^2 + Dx^3 + \&c. = 0,$$

in which the coefficients A, B, C are constant quantities, and x a variable which may be supposed as small as ever we please, each of these coefficients, taken separately, is necessarily equal to zero; that is to say, we must always have $A = 0, B = 0, C = 0, \&c.$, whatever may be the number of terms of the given equation.

In fact, since x may be supposed as small as we please, it is always possible to render the sum of all the terms of the given equation which have x for a factor as small as we please; that is, the sum of all the terms following the first may be rendered as small as we please. Hence the first term differs from zero only by a quantity which may be less than any assignable quantity; but the first term A being constant, its difference from zero cannot be any finite quantity assumed at pleasure, for this would suppose it to be variable. It follows, therefore, that A can be nothing else than zero; that is, we must have $A = 0$, whence there remains

$$Bx + Cx^2 + Dx^3 + \&c. = 0.$$

Divide this last equation by x , and there results

$$B + Cx + Dx^2 + \&c. = 0;$$

INDEX

and, for the same reasons as before, it is manifest that we must have $B=0$. Proceeding in the same manner, we find successively $C=0$, $D=0$, &c.

The principle here explained is extremely fertile in its applications; its rigorous demonstration, however, involves certain difficulties, for the statement of which we may refer the reader to De Morgan's *Algebra*.

Index (Lat.). A term often applied to the forefinger.

INDEX. In Bibliography, an alphabetical table, containing the principal subjects of a work, or of words employed in it, with references to the part of the work in which they are to be found. Many independent works, containing catalogues of various kinds, have been also entitled *index*.

INDEX. In Mathematics, this term may generally be considered as synonymous with *exponent*. In some branches, however, as in the theory of numbers, a conventional distinction is made between the two terms which it may be well to notice.

The *index of a number to a given base*, and for a given prime *modulus*, of which that base is a primitive root, is the index of the power of the base which is congruous to the number. Thus if r denote a primitive root of the prime p , in other words a primitive root of the congruence $x^{p-1} \equiv 1 \pmod{p}$. Then by FERMAT'S THEOREM any number n , prime to p , is congruous to some power of r , say $r^a \equiv n \pmod{p}$. This being the case, a is said to be the *index of n to the base r for the modulus p* . It is clear that in place of a we may regard, as the index of n , any number congruous to a for the modulus $p-1$; so that symbolically expressed we have

$$a \equiv \text{Ind}_r n, \pmod{p-1}.$$

On the other hand, the *exponent to which the number n appertains* is the number of incongruous powers of n for the modulus p ; this exponent has but one value, whereas the index of n , being obviously dependent upon the choice of the primitive root r , may have many values.

In 1839 the academy of Berlin, at the suggestion of Jacobi, who undertook the editorship, published the *Canon Arithmeticus*, which consists of a series of tables containing the numbers corresponding to given indices, and indices corresponding to given numbers.

INDEX. In Printing, the hand  used for pointing out a remarkable passage, or one requiring particular attention.

INDEX CORRECTION. The index error or correction of astronomical instruments, such as the sextant, is the difference, measured on the limb, between the zero point and the spot where the zero point would be when the movable and fixed reflectors are parallel.

INDEX EXPONENT. [MATHEMATICS.]

Index Expurgatorius (Low Lat.). A catalogue of works, which the church of Rome prohibits the faithful from reading, or con-

INDIAN OCEAN

demns as heretical. It is annually published at Rome under the superintendence of a special congregation of cardinals, called the 'Congregation of the Index.'

Index of Refraction. In Optics, the constant ratio which exists for the same media between the sines of the angles of incidence and refraction. Thus, with respect to a ray of light falling obliquely on the surface of water, the sine of the angle of incidence is found by experiment to be to the sine of the angle of refraction in the constant ratio of 1.336 to 1. Hence 1.336 is the index of refraction in water [REFRACTION.]

India Paper. [PAPER.]

Indian Archipelago. This name is given to the vast and important group of islands extending between China and Australia. A long string of elongated islands, commencing with Sumatra and extending in a crescent shape to New Guinea, forms the boundary to the southwest. Within this outer line, Borneo, the Celebes, and the Philippine Islands, with Formosa, enclose the China Sea. Many of these islands are the richest and among the largest of all the islands of the earth. They are, however, little known, and a large number are not adapted for civilised man. A chain of volcanoes extends along the whole line, the active cones being closer together and more frequently in eruption than in any other group.

Of these islands, New Guinea is especially gigantic, and has rarely been entered by travellers. It measures 1,200 miles in length by nearly 500 in breadth, and its mountains attain a height of 16,000 feet. Borneo is somewhat smaller, but is rich in mineral and vegetable wealth beyond all known islands. The climate is healthy in many parts, although the island is crossed by the equator. Sumatra and Java are hardly less remarkable. The other groups are important, and are not far from the direct line of navigation from India to the China ports and the Japanese islands.

Indian Architecture. [ARCHITECTURE, INDIAN.]

Indian Corn. The popular name of the Maize, *Zea Mays*, a stout-growing grass, much cultivated as a corn crop in America and Southern Europe.

Indian Fire. A pyrotechnic composition consisting of seven parts of sulphur, two of realgar, and twenty-four of nitre. It burns with a brilliant white light.

Indian Ink. A species of ink used in water-colour painting, and for the lines and shadows of drawings. It is principally manufactured in China, and there used for writing. From the experiments of Dr. Lewis it appears to be a compound of fine lampblack and animal glue. [INK.]

Indian Ocean. This portion of the great ocean is in some respects an appendage to the Pacific, but is well separated from it by the great and important chain of islands of the INDIAN ARCHIPELAGO and the west coast of

INDIAN RED

Australia. It is a vast triangular basin, shut in to the north by the land of Southern Asia, Eastern Africa, and the chain of islands just mentioned, and only opening freely to the east and west between Van Diemen's Land on the one side and the Cape of Good Hope on the other, and the lands and icy promontories projecting beyond the Antarctic circle. Within this space is an area of 23,000,000 square miles.

The Indian Ocean includes several inland seas, as the Red Sea, the Persian Gulf, the Arabian Sea, and the Bay of Bengal. It also contains the vast but little known island of Madagascar. The peninsula of India projects far into it from the north in a regular triangle, terminated by Ceylon, and continued several degrees south of the equator by a chain of islands chiefly coralline. The oceanic warmth equator within it is almost everywhere ten degrees north of the terrestrial equator.

The winds of the Indian Ocean are periodical, and many parts of it are subject to storms of very extraordinary violence. The periodic winds are called **Monsoons**. The great storms are limited to a belt of ocean whose northern limit is from five to eight degrees, and their southern limit between thirty and forty degrees south of the equator. The most severe storms occur on the African side of the ocean.

There are several broken currents in the Indian Ocean, but none of great importance except the **MOZAMBIQUE CURRENT**, passing between Madagascar and the mainland of Africa. A special account is given of this current, to which the reader is referred.

The coast line of the Indian Ocean is very considerable compared with its area; but, except in the larger seas already referred to, the coast is not very deeply indented. A very large and important drainage is received into it—the Ganges and Irawaddi, the Indus and Euphrates, and the great African river Zambesi, all pouring their waters into it. The latter river, however, though of the first class, does not appear to convey much fresh water. The Australian rivers are also inconsiderable affluents.

Indian Red. A kind of red ochre with a tinge of purple, imported from the Persian Gulf in small lumps, and as a coarse hard gritty powder. It is principally composed of silicate of iron; but the same name is applied to another mineral, also of a red colour, which consists chiefly of peroxide of iron. The well-known pigment Indian Red is made from these substances.

Indian Rubber. The inspissated milky juice of *Siphonia elastica*, *Ficus elastica*, and other plants. A curious and important modification of this article was discovered by Mr. Thomas Hancock; it is generally known under the name of *vulcanised Indian rubber*. It is caoutchouc combined with a very small proportion of sulphur. The several modes of effecting this are fully described in the specification of his patent. Vulcanised Indian rubber does not, like the ordinary article,

INDICATRIX

become hard and rigid by cold, and it bears a very high temperature without change of properties. It is much more perfectly elastic than the common rubber, so that when stretched it does not acquire a set, but returns when released to its former dimensions. This discovery has rendered caoutchouc applicable to an infinity of purposes, for which, in its ordinary state, it is either unfit or objectionable. Among the most remarkable properties of vulcanised caoutchouc, is the resistance which it affords to naphtha, oil of turpentine, ether, oils, and a variety of other substances which are comparatively without action upon it, whereas they either soften or dissolve common rubber. [CAOUTCHOUC.]

Indian Yellow. [EUXANTHINE.]

Indianite. A mineral which occurs in granular masses, associated with Garnet, Felspar, and Hornblende. It is hard enough to scratch glass, and of a white or grey colour.

Indicative Mood (Lat. *indicativus*, from *indico*, *I point out*). That form of a verb which expresses a simple or unconditional judgment. [GRAMMAR.]

Indicator (Lat.). In Anatomy, a muscle of the lower part of the forearm which extends the forefinger.

INDICATOR. In Mechanics, the instrument employed for ascertaining the real power exercised by a steam engine, as well as the efficiency of the internal parts that are connected with the arrival and distribution of the steam. It acts by indicating the actual pressure in the cylinder during each stroke, as well as the time and manner in which the steam is admitted to and shut out by the valves which are placed upon the inlet pipe from the boiler.

INDICATOR. In Zoology, a genus of birds belonging to the cuckoo tribe (*Cuculidae*), characterised by a straight finch-like bill, with compressed sides and a triangular base, the culmen and gonys being equally inclined towards the tip, and the gonys angulated; wings lengthened, pointed; tail moderate, rounded; feet short; middle toe much longer than the tarsus.

The species of *Indicator* are remarkable for their habit of indicating the nests of bees, and of guiding men to them by their motions and cries; whence both their scientific name and their common appellation of *honey-guides*.

Indicatrix. A name given by Dupin to a certain quadric curve which, traced upon the tangent plane of a surface, serves to determine all the accidents of curvature at the point of contact. Innumerable surfaces of the second order can be drawn to touch a given surface at a given point; so that the sections of both surfaces, by a plane through their common normal, shall have contacts of the second order. From this it follows that the curvature of both surfaces is identical at their point of contact. [CURVATURE OF SURFACES.] Now the section of this quadric by any plane parallel to the common tangent plane of the two surfaces is similar and similarly situated to the

INDICATRIX, SPHERICAL

indicatrix; whence it follows, from the well-known theory of the curvature of quadrics, that the squared radii vectores of the indicatrix are proportional to the radii of curvature of the parallel normal sections, that the axes of the directrix are parallel to the lines of curvature through the point of contact, and that the asymptotes of the indicatrix are parallel to the inflexional tangents, and its conjugate diameters to conjugate tangents. According as the indicatrix is an ellipse, a hyperbola, or a parabola, the point on the surface is said to be *elliptical*, *hyperbolic*, or *parabolic*.

It can be shown (Salmon's *An. Geom. of Three Dimensions*) that every tangent plane cuts the surface in a curve having a double point at the point of contact. Now the tangents at this double point will be imaginary, real, or coincident; that is to say, the point of contact will be a conjugate point, an ordinary double point, or a cusp, according as the same is elliptical, hyperbolic, or parabolic. Every point of a developable surface is parabolic, and on other surfaces the locus of parabolic points separates the elliptical from the hyperbolic points. This locus is the intersection of the surface with its Hessian, and is in general a curve of the $4n(n-2)^{\text{th}}$ order, if n be the order of the original surface. The tangent plane at a parabolic point is of the kind called *stationary*, because it coincides with one of the consecutive tangent planes, all of which, it may be remarked, pass through the line with which, at a parabolic point, the two inflexional tangents coincide. Thus parabolic points on a surface are analogous to points of inflexion on a plane curve. At the latter, the polar quadric degenerates to a couple of right lines; at the former, to a cone. The equation of the Hessian is precisely the expression of these conditions. Besides Dupin's *Développements de Géométrie*, and the work of Dr. Salmon, already cited, the reader must consult the more recent mathematical journals and *Phil. Trans.* for further information on this important branch of the theory of surfaces.

Indicatrix, Spherical. In Geometry, the spherical curve traced, on a unit-sphere, by the extremity of a radius drawn parallel to the tangent of a non-plane curve. The spherical indicatrix is often of use in studying the properties of non-plane curves. The plane of the great circle touching the indicatrix is obviously parallel to the osculating plane of the curve; its geodesic angle of contact is equal to the angle of torsion of the latter; its rectilinear tangents are parallel to the principal normals; its spherical evolute is the indicatrix of the cuspidal edge of the rectifying developable, &c. &c.

Indicavit (Lat. *he has shown*). In Law, a species of the writ of prohibition. It lies for a patron of a church, whose incumbent is sued in the spiritual court by another clergyman for tithes amounting to a fourth part of the profits of the advowson; and depends on stats. West. 2. c. 5, 13 Edw. I. stat. 4.

INDICTMENT, PROCESS BY

Indicito. [INDICOLITE.]

Indiction (Lat. *indictio*, a *declaring*). In Chronology, a cycle or period of fifteen years, the origin of which is involved in obscurity. Unlike other cycles, the indiction has no reference to any astronomical phenomena; but is supposed to relate to certain judicial acts, probably the publication of tariffs of the taxes, which took place at stated intervals under the Greek emperors. The Cæsarean indiction fell on the 8th of the calends of October (24th of September); the indiction of Constantinople (beginning A.D. 312) on the 1st of September; the pontifical indiction on the calends of January. It is a date commonly employed in very ancient charters. The commencement of this computation is generally referred to the 1st of January of the year 318 of the common era; hence, by counting backwards, it will be found that the first year of our era corresponded to the fourth of one of the cycles of indiction. The year of indiction corresponding to any other year of our era is found therefore by this rule: Add 3 to the date, divide the sum by 15, and the remainder is the year of the indiction. The remainder 0 indicates the 15th of the cycle. Thus the year 1800 was the third of the indiction. (See as to the historical commencement of the era of indictions, Gibbon's *Decline and Fall*, ii. 223, last ed.; *Mém. de l'Acad. des Inscrip.* vol. xli.)

Indictment, Process by (Lat. *indico*, *I proclaim against*). In Law, all persons, without exception, are liable to be arrested on a warrant of a justice of peace, if charged on suspicion with a crime; and some officers, as the sheriff or constable, have the power of apprehending without a warrant on some occasions. When the party is arrested and brought before a justice of peace, he is examined, and the information of those who came with him is taken; and the depositions of the witnesses, if taken down in the presence of the prisoner, are evidence against him on the trial. If the offence be bailable, the justice must then take sufficient bail on the part of the prisoner. If otherwise, he commits him to prison; and the witnesses are bound over to attend and give evidence, the king being in all cases the nominal prosecutor. The grand jury being summoned by the sheriff (at every session of the peace, commission of oyer and terminer and gaol delivery), consisting of not fewer than twelve nor more than twenty-three of the principal men of the county, receives the *indictment* or *presentment* (as it is also termed) preferred against the prisoner, and either *finds* or *ignores* it; returning it into court, in the first case, indorsed a *true bill*; in the latter *not found*.

An indictment may be found in the absence of the prisoner; but cannot be tried unless he personally appears. The summons, when he is absent, in order to bring him into court, is by *capias*. When the prisoner appears on this process, or voluntarily, or is brought up in custody, he is *arraigned*; that is, called

INDICTMENT, PROCESS BY

before the bar to answer the indictment. If the prisoner refuse to answer (in which event he was subjected, in former days, to the famous *peine forte et dure*, by which it was intended to torture him into pleading, in order that the forfeiture of his goods might attach), a plea of not guilty is now recorded, and the trial proceeds; if he plead guilty, judgment is awarded. Otherwise he may plead—1. To the jurisdiction; i.e. that the court before which he is arraigned is not competent to try the offence. 2. Formerly in abatement for misnomer; but the advantage of this plea is now taken away by 7 Geo. IV. 3. He may demur to the sufficiency in law of parts of the indictment. 4. He may plead one of the four special pleas in bar (former acquittal, former conviction, former attainder, and pardon). 5. He may plead not guilty of the crime alleged. If the prisoner plead not guilty, the fact of his guilt is forthwith tried on examination of witnesses by the petty jury. The nobility, it must be observed, are tried by their peers for treason or felony, and misprision of these crimes; but in other cases by a jury. The jurors are taken by the panel or list returned by the sheriff; and *criminal offences* are tried by the same common jurymen who try the issue of facts in civil cases in which a *special jury* has not been demanded. [JURY.] The rules of evidence observed on the trial are mostly the same with those which prevail in civil actions. [EVIDENCE.] One testimony, however, peculiar to this branch of law, is that of an accomplice; but it is considered essential that his testimony should be confirmed by other evidence. The verdict of the jury must in all cases be unanimous. After trial and conviction follows judgment, unless arrested by motion for that purpose, which it still may be on some exceptions to the indictment in point of law. **BENEFIT OF CLERGY** [which see] was usually prayed after conviction; and was held, in cases where not abolished by statute, to discharge the claimant from the capital part of the punishment. But this ancient privilege, which had long been founded on a mere fiction of law, was abolished by 7 & 8 Geo. IV. c. 28. Forfeiture of real property, absolutely, is a consequence of judgment in cases of high treason. The forfeiture of goods and chattels relates to, that is takes effect upon, conviction; but fraudulent conveyances without consideration, in order to escape the forfeiture by the transfer of the property after or in contemplation of indictment, are void as against the king. The sentence of punishment pronounced or recorded on judgment is in some cases fixed and stated, so that the judges cannot modify the statutory penalty; in others (as in all offences at common law unregulated by statute) it is wholly or partly discretionary.

A criminal judgment may be reversed by writ of error for notorious mistakes and irregularities. A reprieve suspends the execution of a judgment: a pardon avoids the judgment

INDIGO

altogether; and a pardon may be conditional on the prisoner's submitting to a substituted punishment, which is the ordinary mode of mitigating the severity of the law in capital felonies. [LAW, CRIMINAL.]

Indigestion. [DYSPEPSIA.]

Indigetes (Lat.). The Latin title for the indigenous heroes of the land, who after death were ranked among the gods; as *Latinus*, *Æneas*, *Romulus*, and others.

Indigo. A blue substance much used as a dye-stuff. It has been the subject of much chemical research, and its direct and indirect derivatives are very numerous. The best indigo is obtained from an Asiatic and American plant, *Indigofera tinctoria*. The plant is bruised and fermented in vats of water, during which it deposits indigo in the form of a blue powder, which is collected and dried, so as to form the cubic cakes in which it usually occurs in commerce. Indigo is insoluble in water; when heated it yields a purple vapour, which condenses in the form of deep blue or purple acicular crystals termed *indigotin* = $C_{16}H_8O_2N_2$, which may be regarded as pure *indigo-blue*. When indigo is exposed to the action of certain deoxidising agents, it becomes soluble in alkaline solutions, losing its blue colour and forming a green solution, from which it is precipitated by the acids *white*; but it instantly becomes blue by exposure to air. This *white indigo* has been termed *indigogen* or *reduced indigo* = $C_{16}H_{12}O_4N_2$, so that in respect to ultimate composition, indigogen is a hydride of indigotin, and the white soluble condition of indigo passes into the blue insoluble condition by the abstraction of two atoms of hydrogen. Indigogen is best obtained by mixing 3 parts of finely powdered and pure indigo with 4 of green vitriol, 5 of slaked quicklime, and 100 of water, repeatedly shaking the mixture. In about twenty-four hours the supernatant liquor, which is transparent, and of a green colour, is to be decanted off, and poured into dilute hydrochloric acid, when the deoxidised indigo is thrown down; but in order to prevent its absorbing oxygen and becoming blue, it must be most carefully excluded from the contact of air, which may be effected by siphoning it off into the acid, collecting it in vessels filled with hydrogen, and washing it with water deprived of air and holding in solution a little sulphate of ammonia.

When indigo is dissolved in concentrated sulphuric acid, it forms a deep blue liquid, known to the dyers by the name of *Saxon blue*. The great mart for indigo is Bengal, and the other provinces subject to the presidency of that name, from the twentieth to the thirtieth degree of north latitude; but it is also cultivated, though not nearly to the same extent, in the province of Tinnevely, under the Madras government; in Java; in Luconia, the chief of the Philippine Islands; and in Guatemala and the Caraccas in Central America. The following remarks, from the *Commercial Dictionary*, will exhibit the history of this now indispensable commodity, and the difficulties

INDIGO

with which it had to contend before it obtained a permanent footing in the commerce of Europe. 'It appears pretty certain that the culture of the indigo plant, and the preparation of the drug, have been practised in India from a very remote epoch. It has been questioned, indeed, whether the *indicum* mentioned by Pliny (*Hist. Nat.* lxxv. c. 6) was indigo; but, as it would seem, without any good reason. Pliny states that it was brought from India; that when diluted it produced an admirable mixture of blue and purple colours (*in diluendo misturam purpureæ ceruleique mirabilem reddit*); and he gives tests by which the genuine drug might be discriminated with sufficient precision. It is true that Pliny is egregiously mistaken as to the mode in which the drug was produced; but there are many examples in modern as well as ancient times to prove that the possession of an article brought from a distance implies no accurate knowledge of its nature, or of the processes followed in its manufacture. Beckmann (*Hist. of Inventions*, vol. iv. art. 'Indigo') and Dr. Bancroft (*Pernicious Colours*, vol. i. pp. 241-252) have each investigated this subject with great learning and sagacity; and agree in the conclusion that the *indicum* of Pliny was real indigo, and not, as has been supposed, a drug prepared from the *isatis* or woad. At all events, there can be no question that indigo was imported into modern Europe, by way of Alexandria, before the discovery of the route to India by the Cape of Good Hope. When first introduced, it was customary to mix a little of it with woad to heighten and improve the colour of the latter; but, by degrees, the quantity of indigo was increased; and woad was, at last, entirely superseded. It is worth while, however, to remark, that indigo did not make its way into general use without encountering much opposition. The *growers of woad* prevailed on several governments to prohibit the use of indigo! In Germany, an imperial edict was published in 1654, prohibiting the use of indigo, or *devil's dye*, and directing great care to be taken to prevent its clandestine importation; "because," says the edict, "the trade in woad is lessened, dyed articles injured, and money carried out of the country!" The magistrates of Nuremberg went further, and compelled the dyers of that city to take an oath once a year not to use indigo; which practice was continued down to a late period. In 1598, upon an urgent representation of the states of Languedoc, at the solicitation of the woad growers, the use of indigo was prohibited in that province; and it was not till 1737 that the dyers of France were left at liberty to dye with such articles, and in such a way, as they pleased.'

Indigo blue exists in fresh urine as indican, which passes into insoluble indigo blue during the fermentation of the liquid. It has also been found in cow's milk. Indigo, when submitted to dry distillation, yields amongst other products a considerable quantity of ani-

INDIVISIBLES

line, the remarkable organic base from which the celebrated coal-tar colours are produced.

Indigogermene. *Indigo white*. [INDIGO.]

Indigoilite. A name given to blue *Tourmalines* on account of their colour.

Indigoetic Acid. An acid obtained by boiling indigo in nitric acid diluted with an equal weight of water. It forms white crystals, very soluble in hot water, but very sparingly soluble in cold water.

Indigoetin. The sublimate obtained by heating indigo. [INDIGO.]

Indin. A pulverulent rose-coloured body produced by the action of potash on sulphosathyd, a derivative of indigo.

Individual (Lat. *individuus*, that cannot be divided). In Biology, that organic whole which is generated, may generate, and dies. Some would restrict the definition to a special mode of generation, as, e.g., from an egg or seed directly fertilised by sperm or pollen. According to this opinion, all the well-grown 'mottled laurels' (*Aucuba japonica*) in England, all the Aphides that swarm upon a rose-bush, and, possibly, every drone of a hive, are severally disentitled to be called *individuals*, and are held to be mere parts and outgrowths of one and the same indefinitely extended *individual*; which individual, recognised as such agreeably with the restricted definition, prior to such outgrowths, may have long been dead and rotten; as, e.g., in the case of the Aphis from the directly fertilised *germ-cell* dying after giving birth to the progeny from derivatively fertilised *germ-cells*; and in the case of the mother-bee from the primarily fecundated egg, dying after oviposition of the secondarily fecund eggs from which male bees only are developed. Nothing is needed but a recital of the consequences, to stultify the definition of an organic *individual* as 'the total result of the development of a single egg or seed,' or 'the entire product intervening between one act of sexual generation or direct fertilisation and another.'

INDIVIDUAL. In the Fine Arts, that which is proper or peculiar to a single object of a species.

Indivisibles (Lat. *indivisibilis*). Infinitely small quantities which admit of no further division.

The *method of indivisibles* is the name given to a peculiar species of calculus, invented by Cavalieri, a disciple of Galileo, and much used by mathematicians before the invention of the method of fluxions or of the differential and integral calculus, for which it prepared the way, and of which to a certain extent it supplied the place. Its logic, perhaps, is inferior to that of the infinitesimal calculus, but its results are equally accurate. Lines are considered as composed of points, infinite in number, surfaces as composed of an infinity of lines, and solids again as aggregates of surfaces. Cavalieri was born at Milan in 1598; his *Geometria Indivisibilis Continuarum* &c. was published at Bologna in 1635. His method of indivisibles

INDO-EUROPEAN

was attacked by Guldinus, to whom Cavalieri replied in a subsequent work entitled *Exercitationis Geometricæ Lex*, and published in 1647. Roberval also laid claim to the invention of the method of indivisibles, but his publications on the subject were posterior to those of Cavalieri. (*Mém. de l'Acad. Roy. des Sciences*, t. 6; Paris 1780.)

Indo-European (compound of *Indian* and *European*). A term (stigmatised by Dr. R. G. Latham as 'erroneous and inconvenient') used to include the German, Sarmatian, Græco-Latin, Keltic, and Skiptar 'races;' when restricted to the three first, the term *Indo-Germanic* is used. Such terms 'keep their place, and must be used, however unfit for use.' (Latham.) Upon the hypothesis that all the above nations are of common origin, the term *ARYAN* has been proposed [which see].

Indorsement. [EXCHANGE.]

Inducement (Lat. *induco*, *I lead into*). In Law, a term used especially in various cases to signify a statement of facts alleged by way of previous explanation or introduction to other material facts. Averments which are mere inducement need not be proved so precisely as others.

Induction (Lat. *inductio*, from *duco*, *I lead*; termed in Greek philosophy, *επαγωγή*). The counter-process in scientific method to *deduction*, implies the raising individuals into generals, and those into still higher generalities; deduction being the *bringing down* of universals to lower genera or to individuals. Every deduction, therefore, to be valid, must rest on a prior induction, which, in order that we may obtain logical certainty, must be a *complete* induction: that is to say, must include *all* the individuals which constitute the genus. This, it is evident, is impossible, so long as we assume the only power necessary to induction to be the observation of particulars; for these are infinite in number; we can never be sure that we have observed them all. We are therefore compelled, if we are to admit the possibility of science properly so called, to allow the necessity of some spontaneous action of the understanding in every inductive process; of a faculty, in short, which takes occasion from experience to arrive at the knowledge of truths not contained in that experience. Philosophers differ widely in the language under which they convey their belief of this truth. Had the thing itself, however, been more distinctly borne in mind, we should have been saved much useless obscurity; in particular, we should have escaped that altogether futile distinction made by logicians between 'perfect and imperfect induction.' All the certainty that can be obtained in physics is a hypothetical certainty, founded on our belief that the course of nature is uniform; but the form of our reasoning, which is all that the logician contemplates, remains the same whether the certainty be real or assumed. Speaking generally, we may ascribe the development of all modern science to the employment of the

INDULGENCE

inductive method, which refuses to admit any fact or accept any statement or mere authority, and declines all evidence except that of actual experiment or observation, all ancient systems of philosophy having followed the deductive method, i. e. reasoning from a preconceived theory with which phenomena must be made to fit. (Playfair, *Introd. Essay to the Ency. Brit.*; Hallam, *On the Literature of Europe*, vol. iii.; Mill, *System of Logic*.) [LOGIC.]

INDUCTION. In Ecclesiastical Law, the admission of a clerk presented to a benefice to the temporalities thereof. The archdeacon has of common right the power to induct: other officers, in some cases, by prescription; or by the bishop's appointment. The form of induction is by introducing the incumbent within the door of the church. [INSITUATION.]

Induction, Electrical. A body charged with electricity disturbs the electrical condition of all surrounding bodies; thus, if a sphere A, charged with positive electricity, be brought

near a metallic cylinder B, the latter becomes *electropolar*, its negative electricity being attracted to the end of the cylinder nearest A, whilst its positive electricity is repelled to the opposite extremity. This action of an electrified body upon surrounding matter, unconnected with it by a conductor, is termed *induction*. [ELECTRICITY.]

Induction, Mathematical. A peculiar method of demonstration frequently employed in establishing the general truth of a proposition which is known to be true in one or more particular cases. To illustrate the process, let it be required to show that $x^n - y^n$ is exactly divisible by $x - y$ for all integral values of n . From the identity

$$x^{n+1} - y^{n+1} = (x^n - y^n)x + (x - y)y^n$$

we at once conclude that if the proposition were true for any one integral value of n , it would be true for the next higher value $n + 1$; but it is manifestly true for $n = 1$; hence, by *successive induction*, it holds for $n = 2, 3, 4$, &c., . . . in short, for all integral values of the exponent.

Indulgence (Lat. *indulgentia*). A power claimed by the Roman Catholic church of granting remission for a certain term, either on earth or in purgatory, of the penalty due to sin. The practice was first instituted in the eleventh century by Popes Gregory VII., Victor, and Urban II., as a recompense to those who embarked in the perilous enterprise of the Crusades; but its benefits in process of time extended to all who, either by donations or other services, contributed to the well-being of the church. The profligate sale of indulgences first excited Luther to commence his warfare against the see of Rome; and although the traffic in indulgences has been reprobated by many councils, and some minor corruptions

INDULT

have been partially reformed, still the council of Trent decreed the usefulness and validity of such instruments, and left the whole control of their nature and manner of issuing them entirely in the discretion of the pope for the time being.

Indult (Lat. *indultus*, part. of *indulgeo*, *I indulge*). In Ecclesiastical Law, a peculiar form of dispensation from requirements of the ordinary law, granted by the pope.

Indumentum (Lat. from *induo*, *I put on*). In Zoology, the term is restricted in its signification to the plumage of birds. This consists of the peculiar epidermic organs called *feathers* and *down*, with sometimes a scanty admixture of hair. [FAATREZA.] The plumage is generally more than once changed before it attains that state which is characteristic of the fully mature bird. The period during which these mutations are proceeding varies from one to five years, and many birds rear a progeny before they acquire the plumage of maturity. When the indumentum of the male bird differs in colour from that of the female, the young birds of both sexes resemble the latter in their first plumage; but when both the adult male and female are of the same colour, the young have then a plumage peculiar to themselves. In some species the adult birds have a plumage during the breeding season decidedly different in colour from that which they bear in winter: in these cases the young birds differ in colour from both parents, and have a plumage which is intermediate in its general tone to that of the two periodical states of the parent birds, and bearing indications of the colours to be afterwards attained at either period.

The changes in the colour of the plumage of birds are effected either by a total moult of the old and the acquisition of new feathers; or by a partial moult, and the admixture of new feathers with a certain proportion of the previous plumage; or on the bird's obtaining a certain number of new feathers without shedding any of the old ones; or, lastly, by the fully formed feather itself becoming altered in colour. The last two changes take place in the adult birds at the approach of the breeding season. The change of colour of a fully developed feather is produced either mechanically by the wearing away of the lighter coloured tips, which exposes the brighter tints of the plumage beneath, or by some internal chemical or vital influence upon the colouring matter of the feather itself: the latter change begins at that part of the web nearest the body of the bird, and gradually extends outwards till it pervades the whole feather.

Indus. In Astronomy, the Indian, one of the constellations.

Indusial Limestone. A fresh-water limestone found in Auvergne, abounding in the *indusæ* or cases of the larvæ of *Phryganea*, great heaps of which have been incrustated by hard travertin and formed into rock.

Indusium (Lat. from *induo*). In Botany, the cup that surrounds the stigma of Good-

INERTIA, MOMENT OF

niaceous and some other plants. Also the name of the membrane that covers the thecae or spore-cases in Dorsiferous ferns.

Induvies (Lat.). In Botany, the withered remains of leaves which, not being articulated with the stem, cannot fall off; the part covered by them is said to be *induviate*.

Inequality. In Astronomy, this term is applied to any deviation in the motion of a planet or satellite from its uniform mean motion. The great inequality of Saturn and Jupiter is a variation in the orbital motions of these planets caused by their mutual attractions.

The moon's parallactic inequality is one of great interest, as from it the sun's distance can be determined.

Inertes (Lat. *iners*, *slotful*). The name of an order of birds in the ornithological system of Temminck, including the *dodo* and *apteryx*.

Inertia. (Lat. from *iners*). This term is used to denote the principle or law of the material world, that all bodies are absolutely passive or indifferent to a state of rest or motion, and would continue for ever at rest, or persevere in the same uniform and rectilinear motion, unless disturbed by the action of some extrinsic force. The ancients attributed to matter a certain inaptitude or reluctance to motion; but that a body in motion required the operation of an extrinsic cause to bring it to rest was first stated by Galileo. Kepler, conceiving the disposition of a body to maintain its motion as indicating an exertion of power, prefixed the word *vis*; and the compound expression, *vis inertiae*, though less accurate, has been generally retained. Inertia is one of the inherent properties of matter, and unceasingly recalled to our observation in every incident of life.

Inertia, Moment of. In Mechanics, the sum of the products of the masses of the particles of a body into the squares of their respective distances from a given axis is called the *moment of inertia* of the body with respect to that axis. Thus if dm denote the element of mass, and r the distance of this element from the axis, the

moment of inertia will be $\int r^2 dm$, if the integration be extended to all particles of the body. If we denote by $M = \int dm$ the whole mass of the body, and determine k so that $Mk^2 = \int r^2 dm$, then k is termed the *radius of gyration* or *arm of inertia*; it is the distance from the axis at which a material particle, whose mass is equal to that of the body, must be placed in order to have the same moment of inertia. The *principal moments of inertia* with reference to any point of a body are its moments of inertia with respect to the principal axes passing through that point. Calling them A, B, and C respectively, and denoting by H the moment of inertia with respect to any other axis through the same

INESCUTCHEON

point, inclined to the principal axes at the angles α , β , γ , respectively, then

$$H = A \cos^2 \alpha + B \cos^2 \beta + C \cos^2 \gamma.$$

The rotation axes for which H is constant are clearly the generators of a quadric cone called the *equimomental cone*. If H_0 represent the moment of inertia about an axis passing through the centre of gravity and parallel to that which corresponds to H , and h denote the distance between the two axes, then

$$H = H_0 + M h^2,$$

so that of all parallel axes the moment of inertia is the least for that which passes through the centre of gravity, and it is the same for all parallel axes which are equidistant from that centre. Knowing the principal moments of inertia, A_0 , B_0 , C_0 , with respect to the centre of gravity, therefore, the moment of inertia with respect to any axis whatever is given by the formula

$$H = A_0 \cos^2 \alpha + B_0 \cos^2 \beta + C_0 \cos^2 \gamma + M h^2.$$

The ellipsoid whose centre is at any point O , whose semi-axes have the same directions as the principal axes, and are inversely proportional to the principal radii of gyration at O , is called the *momental ellipsoid* at that point, or the *central momental ellipsoid* if the point O coincides with the centre of gravity. The

of each radius vector of a momental is inversely proportional to the moment of inertia relative to that radius vector as axis of rotation. The polar reciprocal, with respect to a certain concentric sphere, of a momental ellipsoid is termed an *ellipsoid of gyration*; it is coaxial with the momental ellipsoid, and has the principal radii of gyration for semi-axes. The radii vectors of the central pedal of this ellipsoid of gyration are precisely equal to the radii of gyration relative to axes of rotation which coincide with the said vectors.

The above equimomental cone is not to be confounded with what Prof. W. Thomson has called the *equimomental surface* (*Cambridge and Dublin Mathematical Journal*, vol. i.). This is the locus of all points at which one of the principal moments of inertia has a given constant value, $H = M k^2$. It is a surface of the 6th order whose equation is

$$\frac{y^2}{r^2 + a^2 - k^2} - \frac{y^2}{r^2 + b^2 - k^2} + \frac{y^2}{r^2 + c^2 - k^2} = 1,$$

where a , b , c are the principal radii of gyration, and

$$r^2 = x^2 + y^2 + z^2.$$

Inescutcheon (Lat. *scutum*, a shield). In Heraldry, a species of ordinary, being an escutcheon placed upon the fess point [Fess]; and containing, it is said, the third part when charged, the fifth when otherwise. All escutcheons borne within escutcheons are by some heralds called by this name.

INFANTE

Infallibility (Lat. *in*, neg., and *fallo*, I deceive). This attribute is claimed by the church of Rome in matters of faith, but denied by Protestants. The church of England declares in her 19th Article: 'As the church of Jerusalem, Alexandria, and Antioch have erred, so also the church of Rome hath erred, not only in their living and manner of ceremonies, but also in matters of faith.' Among the Roman Catholics themselves there is a difference of opinion as to where this presumed infallibility rests, whether in the pope himself or in general councils.

Infant (Lat. *infans*, literally *speechless*, like the Greek *ἄφωνος*). In Law, a person under twenty-one years of age. He is not considered in law as having sufficient ability to contract, and is protected from his own improvidence and the artifices of designing persons by his not being liable for any engagements into which he may have entered, except for necessities suited to his condition in life. Of his contracts, however, many are not absolutely void, but only voidable; and though they cannot be enforced against him, yet he may, if he do not choose to avoid them, enforce them against another, and may always confirm them on the termination of his minority. He is in general responsible in damages for torts committed by him, as for slander, or assault. His responsibility for crimes varies according to his age and discretion: under seven years of age he cannot be guilty of felony; between seven and fourteen a presumption arises that he is *doli incapax*; but this presumption may be repelled by proof that he could plainly distinguish between good and evil, and he may then suffer death as a felon; and after fourteen he is in general as amenable to punishment as a person of full age.

His disabilities, many of which are in the nature of privileges, and established for his protection, are numerous: he cannot fill any office connected with the administration of justice, or sit in parliament; he cannot be an executor, nor appear in court by attorney. The consent of parents or guardians, or of the Court of Chancery, is requisite to his marriage.

Infant Baptism. The practice of baptising infants, adopted from early Christian usage, with the presumed warrant of Scripture (St. Mark x. 13), by the Roman Catholic, the Greek, Anglican, and by the greater number of Protestant churches. It is rejected by the Baptists, more properly called Anti-pedobaptists. [ANABAPTISTS.]

Infante, Infanta. The titles borne by the younger sons and the daughters of a king of Spain, the eldest son being styled Prince of Asturias. It is found in a document of the year 999, applied to the sons of King Vermont II. It appears, however, to have been anciently given to all hidalgos. (*Quart. Rev.* vol. lxii. p. 104, where the reader is referred to the '*Ley de Partidas*' 1, 2.) The word *childe* was similarly used in England in the middle ages.

INFANTICIDE

Infanticide or **Child-murder**. By the law of England, infanticide is placed upon the same footing with other homicide. By 24 & 25 Vict. c. 100, a person indicted for the murder of a child may, if acquitted of the murder, be convicted of the misdemeanour of secreting the body of the child to conceal its birth. To administer poison, or use other means to procure the miscarriage of a woman great with child, is also a felony by the same statute (c. 59). The exposure of new-born infants, particularly females, is a common practice among many savage nations at the present day, and especially prevalent among the Chinese. According to Lord Macartney, the number of infanticides committed in Pekin alone exceeds 20,000 a year. In some countries polyandry is the result of this practice.

Infantry (Lat. *infans*, used in the middle ages in the sense of *boy* or *servant*: as during the middle ages servants went on foot, while the knights rode on horseback, *infanteria* became the name of foot soldiers in general). Among the ancient Greeks and Romans, the infantry constituted the chief strength of an army; and, with the exception of that period in European history during which the institutions of chivalry prevailed, when the tournament with its gay appendages engaged the attention of all the powerful nobles, and thus imparted to the *cavalry* a factitious importance, it has generally been regarded as the principal military arm. Since the institution of standing armies this has been peculiarly the case. From the period of the Conquest down to the reign of Henry VIII. the infantry of this country consisted of the inferior vassals of the feudal tenants, and from the cause above referred to was neglected both in discipline and accoutrements; but the connection of that monarch with Charles V. of Germany and Francis I. of France, whose rivalry in arms had introduced great improvements into this arm, was the means of directing attention to the defects of the English infantry, and paved the way for the introduction of that system of discipline which after the lapse of three centuries has now brought it to perfection. The infantry of the British army comprises, exclusively of the native Indian troops, 3 regiments of guards, 109 regiments of the line, a rifle brigade, and 11 colonial regiments and corps. Of the regiments of the line 83 have each 1 battalion, 25 have 2 battalions, and the 60th and rifle brigade 4 battalions each, in all 141 battalions, of which 8 are rifles and 12 Highland. There are 11 battalions of light infantry, and 9 of fusiliers. The last 9 regiments are formed from the troops of the late East India Company. [ARMY.]

Infection. [CONTAGION.]

Infestment. [INFESTATION.]

Inferise (Lat.). Sacrifices offered by the Greeks and Romans to the *Dii Manes*, or the souls of deceased heroes, or any person whose memory was held in veneration. These sacrifices consisted of almost every kind of offering,

INFINITE

and were instituted on the ninth and thirtieth days after interment.

Inferior (Lat.). In Botany, a term given to a calyx distinct from the ovary, as in *Silene*; or to an ovary which adheres to the calyx, as in the myrtle. It is, in Dr. Lindley's judgment, a bad expression, though commonly employed; the French school have substituted for it the words *nonadherent* and *adherent*.

Inferior Oolite. A fine and useful series of strata containing beds of freestone of oolitic structure, much worked at Dundry and other places near Bristol, and also near Cheltenham, and forming part of the lower division of the Oolitic series of England, is recognised by English geologists under this name. The beds pass downwards into the Lias, and the intermediate deposit is often sandy. The Inferior Oolite is separated from the Great Oolite, which contains much better freestone, by the *Fuller's earth* and *Stonesfield slate*.

The Inferior Oolite is a local subdivision, not important out of England, though recognisable in Normandy. Several species of shells, chiefly bivalves, are regarded as locally characteristic of it. Although the Inferior Oolite is separated from the Lias by the Dundry beds already mentioned, the fossils seem to vary in little more than the inevitable difference between clays and limestones. [OOLITE, GREAT.]

Infero-branchiata (Lat. *inferus*, lower; Gr. *ὑπὸ γλίσσης*, *gills*). An order of Gastropods, characterised by the position of the gills, which are situated beneath the produced margin of the mantle; they consist of two long series of leaf-shaped vascular organs. This order comprehends, in the system of Cuvier, two genera, *Phyllidia* and *Diphyllidia*.

Infodation. In Feudal Law, the placing in possession of a fee or freehold estate. [FIEF.] In English Law, the term was sometimes used to designate the granting of tithes to laymen.

Infinite and Infinitesimal (Lat. *infinitus*, *not bounded*). An infinite quantity denotes one which is greater than any assignable quantity; an infinitesimal quantity, one whose magnitude is less than that of any assignable quantity. The greater the number of parts into which a finite magnitude is divided, and the less each part becomes, the process of division being conceived to be continued indefinitely, we say that the magnitude consists of an infinite number of infinitesimal elements. Proper precautions being taken, this convention leads to no erroneous results, and greatly simplifies our enunciations. The precautions consist in carefully observing the manner in which a proposed quantity may become infinite or infinitesimal; for the ratio of two magnitudes, each of which is infinite or infinitesimal, in the above sense, may be either finite, infinite, or infinitesimal. Thus the sine and tangent of an angle both diminish as the angle diminishes, and approach a ratio of equality. The sine and versed sine also diminish, individually, as the angle diminishes, but

INFINITIVE MOOD

the ratio of the first to the second increases under the same circumstances, and finally needs any assignable ratio, in other words becomes infinite. We are thus led to the consideration of infinities and infinitesimals of *different orders*. The evanescent versed sine would be said to be an infinitesimal of the *second order* in comparison with the infinitely small sine. The symbols for infinitely great and small quantities are ∞ and 0 ; and from the above remarks it will be at once seen in what manner we must interpret such expres-

sions as $\frac{a}{0} = \infty$ and $\frac{a}{\infty} = 0$, where a denotes a finite magnitude; as also in what sense 0 and ∞ , 0^∞ &c. are indeterminate. With re-

ference to these symbols, it must be borne in mind also, that whereas we have an *absolute zero*, when one of two equal magnitudes is subtracted from the other, we have no *absolute infinity*.

The *infinitesimal calculus* is simply the differential calculus propounded, in Leibnitz's manner, according to the theory of infinitesimals. The geometrical method of infinitesimals is another application of the same principles, and is of the greatest utility. Curves are therein considered, as polygons possessing an infinite number of infinitesimal sides. The term *infinity* occurs frequently in modern geometrical phraseology, and when properly understood is not only convenient, but advantageous, through the uniformity of enunciation which is thereby secured.

Thus two parallel right lines are said to intersect in an infinitely distant point, in order that they may be included in the general law. The infinitely distant points of a plane are considered as situated in a right line, *the line at infinity* or intersection of any two parallel planes. Again, the infinitely distant points of space may be regarded as situated in the *plane at infinity*, and so on.

The metaphysical difficulties inseparable from the present subject are ably discussed in a paper by Prof. de Morgan (*Transactions of the Cambridge Philosophical Society*, vol. xi. part i.).

Infinitive Mood. In Grammar, that inflexion of the verb which expresses the conception merely, without affirming or denying it, of any subject. [GRAMMAR.]

Infirmary (Lat. *infirmus*, weak). An hospital for the reception of the sick poor, either supported by the public, or endowed by benevolent persons with funds to defray the necessary expense. Establishments bearing this name are not uncommon in all considerable towns of the British empire. [HOSPITAL.]

Inflammation (Lat. *inflammatio*, an *inflaming*). In Pathology, this term is applied to redness and heat of some part of the body, attended by pain and swelling: the vascular action of the part being increased. Inflammation terminates either in *resolution*, *sup-*

INFLLEXIONAL TANGENTS

uration, *ulceration*, or *gangrene*, according to the constitution of the patient and the nature of the cause which gave rise to it.

Inflexed (Lat. *inflexus*, part. of *infecto*, *I bend*). In Zoology, when a part is bent inwards.

Inflexion (Lat. *inflexio*, a *bending*). In Grammar, that process which modifies declinable words in languages where the pronominal and predicative roots may be so combined as to form one word. This cannot take place in radical or monosyllabic languages like the Chinese, or the agglutinate languages of the Turanian family. Hence, the Semitic and Aryan tongues are called *inflexional*. Thus in the Latin future *amabo*, or the Greek future *τιν-σ-ω* (*τινίσω*), the inflexion is supplied by the auxiliary verb *bhu*, to be, and *as*, to be, while the termination, which is pronominal, varies according to the person; *amabo*, *amabis*, *amabit*, &c. [GRAMMAR; FUTURE TENSE; IMPERFECT TENSE; &c.]

INFLXION. In Optics, the same as *diffraction*; or that property of light by reason of which, when it passes very near the borders of an opaque body, it is turned from its rectilinear course. [DIFFRACTION and LIGHT.]

Inflexion, Point of. In Geometry, the point of contact of a stationary tangent; that is to say, a point at which the curve passes from one to the other side of its tangent, and towards which it always turns its convexity. It is sometimes called a point of contrary flexure. The points of inflexion of a curve are always situated on its Hessian, which is another curve of the $3(n-2)^{th}$ order, so that in general there are $3n(n-2)$ such points on a curve of the n^{th} order. Should the latter possess double points, however, this number will be diminished. [STATIONARY TANGENT and SINGULARITIES OF A CURVE.]

The term *point of inflexion*, in an extended sense, indicates any point at which the tangent meets the curve in an odd number of consecutive points, since under such circumstances the curve will always pass from one to the other side of the tangent. When the tangent has four or any higher even number of consecutive points in common with the curve, the latter does not pass to the other side, and the point is distinguished as a *point of undulation*.

Inflexional Tangents. In the theory of surfaces, the two lines, each of which, at their intersection, meets the surface in three consecutive points. They are imaginary, real, or coincident, according as the point is an elliptic, hyperbolic, or parabolic one. They coincide, in fact, with the asymptotes of the indicatrix, and each represents a pair of coincident conjugate tangents. [INDICATRIX.] The term *inflexional tangent* appears to have been first employed by Dr. Salmon in his *Analytical Geometry*, and was evidently suggested by the fact that each such tangent touches the section made by any plane through it at a point of inflexion. An inflexional tangent must be regarded as a *double tangent* line to the surface, since it joins the first to the

INFLORESCENCE

second, as well as the second to the third, of the three consecutive points coincident with that of contact. Through an arbitrary point in space there can in general be drawn $n(n-1)(n-2)$ inflexional tangents to a surface of the n^{th} order.

Inflorescence (Lat. *inflorescere*, to begin to blossom). The general arrangement of the flowers upon a stem or branch. It consists of the following principal kinds: viz. the spike, the raceme, the panicle, the capitulum, the umbel, and the cyme; each of which is mentioned in its place.

Influenza (as if produced by the *influence* of the stars). An epidemic *catarrh*, generally attended by languor, headache, quick pulse, and febrile symptoms, which often run very high, and assume a variety of aspects, dependant upon the season and other causes. The possibility of the existence of some highly poisonous and irritating vapour, though in very minute quantity, as the exciting cause of influenza, has been suggested by Dr. Prout. It may possibly be of volcanic origin; and such a substance as seleniuretted hydrogen, the effects of which, even in extremely minute quantity, are highly deleterious, might perhaps account for some of the phenomena of this extraordinary disease.

Information (Lat. *informatio*, an outline or sketch). In Law, an accusation exhibited against a defendant for some criminal offence, not on the oath of jurors, but on the special allegation of an officer empowered to exhibit it. Criminal informations are either partly at the suit of the king and partly at that of a subject, namely such as are brought upon certain penal statutes at the suit of common informers; or wholly at the suit of the king. These are of two sorts: 1. Those filed ex officio by the attorney-general—a proceeding resorted to in the case of some particular misdemeanours of a public nature, as libels and various other offences concerning the public government; and 2. Informations filed at the suit of the master of the crown office, which lie for some gross and notorious misdemeanours, as riots, batteries, libels, &c., not immediately tending to disturb the government.

Informed Stars (Lat. *Informes Stellæ*). In Astronomy, stars not included in any of the constellations. [CONSTELLATIONS.]

Infra-lapsarians (Lat. *infra*, below, and *lapsus*, a fall). In Ecclesiastical History, a sect of Presbyterians who maintain that God has created a certain number of human beings only to be damned, without allowing them the opportunity of salvation even if they chose to embrace it. They are thus designated because they hold that the decrees of God were formed *infra lapsum*, after His knowledge of the fall, and in consequence of it. [SUPRALAPSARIANS.]

Infundibuliform (Lat. *infundibulum*, a funnel). A Botanical and Anatomical term, signifying *funnel-shaped*. The *infundibulum* of the brain is a canal proceeding from the lower and anterior part of the third ventricle of the brain to the pituitary gland.

INFUSORIA

Infusoria (Lat. *infundo*, I pour in). A name applied by Otto Fr. Müller to an assemblage of microscopic animalcules which are for the most part developed in infusions of decayed animal and vegetable substances. Some of these minute organised beings were known to Linnæus, and were placed by him at the end of the class *Vermes*, in a genus which he denominated *Chaos*. Müller, who made the Infusoria a subject of special study, discovered numerous distinct genera and species, which he named and classified according to their outward form. Gmelin and Lamarck introduced Müller's discoveries and classification of the Infusoria into their systems without any particular modification. Cuvier, in 1829, observes, that 'Naturalists usually close the catalogue of the animal kingdom with beings so extremely minute as to be invisible to the naked eye, and which have been discovered only since the invention of the microscope has unveiled to us, as it were, a new world. Most of them present a gelatinous body of the greatest simplicity, and for these this is undoubtedly the situation; but authors have placed among the Infusoria animals apparently much more complicated, and which only resemble them in their minuteness and the dwelling in which they are usually found.' These higher-organised Infusoria were placed by Cuvier at the head of the class in a distinct order, under the name of *Rotifera*, a name which has subsequently been retained. Cuvier attributes to these animalcules a mouth, a stomach, an intestine, and an anus; and notices the prominences on the anterior part of the body, which some observers had regarded as eyes. The anterior lobated organ and its vibratory denticulations, the successive action of which gives to the organ the appearance of a swiftly rotating wheel, forms the main external character of the order. Cuvier includes in the order *Rotatoria* the genera *Furcularia*, Lam.; *Vaginicola*, Lam.; *Tubicolaria*, Lam.; *Brachionus*, Müller.

The investigations of Ehrenberg, with the aid of a microscope superior to that of his predecessors, have brought to light many additional organs and complexities of structure in the *Rotifera*, besides several genera and species before unknown; and since these researches naturalists have generally regarded the *Rotifera* as a distinct class of Invertebrata, which Professor Grant has placed in the Articulate sub-kingdom, and Professor Owen in the *Nemato-neura*, or higher division of Cuvier's *Radiata*. For the character, subdivision, and organisation of the *Rotifera*, see that word.

The second order of Infusoria in Cuvier's system is denominated *Homogenea*; a term sufficiently expressing the inadequate ideas current at that recent period respecting their organisation. Cuvier says, 'The body of the *Homogenea* presents neither viscera nor other complication, and is frequently destitute of even the appearance of a mouth.' Ehrenberg has since shown not only that they have really a mouth, but that the greater part of the

INGA

Homogœna of Cuvier possess a digestive cavity complicated with many cœcal cavities like stomachs; and accordingly proposes to name the order *Polygastrica*. True Infusoria of this class have, internally, a part called *nucleus* and a *contractile vesicle*; they are externally provided with vibratile cilia. Cuvier includes in his second order of Infusoria the genera *Urceolaria*, Lam.; *Trichoda*, *Leucophra*, *Kerona*, *Himantopus*, *Cercaria*, *Furcocerca*, *Vibrio*, *Proteus*, *Volvox*, and *Monas*. As the polygastric structure has not been detected in any species of *Cercaria*, but as, on the contrary, some species, as *Cercaria lemnae*, possess a simple alimentary canal, this genus, together with the *Vibronidae*, which all possess a straight and simple alimentary canal, have been removed from the Infusoria, and classed by Professor Owen with the lower *Vermes*, including the Entozoa.

Thus the animals of infusions, although of comparatively simple organisation, yet manifest at least three distinct types of structure, and are referable to three different classes of animals; many, moreover, have been proved to be embryos of algæ.

Many genera of Infusoria are protected by an external silicious case. The observations which Ehrenberg had made on the modifications of the form and surface of these cases of the existing Infusoria led to his capital discovery of their remains in a fossilised state. The mineral called *Polier-scheifer*, used for a long period in the arts for polishing metals and other substances, was first discovered to be composed of myriads of the microscopic flinty cases of polygastric Infusoria belonging to the genera *Gaillonella*, *Bacillaria*, *Diatoma*, &c. Whole strata of considerable extent and thickness have since been found to consist almost exclusively of the fossil remains of Infusoria.

Inga (the South American name for one of the species). A Leguminous genus of South American trees belonging to the suborder *Casalpinia*. They have pinnated leaves, and in many cases handsome flowers. The white pulp contained in the pods of *I. Feuilletii* is eaten in Peru, as is that of *I. spectabilis* and others in Panama; while that of the West Indian *I. vera* is purgative.

Ingluvies (Lat. *a crop*). The crop or dilatation of the œsophagus, in which the food is accumulated and macerated, but not digested. It is largest in the Gallinaceous birds and pigeons, but exists in certain birds of prey: also in the flamingo, and others.

Ingot. A word of doubtful origin, signifying chiefly the small masses or bars of gold and silver intended either for coining or exportation.

Ingrafting. [GRAFTING.]

Ingrailed. In Heraldry. [ENGRAILED.]

Ingrossing. [ENGRROSSING; FORESTALLING.]

Inguinal (Lat. *inguinalis*, from *inguen*, the groin). Appertaining to or situated in or near the groin: as *inguinal artery*, *inguinal hernia*, &c.

INHIBITION

Inhabitant (Lat. *inhabitans*, part. of *inhabito*, *I dwell in*). In Law, a word used in various technical senses. Thus a person having lands or tenements in his own possession is an inhabitant for the purpose of repair of bridges, wherever he may reside; but for purposes of personal service the *inhabitant* must necessarily be a resident. For the purpose of the poor rate, the word means a person residing permanently and sleeping in the parish. Where the right of voting was formerly in *inhabitant* householders, a variety of divisions in committees of the House of Commons, in some instances conflicting, took place on the point. But it appears to be generally understood that an inhabitant is one who keeps a house in his own occupation, either personally residing in it, or having it occupied by servants and ready for his residence; having what is termed the *animus revertendi*, or intention to return.

Inhalation (Lat. *halo*, *I breathe*). The drawing of air, gases, or vapours, into the lungs. Many substances are medicinally applied in this form, by means of an *inhaler*, an instrument so contrived as to admit of the inhalation of a variety of vapours mixed more or less with atmospheric air. The steam of hot water, the vapour of tar, of ether, of chloroform, of iodine, chlorine, &c. may be thus administered.

Inharmonical Relation. In Music, that in which a dissonant sound is introduced.

Inheritance (Lat. *heres*, *an heir*). In Law, an estate or real property which a man has to himself and his heirs, or the heirs of his body, &c., is termed a freehold of inheritance. [FEE SIMPLE; FEE TAIL.]

Inheritance, Law of. In Physiology. The law by which individuals invariably, to a certain extent, transmit their forms and peculiarities to their offspring. The existence of this law has been impugned by Mr. Buckle, but it is satisfactorily borne out within certain limits by the phenomena known to stud-masters, sheep-farmers, and pigeon-fanciers, who are able to produce almost any form designed, within the limits of the specific characters of the individual. No satisfactory theory has yet been offered to physiologists to define which are the faculties transmitted by the male and the female parents respectively to their progeny. (Prosper Lucas, *Traité sur l'Hérédité*.)

Inhibition (Lat. *inhibitio*, from *inhibeo*, *I restrain*). In Ecclesiastical Law, a writ, commonly issuing out of a higher court Christian, to forbid an inferior judge from further proceeding in a cause before him; being analogous to a prohibition issuing out of one of the king's superior courts of justice.

INHIBITION. In Scottish Law, a species of diligence: i. e. process. It is a writ in the king's name, passing under the signet, whereby a debtor is prohibited from contracting any debt which may become a burden on his heritable property in competition with the creditor at whose instance the inhibition is taken out; and

from granting any deed of alienation, &c., to the prejudice of the creditor. The heir of the debtor is not affected by the inhibition of his ancestor. Other species of inhibition are, that of a husband against his wife, intended to signify that her superintendence over domestic affairs has ceased, on which his liability for domestic expenditure contracted by her also ceases; and inhibition of tithes or teinds.

Inis (perhaps from the same root with Gr. *νῆσος*, and Lat. *insula*, an island). An Irish word signifying island, used as a prefix to the names of some islands on the coast of Ireland, and of several towns situated on lakes or rivers in the same country; as Inisfallen, Iniskilling, &c.

Initial Velocity. The velocity of a projectile at the instant after leaving the muzzle of a gun. [GUNNERY.]

Initiative (Lat. *initium*, a beginning). In Politics. In legislative assemblies constituted so as to comprise more than one chamber, or more than one distinct and coordinate power, that branch of the legislature to which belongs of right the power to propose measures of a particular class is said to have the initiative with respect to those measures. Thus in England all propositions for taxing the subject, whether directly or indirectly, must begin in the Commons; a usage which has been adopted in most modern constitutions. On the other hand, there are some private bills which by custom originate in the Lords; and one bill, that, namely, for a general pardon, is proposed in the first instance by the crown. In France, by the charter of 1830, the three branches of the constitution enjoyed like privileges in proposing laws; but custom generally conceded the initiative to the Chamber of Peers, excepting in the case of money bills, which must, as in England, originate with the Chamber of Deputies; and the same principle is preserved in the modern legislature.

Injection (Lat. *injectio*, from *injicio*, I cast in). The process of introducing a jet of cold water into the condensing chamber of a low-pressure engine, for the purpose of hastening the production of a vacuum.

INJECTION. A liquid thrown into a cavity of the body by means of a bladder, syringe, or elastic bottle. Injections thrown into the rectum are called *enemata*, or *clysters* (from Gr. *κλύειν*, I wash).

Injunction (Lat. *injunctio*). In Law, a writ which issues under the seal of a court of equity. It is defined by Story, 'a judicial process, whereby a party is required to do or to refrain from doing a particular thing, according to the exigency of the writ,' granted in various cases, where the court thinks fit to interfere on equitable grounds with the acts of parties, or with the course of other jurisdictions. Thus injunctions are granted under certain circumstances to stay proceedings at common law; to restrain the negotiation of notes and other securities; to restrain parties from the commission of waste; to preserve property which is in course of litigation, &c. Injunc-

tions are also granted to direct parties to quit possession of lands, &c. after a decree. Disobedience to an injunction is punishable as a contempt of the court from which it issues. By the Common Law Procedure Act, 1854, courts of common law were for the first time empowered to grant writs of injunction in certain cases.

Ink (Ger. Dutch ink; Fr. *encre*, perhaps from the Gr. *ἐγκύριον*: Wedgwood, s.v.). The colouring matter of common writing ink is the tannogallate of iron, which is suspended in water by gum arabic; a little logwood is sometimes added to deepen and improve the colour. A good writing ink is made as follows: Take six ounces of finely bruised galls, four ounces of gum arabic, four ounces of green vitriol, and six pints of soft water. Boil the galls in the water; then add the other ingredients; and mixing the whole well together, keep it in a well-corked bottle, occasionally shaking it. In two months' time carefully pour off the ink from the residue into glass bottles, which should be well corked; a few cloves, or a drop or two of creasote, put into each bottle, prevent moulding. The addition of a little sugar to ink gives it a gloss, and prevents its drying rapidly and perfectly; so that it is generally used in what is called *copying ink*. *Indian ink* is a compound of very fine lampblack and size. It cannot, like common writing, be removed by acids; but as it does not bite or sink into the paper, it may generally be wiped off with a moist sponge. *Printing ink* is made with boiled linseed or nut oil and lampblack. *Red ink* is a solution of alum coloured with brazil wood. Boil two ounces of brazil wood, half an ounce of gum arabic, and a quarter of an ounce of alum in a pint of water for ten minutes; strain the decoction, and set it aside to clear. Ammoniacal solutions of cochineal are also used as *red inks*. *Sym pathetic inks* are compounds which, when written with, will remain invisible till heated: solutions of cobalt thus become blue or green; lemon juice turns brown; and a very dilute sulphuric acid blackens. *Marking ink* is made as follows: Dissolve one drachm of lunar caustic (fused nitrate of silver) in half an ounce of water previously thickened with a little sap green: write with this upon the linen previously prepared for its reception by the application of a weak solution of carbonate of soda thickened with a little gum arabic, and suffered to dry upon the linen. A good marking ink requiring no preparatory application may be made as follows: Take nitrate of silver and bitartrate of potash, of each one ounce; solution of ammonia, four ounces; archil, half an ounce; honey, three drachms; compound tragacanth powder, one drachm and a half. Rub the nitrate of silver and the tartar together, and then add the other ingredients. Linen marked with this ink requires to have a hot iron passed over it; or the part marked may be held to the fire till the marks blacken. (Gray's *Supplement to the Pharmacopœia*.)

INLAND SEAS

Inland Seas. In various parts of the world there are large tracts of water enclosed or nearly enclosed by land, and only communicating with the sea by narrow channels called *straits*. When the communication with the ocean is somewhat wider than deserves the name of strait, the sea is generally called a **GULF**, and when very wide indeed it becomes a **BAY**. When the waters are so nearly enclosed as to communicate with the sea only by a river, they are called **LAKES**. [See those separate articles.]

Of all inland seas, properly so called, the **MEDITERRANEAN** is the most important, and the **BALTIC** comes next. The **CARIBBEAN SEA** is indeed larger than either, but it is less completely detached. All these are described separately. The **BLACK SEA** and the **CASPIAN** are remarkable, but the former is a sea within a sea, and the latter a lake. The Sea of Okhotsk, between North-eastern Asia and the Kurile Islands; the Sea of Japan, between the Asiatic coasts and the islands of Japan; the Yellow Sea and the China Sea, also on the same coast, are examples more or less striking of the same semi-enclosed pieces of water. The **RED SEA** is a singular strip of enclosed water, and is described in a separate article.

Innocents' Day. In the Calendar, a festival celebrated on the 28th of December, in commemoration of the infants stated in the Gospel of St. Matthew to have been murdered by Herod the Great.

Innominate (Lat. in, neg., and nomen, a name; without a name). Each of the lateral bones of the pelvis is called *os innominatum*; because the three bones of which it consists originally, namely the *ischium*, the *ilium*, and the *pubis*, or the hip bone, the haunch bone, and the share bone, grow afterwards together so as to form what appears to be a single bone, which is thus left nameless.

Inns of Court. Four collegiate societies established in London. Every candidate for the rank of barrister-at-law is obliged to be admitted a member of one of these societies, and submit to its regulations as a student. These are: 1. The Inner Temple; 2. The Middle Temple; 3. Lincoln's Inn; 4. Gray's Inn. They are governed by **BENCHERS**. The *Inns of Chancery* (Clifford's, Lyons, Clement's, New, Furnival's, Thavies, Staples, and Barnard's Inns) were formerly subordinate societies depending on the Inns of Court, but this connection is now obsolete.

Innuendo (Lat. innuo, I nod or beckon). In Law. In the old Latin forms of pleadings this term was used as a word of reference, when in relating the words of another party it was necessary to describe more particularly the person or thing meant by that party; as, for instance, in a declaration in action for slander, which is the most ordinary modern case of the employment of the innuendo, the plaintiff avers that the defendant said that *he*, innuendo (meaning the plaintiff), was a thief, &c. Hence

INOCULATION OF GRASS LANDS

the use of the word, *an innuendo*, in ordinary language to signify a covert allusion.

Inocarpus (Gr. *is*, *ivós*, a fibre, and *καρπός*, fruit). A Leguminous tree, belonging to the group *Cesalpinieæ*. The seeds of *I. edulis* are eaten, and much prized by the natives of the Indian Archipelago; they are sweetish when boiled or roasted in ashes, but are not a very wholesome or palatable food.

Inoculation (Lat. in, and oculus, an eye). The introduction into the blood of a specific animal poison either by puncture or by contact with an already wounded surface. The term is generally used in reference to the various or smallpox poison. It is equally applicable, however, in speaking of the matter of glanders, or of that which occasionally enters the circulation owing to punctures received while dissecting the bodies of those who have perished from certain peculiar forms of disease. Inoculation by the vaccine virus is termed *vaccination*. It is said that inoculation by the smallpox virus was first practised by the Circassians, who adopted it as a means of preserving their women from the ravages of a disease so calculated to destroy beauty. Some believe that Lady Wortley Montague introduced inoculation into Britain from Turkey in 1721, her son having been inoculated at Constantinople.

Much has been written on the advantages of inoculation as a means of preserving life. It has been calculated that in severe epidemics one-third of the adults attacked die, and one-seventh of the children; whereas, if inoculation be practised and the patient carefully treated, only 1 in 500 or 600 perish. Vaccination has now superseded inoculation; and the legislature is so persuaded of the advantages of the former, that inoculation is punishable by law, while vaccination is compulsory. [COWPOX; VACCINATION.]

Inoculation of Grass Lands. The ordinary method of turning a ploughed field into a meadow or pasture is by sowing it with grass seeds; but as this part of agriculture was formerly very ill understood, and the result of sowing grass seeds failed frequently to answer the expectations of the sower, the practice of what is called *inoculation* has of late years been invented, though practised but in very few instances. This consists in preparing the soil as if it were to be sown down with grass seeds; but instead of sowing these on the surface, there are distributed over it small fragments of turf taken from the best old pasture land which the neighbourhood affords. These fragments may be about two or three inches square, and they are laid down on the surface at the rate of about one in every square foot. After they are deposited, grass seeds, mixed with clover, are scattered over the surface, and the field is rolled to press down the turf and press in the seeds. In consequence of the fragments of turf being placed on fresh soil, the grasses, and other vegetables which they contain, if of the creeping kind, grow luxuriantly, and their stems cover the intervals between the fragments; but if the grasses

INOSCULATION

which the fragments contain should not be of the creeping or stoloniferous kinds, it is evident that the intervals between them must chiefly depend for their grassy surface on the seeds which have been sown. On the whole, the inoculation of grass land may be considered as a needlessly expensive process, unsuitable to the present advanced state of agriculture.

Inosculation (Lat. in, and osculatio, *a kissing*). The union of vessels by conjunction of their extremities. This term is sometimes limited to the communication of trunks or large vessels with each other; and where the ramifications which unite are small or capillary, the vessels are said to *anastomose*.

Inosic Acid. An acid found by Liebig in the juices of the flesh of animals.

Inquest (from Lat. inquirō, *I search into*). In Law, an inquisition of jurors in causes, civil or criminal, when the facts are referred to their trial, being impanelled by the sheriff for that purpose. Also the persons to whom the trial of fact in any question, civil or criminal, is committed. An inquest of office, or inquisition, is an inquiry made by the king's officer, sheriff, coroner, &c., by virtue of their office, or by writ sent them for that purpose, or by persons acting under a special commission, to inquire concerning any matter which entitles the king to the possession of lands and tenements, or goods and chattels; as forfeiture for offences, wreck, treasure-trove, &c. The king's title in general commences on office found, i. e. after the inquest has declared the results of its investigations.

Inquisition (Lat. inquisitio, *a seeking for*). The title given to a court armed with extensive criminal authority in various European countries; especially instituted to inquire into offences against the established religion. The first of these tribunals of faith was established in the south of France after the conquest of the Albigeois in the thirteenth century. They were established in Spain in the middle of the same century, not without much opposition on the part of the bishops and secular clergy, who, in Castile, long maintained their exclusive spiritual jurisdiction. In 1484, the supreme general inquisition was founded at Seville by Queen Isabella, with the aid of the Cardinal Pedro Gonzalez de Mendoza. This great court, commonly known by the name of the Holy Office, had far more extensive authority than those local tribunals of the same name, which had previously been established. Thomas de Torquemada, prior of a Dominican convent, was its first president, with the title of inquisitor-general. The process of the inquisition was widely different from that of all other courts of justice. The king named the grand inquisitor, who appointed his assessors, some of whom were secular, but the greater part regular ecclesiastics: the counsellors were six or seven in number, of whom one, by the ordinance of Philip III., must be a Dominican. A party who was brought under cognizance of the court by secret accusation

INSANITY

was immediately seized by its officers (termed *officials* or *familiars*), and his property put under sequestration. If the accused was fortunate enough to absent himself, and did not appear at the third summons, he was excommunicated, and in some cases burnt in effigy. The subsequent process of the court by imprisonment, secret examination, and torture, is well known. Penitent offenders were subjected to imprisonment, scourging, confiscation, and legal infamy. Persons convicted and sentenced to death were burnt at the autos da fé, which usually took place on some Sunday between Trinity and Advent. According to a common calculation, 340,000 persons were punished by the inquisition from 1481 to 1808, of whom nearly 32,000 were burnt. In 1808 it was abolished by Napoleon. It was afterwards re-established by Ferdinand III. in 1814; but having been again abrogated by the cortes in 1820, it has not been since reconstituted. In Portugal, the supreme court of inquisition was established in 1557. Its history in many respects resembles that of the Spanish court; but in the eighteenth century its power was greatly curtailed by ordinances which required a certain degree of publicity in its procedure. It was abolished by the cortes of 1821. There were courts of inquisition in various southern provinces of France, the principal that of Languedoc, established at Toulouse, which was first founded after the war against the Albigeois; but their power was limited not long after their creation, and fell into desuetude long before their final abolition. At Rome the inquisition was only established in 1542 as a congregation of cardinals, styled of the *holy office*; but the other courts of inquisition throughout the Catholic world became subject to this body. Its authority was never recognised in France, and formally denied by arrêts du parlement in 1719 on the occasion of the constitution *Unigenitus*. In Italy itself the institution never took much hold on the manners or usages of the people. The court, however, subsists at Rome chiefly in practice for the correction of ecclesiastical delinquents, but its subjects of jurisdiction are legally deemed to be, heresy, blasphemy, polygamy, sacrilege, abuse of confession, false pretences to holiness, divination and sortilege, use of prohibited books, breach of the fasts of the church, &c.

Several well-known histories of the inquisition have been published, particularly that of Limborch. The reader may also consult Mosheim vol. iii.; Prescott's *Ferdinand and Isabella*; Quart. Rev. vol. lv.; Llorente's *Hist. of the Inquisition*.

Insanity (Lat. insanitas). Unsoundness of mind. This condition has been variously described, but no very satisfactory definition has yet been given, owing most probably to the fact that all the mental phenomena observed in the disease are to be detected in some degree in a vast number of persons who cannot be regarded as insane. When, however, we meet with one

INSCRIBED FIGURES

in whom the powers of conception and of reasoning are very far removed from those of people in general, we must pronounce him insane, and this opinion will be further strengthened if with this perversion of conception and of reasoning power we can detect an uncontrollable violence of the emotional feelings, and, further, a perversion of the will, of the sensations, and of the instincts.

Pathologists and psychologists are now pretty well agreed that insanity is always connected either with some minute degeneration of brain structure, or with some still more obvious deviation from normal anatomy. Thus the relative weight of the cerebrum to the cerebellum has been shown to be less in the insane than in healthy persons. The specific gravity, too, of both the white and grey matter is increased in insanity. Again, it has been demonstrated that a very important change occurs in the substance of the brain, that a shrunken condition is gradually brought about, and that the nerve cells become degenerated, while inert matter is deposited, causing atrophy of the healthy structure. It is not possible to say more here on this very extended subject, than that the disorders of the mind have been classified variously according to the nature of the mental phenomena observed in the propensities which may have become over-excited. [LUNACY.]

Inscribed and Circumscribed Figures.

In Geometry, when the angular points of one rectilinear figure are situated in the sides of a second, the former is said to be *inscribed* in the latter, and the latter to be *circumscribed* to the former. The same relative designations are employed when one of the figures is curvilinear, it being understood that when the inscribed figure is curvilinear it must *touch all the sides* of the rectilinear one. The inscription and circumscription of figures have occupied the attention of geometers since the earliest ages. Euclid devoted his fourth book to the subject [POLYGON], and some of the most important and remarkable of modern geometrical theorems and problems have a like origin. We need only cite as examples the well-known theorems of Pascal and Brianchon with respect to a conic and its inscribed and circumscribed hexagons, and the celebrated 'porism of the inscribed and circumscribed polygon,' according to which two conics may be so related that a polygon of a given number of sides may be inscribed in the one and circumscribed to the other, no matter at what point of the circumscribing conic the construction may commence. On this subject Fuss and Mention in his *Null. de l'Acad. de St. Pé.*, Poncelet in his *Traité des Propriétés Projectives des Figures*, Steiner and Jacobi in Crelle's *Journal*, and Cayley in the *Phil. Trans.* and *Phil. Mag.* &c., as well as other writers, have published valuable researches.

Inscription (Lat. *inscriptio*). In Numismatics, words placed in the middle of the reverse side of some coins and medals. [NUMISMATICS.] For the value of inscriptions gene-

INSTALLATION

rally as his arical documents, see HISTORICAL CREDIBILITY.

Insecta. [ENTOMOLOGY.]

Insectivora (Lat. *insecta*, *insects*, and *voro*, *I devour*). The name of an order of lissen-cephalous Mammals, comprehending those which have three kinds of teeth, and live wholly or chiefly on insects; also of an order of birds in the ornithological system of Tem-minck.

Inserted Column. In Architecture, a column standing or appearing to stand partly in a wall.

Insertion (Lat. *insertio*). In Botany, a term employed to denote the manner in which one part grows out of another. It was invented at a time when the laws of vegetable structure were unknown, and it was supposed that bodies which really grow from each other were inserted into each other. Thus stamens said to be inserted into a calyx are in reality stamens that adhere to the sides of a calyx.

INSERTION. In Printing, any new matter inserted in correcting proof sheets, the caret mark (^) indicating where it is to go. If a compositor omits anything in setting, the matter omitted is called an *out*.

Insesores (Lat. from *inside*, *I sit on*). A name by which Mr. Vigors has designated his second order of birds, including the *Passeres* and *Scansores* of Cuvier; and which C. Bonaparte applies to a primary division of birds in his *Systema Vertebratorum*, including the *Passeres*, *Scansores*, and *Accipitres* of Cuvier. As the term signifies those birds which perch, it is applicable to numerous species belonging to Linnæan and Cuvierian orders not yet included by later innovations under the term of *Perchers* or *Insesores*.

Inset or Offcut. In Printing, when some kinds of books, such as those in 12mo, 24mo, &c., are sent to the bookbinder and the sheets are folded, the offcut is put into the middle of the sheet to complete the succession of paging.

Insolation (Lat. *sol*, *the sun*) or **Scorching.** A local disease of plants, attributable to exposure to too bright a light, which causes an excessively rapid evaporation, the effect of which is to kill the part in which the evaporation takes place.

Insoluble Acid. A remarkably insoluble substance derived from cuminic acid by the prolonged action of chromic acid.

Insolvency (Lat. *in*, *neg.*, and *solvo*, *I pay*). In Law, formerly, the inability of an individual not engaged in trade to pay his debts. The insolvency of a trader was called *bankruptcy*. In 1861 the consolidation of bankruptcy with insolvency was effected by statute. [BANKRUPTCY.]

Inspiration (Lat. *inspiratio*, from *in*, and *spiro*, *I breathe*). The act of drawing air into the lungs. [RESPIRATION.]

INSPIRATION. In Theology. [REVELATION.]

Installation (Low Lat. *in*, and *stallum*, *a seat*). A name applied to the ceremony of installing persons in honours or dignities; as a

INSTANT

Knight of the Garter in the chapel of St. George at Windsor; a chancellor in a university; or a dean, prebendary, or other ecclesiastical dignitary, in the stall of the cathedral to which he belongs.

Instant (Lat. *instans*, part. of *insto*, *I am present*). A part of time or duration in which no succession is perceived. There are three kinds of instants distinguished by the schoolmen; a *temporary*, a *natural*, and a *rational* instant. The first is a part of time immediately preceding another; the second is what is otherwise termed a *priority of nature*, which obtains in things subordinated in acting, as first and second causes, or causes and their effects; and the third is not any real instant, but a point which the understanding conceives to have existed before some other instant, founded on the nature of the things which caused it to be conceived.

Instantaneous Axis. In Mechanics, the locus of the points which at any instant are in a state of rest, when a body turns in any manner around a fixed point. [ROTATIONS, COMPOSITION AND RESOLUTION OF.]

Instantaneous Sliding Axis. In Mechanics, the right line along and around which a body moving with perfect freedom may, at any instant, be regarded as simultaneously sliding and rotating. It coincides with the so-called *central axis*. [ROTATIONS, COMPOSITION AND RESOLUTION OF.]

Instantiae Crucis (Low Lat.). In Philosophy, *crucial* instances or examples; a phrase invented by the fancy of Bacon. The use of crucial examples or experiments is to facilitate the process of induction. For example, A and B, two different causes, may produce a certain number of similar effects; find some effect which the one produces and the other does not, and this will point out, as the direction-post at a point where two highways meet (*crux*), which of these causes may have been in operation in any particular instance. Thus, for example, many of the symptoms of the Oriental plague are common to other diseases; but when the observer discovers the peculiar *bubo* or boil of the complaint, he has an *instantia crucis*, which directs him immediately to its discovery. (See, amongst other commentaries on Bacon, Playfair's *Introd.* and *Edin. Rev.* vol. xxxvi.)

Instinct. [REASON.]

Institute (Lat. *institutus*, part. of *instituo*, *I appoint*). The principal philosophical and literary society of France, formed in 1795 by the union of four academies. [ACADEMY.] *Institute* is applied also to several works embodying the principles of Roman law; of these the chief are those of Justinian and Gaius.

Institution. In Ecclesiastical Law, otherwise called *investiture*, is the admission of a clerk to the church to which he has been presented by the ordinary (bishop, vicar-general, &c.). After institution the church is in contemplation of law *full*; but *INDUCTION* [which see] is required to give possession of the temporalities.

INSURANCE

Institutions. In Literature, a term denoting originally a system of the elements or rules of any art or science, but signifying in a more comprehensive sense all associations formed for the improvement of society at large, or the parties immediately concerned.

Instruction, Criminal. In French Law, the technical term for the preliminary investigations and procedure at the trial of a criminal. Its management is intrusted to special officers, termed *juges d'instruction*.

Instrumental Case. In Grammar, the case which is used to express the instrument with which any act is performed. In Latin, the instrumental case is commonly called the *ablative*; in Greek it is termed the *dative*; but the two cases are really distinct. [LOCATIVE CASE.]

Instrumental Errors. Those errors which arise exclusively from want of mathematical accuracy in any instrument. Thus the flexure of a telescope tube induces an *instrumental error*.

Insulated (Lat. *insulatus*). In Architecture, a term meaning that the building to which it is applied is detached from any other. Thus, a church is said to be insulated when it adjoins no other building; as also a column is said to be insulated when standing out free from a wall.

Insulation. A body is said to be insulated which, containing a quantity of free caloric, or of the electric fluid, is surrounded by non-conductors, and the communication with other bodies thereby cut off.

Insulators. In Electricity, this term is synonymous with *non-conductors*. [ELECTRICITY.] The following substances are amongst the best insulators:—

Dry air.	Caoutchouc.
Shell lac.	Silk.
Sulphur.	Dry fur.
Resins.	Glass.
Gutta serena.	

Insurance. A contract of indemnity whereby the insurer, in consideration of a certain premium, undertakes to indemnify the insured against loss arising by the occurring of a contingent event; such as the destruction of houses by fire, the loss of ships at sea, the failure of crops through the inclemency of the seasons.

Insurance is sometimes synonymously used with *assurance*; but the latter term is now more frequently applied to one particular class of contracts, namely, those which depend on the continuance or failure of human life, while *insurance* is applied to risks of all other kinds. For the explanation of the principles on which life assurances are calculated, see *ASSURANCE*.

In all cases of insurance, the first thing to be determined is the degree of probability that the event under consideration will take place; but it seldom if ever happens that this is known with any moderate degree of precision. Even in the commonest cases, it is perhaps altogether impossible to procure the data necessary for the

INSURANCE

accurate determination of this element. Suppose, for example, an insurance is to be effected on a ship bound on a voyage to China: in what manner is the probability of its reaching its destination in safety to be determined? Even if an accurate account had been kept of all the voyages made during a century, and the number of successful as well as the number of unsuccessful ones were precisely known, the data would still be very insufficient for determining the risk of the loss of any individual vessel. The loss of a ship is not a simple event like the turning up of a number on the face of a die. The greater or less prevalence of hurricanes at the season of the year when the voyage is to be made; the strength of the ship and sufficiency of its equipment; the skill of the commander, and the character and discipline of the crew—are all elements materially affecting the risk, but which it is impossible to reduce to numerical values and precise calculation. All, therefore, that can be done is to adopt certain mean or average values, deduced from observations of the fate of vessels in circumstances not indeed precisely the same, but having some degree of similarity. To the insurer, if he sufficiently multiplies his adventures, the result will be the same in the long run as if he had a more accurate appreciation of the separate influences of which the probability of the safe arrival of a vessel at a given port is composed; but the evil which results from this deficient knowledge of facts is, that the owner of a good ship, by paying the same premium for insurance as the owner of a bad one, is charged for indemnification against a risk which he really does not run; and hence the motives for improving the construction of vessels are not only destroyed, but it even becomes an object of pecuniary interest to expend in their equipment nothing beyond what is necessary to give them that moderate degree of goodness or seaworthiness which suffices to render them insurable on the ordinary terms. This system, however much it is to be deprecated, is rather advantageous than otherwise to the underwriters or insurers, because their premiums are charged in proportion, and it renders insurance more necessary. The pecuniary loss falls ultimately on the million who consume the merchandise; and as to the loss of human life, that consideration will probably operate as a check to cupidity only in so far as it may tend to raise the wages of seamen.

With respect to insurances against fire, the exact appreciation of the risk is not less difficult than in the case of marine insurances; but mathematical nicety on this subject is of little importance, for the amount of experience afforded by the general prevalence of the practice, and the competition which exists among the numerous rival companies, have probably had the effect of adjusting the premium to the average risk with all the accuracy which is practically attainable. The premium charged by the London offices for insuring

INTEGER

property of the value of 100*l.* for a year is one shilling and sixpence, which corresponds to an average annual loss of nearly 1 in 1,300; but it is to be observed, that the sum which is charged as premium is presumed to be sufficient not only to cover the losses, but also to defray the expenses of the establishment, and to afford an adequate interest on the amount of the capital laid out or risked by the insurance company. Stamp duties on policies of sea insurance were reduced and fixed by 7 Vict. c. 21, in 1844, on a graduated scale, varying from 3*d.* to 4*s.* for each 100*l.* insured. Those on fire insurance have been reduced during the session of 1855.

The characteristic property of insurances, of whatever nature, is their tendency to reduce to a certain average value the profits or advantages arising from all speculations of the same kind, however great the number may be. The gain which the insurer makes on his successful speculations indemnifies him for his loss by those which are unsuccessful; and to the insured the result is the same as if they had paid their premiums into a common fund, and agreed to make good to each other their individual losses. The insurers are only the intermediate agents of this supposed association, and their profits may be regarded simply as the salary of their functions. If other means exist of dividing the risks, insurance becomes unnecessary. A mercantile company employing a very great number of ships, or taking part in a very great number of enterprises, would derive no benefit from insurance. The loss on those which are unsuccessful is compensated by the premiums saved on the whole; in fact, the company acts as insurer to itself. On this principle the government does not insure vessels belonging to the royal navy nor public buildings.

Intaglio (Ital.). The term applied to gem engraving when the subject is represented as being sunk below the level of the original surface; it is the contrary to *rilievo* or *alto rilievo*.

Integer (Lat. *whole*). In Arithmetic, a whole number as opposed to a fraction or mixed number. In general, the adjective *integral* is applied to quantities and functions to denote the absence of fractional forms. A *complex integer* in the theory of numbers is of the form $a + b\sqrt{-1}$, where a and b denote ordinary (real) integers. The theory of complex numbers was founded by Gauss in 1825 (*Theoria Resid. Biquadraticorum*); but the most lucid exposition of its elementary principles was given by Dirichlet in Crelle's *Journal*, vol. xxiv. The product $a^2 + b^2$ of a complex number $a + b\sqrt{-1}$, and its conjugate $a - b\sqrt{-1}$ is called its *norm*, and denoted by either of the symbols

$$N(a + b\sqrt{-1}), N(a - b\sqrt{-1}).$$

The four associated numbers

$$\begin{aligned} & a + b\sqrt{-1}, a\sqrt{-1} - b, \\ & -a - b\sqrt{-1}, -a\sqrt{-1} + b, \end{aligned}$$

INTEGRAL CALCULUS

as well as their respective conjugates, have all the same norm. A complex number is said to be *prime* when it admits of no divisors except itself, its associates, and the four units,

$$1, -1, \sqrt{-1}, -\sqrt{-1}.$$

Many of the higher arithmetical theorems, such as that of Fermat, may be extended to complex numbers.

Integral Calculus. The inverse of the differential calculus. All problems in integral calculus resolve themselves ultimately to the determination of the function which has a given differential coefficient; in other words, to the discovery of the function $F(x)$, which when submitted to the direct operation $\frac{d}{dx}$ yields the

known result $F'(x)$. Thus

$$\left(\frac{d}{dx}\right)^{-1} F'(x)$$

is an appropriate symbol for $F(x)$. Another symbol for $F(x)$, however, is

$$\int F'(x) dx,$$

which denotes primarily the limit of the sum $\sum \{F'(x) \Delta x\}$,

when Δx is allowed to diminish, and the number of terms added to increase in proportion. [INTEGRATION.] Such a limit is called an *indefinite integral*. The equivalence of the above two definitions of an integral may be rigorously established by a method similar to that noticed under INTEGRATION. The following geometrical illustration of this equivalence will here suffice, and will at the same time furnish an example of one of the many important applications of the integral calculus. Let $F(x)$ denote the plane area OPMH enclosed between a curve HM, two rectangular axes OX, OY, and the ordinate MP, corresponding to any abscissa OP = x . Then if PQ be any constant increment Δx ,

$$F(x + \Delta x) - F(x)$$

will clearly represent the area of the slice MPQN which, in magnitude, is intermediate between the rectangles RP and NP. Hence

$$\frac{F(x + \Delta x) - F(x)}{\Delta x}$$

will represent a line intermediate in length

INTEGRANT PARTS

between MP and NQ. Allowing Δx to diminish, therefore, we have MP = limit of

$$\frac{F(x + \Delta x) - F(x)}{\Delta x} = \frac{d}{dx} \cdot F(x) = F'(x);$$

so that the function whose differential coefficient represents the given ordinate MP of a curve, itself represents the area of that curve, or more strictly the area

$$F(x) - F(a)$$

of any portion APMK enclosed between the curve, the abscissa axis, and the initial and final ordinates

$$F'(a), F'(x),$$

corresponding to the abscissae

$$OA = a \text{ and } OP = x.$$

But, extending the summation to all values of x between the same limits, the same area is clearly represented by the limit of the sum

$$\sum \{F'(x) \Delta x\}.$$

The latter is called a *definite integral*, having the limits a and x , and is denoted by

$$\int_a^x F'(x) dx;$$

its value, provided $F'(x)$ remains finite between the limits, is, as we have seen, equal to

$$F(x) - F(a),$$

where $F(x)$ is the function which, operated upon by $\frac{d}{dx}$, yields the given result $F'(x)$. With respect to the indefinite integral

$$\int F'(x) dx,$$

therefore, we have the symbol

$$\left(\frac{d}{dx}\right)^{-1} F'(x),$$

and the value $F(x) + C$, where C is a constant.

The subject of the integral calculus is far too wide to receive adequate exposition in such a work as the present; we shall, therefore, limit ourselves to brief definitions, in their proper places, of the principal technical terms employed therein, referring the student for further information to one of the many excellent treatises now within his reach. We may mention that those who are occupied with applications of the integral calculus will find the *Tables d'Intégrales Définies*, by D. Bierens de Haan, published by the Royal Academy of Sciences at Amsterdam, of great service. Another, older and less complete, but still useful, work of the same kind, is Minding's *Sammlung von Integraltafeln*, Berlin 1849.

Integral Multiple. [MULTIPLE, INTEGRAL.]

Integrals, Eulerian. [EULERIAN INTEGRALS AND GAMMA-FUNCTION.]

Integrand Parts. In the CORPUSCULAR PHILOSOPHY [which see], the small parts of a body, by the aggregation of which it may be

INTEGRATING FACTOR

conceived to be formed. *Integrant parts* result from the mechanical division of a body; *constituent parts* from its chemical decomposition.

Integrating Factor. In the integral calculus, a function of the variables which, when multiplied into every term of a differential equation, has the property of rendering the latter an *exact* differential equation. [DIFFERENTIAL EQUATION.] Every differential equation of the form $Mdx + Ndy = 0$, where M and N are given functions of x and y , has an infinite number of integrating factors. If μ be any one of them, however, all the rest are easily found; for if v be the function whose exact differential is $\mu M dx + \mu N dy$, then $\mu f(v)$, where f is an arbitrary functional symbol, will also be an integrating factor. These integrating factors are, indeed, particular integrals of a *partial* differential equation of the first order, for by their definition we must have

$$\frac{d(\mu N)}{dx} = \frac{d(\mu M)}{dy}$$

$$\text{or} \quad N \frac{d\mu}{dx} - M \frac{d\mu}{dy} = \left(\frac{dM}{dy} - \frac{dN}{dx} \right) \mu.$$

Now, this equation can only be solved in particular instances; its general solution, indeed, would require a previous knowledge of the general solution of the ordinary differential equation from which it was derived.

Similarly, if μ be an integrating factor of the ordinary differential equation

$$P dx + Q dy + R dz = 0,$$

then the three conditions

$$\frac{d(\mu Q)}{dx} = \frac{d(\mu R)}{dy}, \quad \frac{d(\mu R)}{dx} = \frac{d(\mu P)}{dz},$$

$$\frac{d(\mu P)}{dy} = \frac{d(\mu Q)}{dz}$$

must be satisfied. By developing these equations, however, it will be found that their simultaneous satisfaction is possible only when

$$P \left(\frac{dQ}{dx} - \frac{dR}{dy} \right) + Q \left(\frac{dR}{dx} - \frac{dP}{dz} \right) + R \left(\frac{dP}{dy} - \frac{dQ}{dz} \right) = 0.$$

is satisfied identically—a condition whose fulfilment indicates, conversely, that the proposed equation admits of a single primitive. Under ordinary circumstances, it may be added, the general solution of the equation under consideration consists of two simultaneous equations in x , y , and z , one of which is arbitrary in its form.

Integration. In ordinary acceptance, this term denotes the summation of any number of terms of a series whose law, or general term, is given. The operation of summation is denoted by the symbol Σ , prefixed to the general term; thus $\Sigma [\phi(t) \cdot \Delta t]$, where $\phi(t)$ is a given function, and Δt , the

INTEGRATION

constant increment of its independent variable, indicates the summation of a number of terms, obtained by giving to t successive values, having the common difference Δt . According to this, Σ would appear to be the symbol of a direct and always possible operation; in reality, however, this is not the case; for, as we shall shortly see, the real object sought, the *integral*, is a function upon which the performance of a known direct operation leads to a given result. When the increment Δt is finite, the problem of summation falls within the scope of the calculus of differences, and the process which it involves is termed *finite integration*. When the increment Δt is allowed to diminish indefinitely, whilst the number of terms to be added is increased proportionally, the question arises as to what *limit* the sum will approach. The answer to this enquiry is furnished by the **INTEGRAL CALCULUS** [which see].

With respect to finite integration, it will be sufficient to consider the case where the increment $\Delta t = 1$. In fact, if $\Delta t = h$, we have merely to put $t = hx$, when we shall have $\Delta x = 1$, and, provided u_a be an initial value of the general term u_x of a series,

$$\Sigma u_x = u_{x-1} + u_{x-2} + \dots + u_a.$$

Putting $x+1$ in place of x adds a term more to the series, so that the difference of the two sums is

$$\Delta (\Sigma u_x) = \Sigma u_{x+1} - \Sigma u_x = u_x,$$

and we see at once that Δ and Σ are *inverse symbols of operation*, in other words that Σu_x indicates the function which when operated upon by Δ yields the given result u_x . The symbol Σ , therefore, may be properly replaced by Δ^{-1} , and regarded as of an *interrogative* rather than of a *directive* character. Finite integration thus resolves itself into an *inverse method of differences*, the results of which are to be tested by the performance of the direct operation denoted by Δ . Hence if v_x denote a function whose difference is u_x , we shall have $\Sigma u_x = v_x + C$, where C is an ordinary constant, or more generally a *periodical constant*, that is to say a function of x whose value remains unchanged when x is replaced by $x+1$. The value of C in any actual summation depends obviously upon the initial term u_a , and may be found by putting $x = a+1$.

An important class of rational functions may be integrated by means of the formula

$$\Sigma (ax+b)^{(m)} = \frac{(ax+b)^{(m+1)}}{a(m+1)} + C,$$

which is true for negative as well as positive values of m , provided the definition of the factorial expression $(ax+b)^{(m)}$ be borne in mind. [FACTORIAL.] A useful formula for the integration of a rational and integral function of the n^{th} degree is also

$$\Sigma u_x = C + xu_x - \frac{x^{(2)}}{2!} \Delta u_x + \frac{x^{(3)}}{3!} \Delta^2 u_x - \&c. \dots$$

INTEGRATION BY PARTS

$$(-1)^{\frac{x(n+1)}{n}} \Delta^n u_x.$$

Another method of frequent application is that of *integration by parts*, according to the formula

$$\Sigma u_x \Delta v_x = u_x v_x - \Sigma v_{x+1} \Delta u_x,$$

which may be easily verified. Thus

$$\Sigma u_x a^x = u_x \frac{a^x}{a-1} - \Sigma \frac{a^{x+1}}{a-1} \Delta u_x,$$

so that if u_x is a rational and integral function of the n^{th} order, the integration of $u_x a^x$ may be effected by $n+1$ operations of the above kind. For works on finite integration, see DIFFERENCES, CALCULUS OF.

Integration by Parts. A method frequently employed with advantage in the integral calculus. The following formula, deducible at once from the well-known form of the differential of a product, viz.

$$d(uv) = u dv + v du,$$

will sufficiently explain the nature of the process:

$$\int u dv = uv - \int v du.$$

Integument. In Botany. [EPIDERMIS.]

Intellect. [UNDERSTANDING.]

Intendant (Lat. *intendo*, *I give my mind to anything*). A title in common use among the French, applied to persons who have the conduct, inspection, and management of any office or function; as intendants of the marine, of the finances, of provinces, buildings, houses, &c., which are all self-explanatory terms.

Intentions, First and Second. A distinction drawn by the schoolmen between those acts of thought which relate to an object out of the mind, and those which consist in the mind's reflex action on its own states of consciousness. Thus the generalisations *animal*, *production*, are *first intentions*: such terms as *abstraction*, *inference*, &c., are the expression of *second intentions*. It is to be regretted that this distinction is disused by modern enquirers, or misunderstood by them, as in particular by Whately. Great ambiguity might be avoided in philosophical language were it closely kept in view; as in such terms as *cause* and *effect*, which may either allude to a connection between natural phenomena in themselves, or to our mode of viewing them derived from the essential laws of the understanding. The distinction was first revived in the present century, in a learned and acute review of Whately's *Logic* (*Edinburgh Review*, No. 115).

Intercalary Day (Lat. *intercalo*, *I insert*). In the Calendar, a day inserted out of the usual order to preserve the account of time. Thus every fourth year containing 366 days, while the other years contain only 365, one of the months in that year must have an additional day, which is called the intercalary day. The additional day was given to February, as being the shortest month, and in the ancient Roman calendar was inserted between the 24th

INTERDICT

and 25th days. In the ecclesiastical calendar it still retains that place; but in the civil calendar it is the 29th. [LISSEXTILE; CALENDAR.]

Intercellular Passages. In Vegetable Anatomy, the spaces between the cells, tubes, or vessels of which the tissue of a plant consists. As the cells are usually, and the tubes or vessels always round, it necessarily follows that when pressed together there will be spaces left between their sides.

Intercept (Lat. *interceptus*, part. of *intercipio*). In Geometry, this term denotes the portion of any line intercepted between the intersections of the latter by other two lines, by a curve, by two planes, or by a surface. The intercepts made on the coordinate axes by any plane or line are the distances, with their proper signs, from the origin to the intersections of the axes by such a plane or line. The equation of a plane, expressed by means of such intercepts a , b , c , takes the very convenient form

$$\frac{x}{a} + \frac{y}{b} + \frac{z}{c} = 1.$$

Intercolumniation (Lat. *inter*, *between*, and *columna*, *a column*). In Architecture, the space between two columns, measured at the lowest part of their shafts. It is one of the most important elements in a building, and on it depend the effect of the columns themselves, their proportion, and the harmony of an edifice. Intercolumniations are of five species, viz. **ARCEOSTYLE**; **DIASTYLE**; **EUSTYLE**; **PTYCHOSTYLE**; and **SYSTYLE** [which see].

Intercostal (Lat. *inter*, and *costa*, *a rib*). In Anatomy, a designation of certain blood-vessels, nerves, and muscles, situated between the ribs.

Interdict (Lat. *interdictum*, from *interdico*, *I forbid*). In Ecclesiastical History, a spiritual weapon by which the popes used in former times to reduce individuals or whole states to the most abject submission. In the middle ages it was the most terrible blow which could be inflicted on the people or the prince. When an interdict was laid upon a kingdom, all spiritual services ceased; the churches were shut up; the sacraments were no longer administered; no corpses were buried with funeral rites; and all the ministry of the church, which was then believed to be the only channel of salvation, was forbidden to be exercised. The first memorable occasion on which this method of warfare was adopted was the marriage of King Robert of France with Bertha his cousin, when Gregory V. in 998 issued interdicts against the whole country, and compelled the sovereign to dissolve his union. It had, however, been often used before by bishops; an instance is quoted by Moreri as early as A.D. 870. (Gieseler's *Text-book* ii. 117, transl.) The ban under which England was laid in the reign of John by Innocent III. is well known in the history of this country. The latest pretensions to the exercise of this power were assumed by Pius VII. when he issued an inefficient decree against Napoleon in 1809.

INTERDICT

INTERDICT. The technical term in Roman law for a decree of the prætor concerning the acquisition, retention, or recovery of property.

Interest. The premium or sum of money given for the loan or use of another sum of money, generally estimated at so much per cent., or per 100*l.* The sum lent, and for which the interest is paid, is called the *principal*, and the sum charged as interest is called the *rate*. The rate will evidently be proportional to the time; for whatever interest is paid for the use of 100*l.* for one year, twice that interest will be required for the use of 100*l.* for two years. The principal added to the interest, or the whole sum paid back to the lender, is called the *amount*.

Interest is either *simple* or *compound*. *Simple interest* is that which is reckoned and allowed upon the principal only during the whole time of the loan: *compound interest* is reckoned not only on the principal sum lent, but also on the interest as it becomes due.

All questions in simple interest may be solved by means of the easily demonstrated formula $a = p(1 + rn)$, wherein a denotes the amount, p the principal, n the number of years, and r the rate of interest to be paid yearly for every pound lent. By this formula any one of the four quantities a , p , r , n can be at once calculated, when the remaining three are given.

Similarly, questions relating to compound interest may be solved by the formula $a = p(1 + r)^n$, where the letters have the same signification as before. It will be observed that here certain questions can only be solved approximately. For instance, if it were required to find the number of years in which a sum of money would double itself, at 5 per cent. compound interest, we should have $a = 2p$, $r = .05$, hence $(1.05)^n = 2$; an exponential equation which solved, approximately, by logarithms gives

$$n = \frac{\log 2}{\log 1.05} = \frac{.3010300}{.0211893} = 14\frac{1}{2} \text{ nearly.}$$

If the interest be payable m times a year, the value of money or *nominal* rate of interest being the same, the preceding formula would have to be replaced by

$$a = p(1 + \frac{r}{m})^m.$$

Now when m increases indefinitely, the coefficient of p here is well known to approach the limit e^{rn} , where e is the base of the Napierian system of logarithms, i.e. approximately, 2.718281828. Hence we conclude that if interest were due *every* instant, the principal p would amount in n years to $a = pe^{rn}$. For instance, if money were worth 5 per cent. and interest were due every instant, 100*l.* would, in a year's time, amount to $100\text{.} \times e^{.05} = 105\text{.} 2\text{ s. } 6\frac{1}{2}\text{ d.}$ nearly.

INTEREST. In Political Economy, the compensation made to lenders by borrowers, in consideration of the use and employment of their capital, has been defined by the late Mr. Senior as the wages of abstinence. It is clear that if an individual lends another a portion of his

INTEREST

capital, he may not only expect to recover his loan, but is justified in demanding a certain recompense for surrendering to the profit of another that which he might have applied to his own advantage. Since, however, there is apparently no spontaneous increase in the advance made, many persons, not only in ancient times, but even to the present day, have censured the taking of interest as a wrong practised on society for the profit of those who possess money. So absurd a notion hardly deserves a serious answer; but it will be clear that a similar objection may be taken to the existence of rent, or even to profit of any kind. The advance, whatever it may be, is only under the form of money, and is practically a permission to use that claim upon his portion of collected wealth which the possessor of capital may make. If the capitalist sells his right to the portion to which he is entitled, and receives immediate payment for his property, it becomes the every-day transaction of a bargain. If, however, he postpones the acceptance of his price for the value which he transfers, i.e. makes a loan of the value which belongs to him, he is entitled also to the natural increase, that is to the market rate of profit on that which he advances, in other words he has a claim to interest. This rate is determined strictly by the principle of competition; the desire of the capitalist to employ his accumulations for profit, and the desire of borrowers to procure material on which to exercise their skill, diligence, and intelligence, being constantly present in civilised communities. When the capital to be invested is larger than the demand of borrowers, the rate of interest is low; when the demand of borrowers is greater than the amount of capital to be had, the rate is high.

From certain permanent fallacies which have in the infancy of economical science occupied even the ablest minds, and which are not extinct even at present, governments have constantly attempted to regulate rates of interest. This interference with the natural freedom of commercial action has occasionally been justified by a reference to the Mosaic prohibition of usury; but sometimes it is argued that lenders are unproductive consumers of part of the profit which is procured by labour. Such a notion, however, leaves out of sight the fact that production is impossible without capital, and that all capital is accumulated and employed with a view to profit. Again, it is alleged that if the trade in advances be not regulated by the authority of the legislature, borrowers are open to all the fraud and extortion of unprincipled lenders. But if by any injudicious enactments, or indeed by any enactments at all, the business of the lender is interfered with, it will not follow that borrowing will cease or even be diminished; but it will follow that the trade in loans will fall into less scrupulous hands; and it is certain in any case that the borrower will have to pay whatever additional charge may be imposed by the lender, in the event of

INTEREST

his reputation being diminished, his profits threatened, or his capital imperilled. All legislative enactments, therefore, the purpose of which has been to check or control the rates at which advances are made, have been accompanied by increased hardships on borrowers. It is of course the duty of governments to protect all persons against fraud and wrong, and even to annul the contracts of incapable persons. It may, perhaps (though it might be more difficult to vindicate such a position), be obligatory on governments to protect persons against their own folly; but it is utterly absurd for the legislature to affect the general regulation of contracts, and the prices at which services are appraised. It is as preposterous to attempt the direction of the price of money, as it is found to be to regulate the price of food; it is even more unwise, for evasions of such regulations are very easy and obvious to the lender, though, as has been said, exceedingly onerous, expensive, and mischievous to the borrower.

For rates of interest in Greece and Rome, the reader may be referred to Boeckh's *Public Economy of Athens*, and Niebuhr's *History of Rome*. We know from the New Testament that interest was paid on bankers' deposits in Judaea. In Europe it was alternately prohibited and permitted, the clergy being generally hostile to the practice. In the Italian republics, however, the trade in money was recognised and common. In 1546, it first received a parliamentary sanction in England, and was fixed at 10 per cent., but in 1562 was again prohibited. Mary, however, borrowed at 12 per cent., which appears to have been the usual rate at that period in Antwerp. In 1571, it was again made legal at 10 per cent., a rate at which the Scotch parliament fixed it in 1587. The rate fell at the beginning of the seventeenth century, James I. having borrowed in Denmark at 6. In 1624, it was reduced to 8; in 1651, to 6; in 1724, to 5, at which legal rate it remained till all usury laws were repealed, an event which occurred only a few years ago. In 1778, it was limited to 12 in India.

In 1660, according to Sir Josiah Child, the rate in Scotland and Ireland was from 10 to 12; in France 7; in Italy and Holland 3; in Spain from 10 to 12; in Turkey 30; but the East India Company, while the legal English rate was 6, contrived to borrow at 4.

Much of the misconception prevalent as to the nature of interest is due to the confused way in which the words *labour* and *profit* are used. Labour is generally limited to muscular exertion only, and profits are therefore often held to contain part of the wages or remuneration of labour. This confusion is particularly common in such cases as those in which the three objects in economical distribution, wages, profit, and rent, are united in the same person.

When advances are made at interest, and the true rate of interest is calculated from these advances, the corpus or principal must supposed to be absolutely safe, and to be

certainly replaced at the end of the period at which the advance is due to the lender. If it were possible that by the course of events in any particular case, the capital repaid would be more valuable at the period at which its replacement is due, than it is when the advance is made, the rate would fall below the market rate; if it were less in amount, it would be more. Thus, suppose an advance be made for joint-stock purposes, and it be seen in a short time that the property of the lender is more valuable than when it was first lent or advanced, the rate would rise, or, what is more familiar, the market value of the capital would be above par. If on the other hand the property is depreciated, the rate will fall, and the share be at a discount. It is true that advances of money to be paid in money will not, if the corpus be secured, fall in value, except to some extent and under certain circumstances, in bills of exchange; but in case any risk of the principal arises, the lender will require larger compensation proportionate to the risk, such larger compensation representing really a replacement of capital; and whenever monetary transactions are effected on a large scale, it can hardly fail but that some portion of this compensation for risk will fall on persons whose credit is quite unimpeachable. When, therefore, high interest is said to be synonymous with bad security, the expression means, that there is added to the interest another payment which virtually tends to replace capital, and that the whole mass of transactions must imply and contain an insurance to lenders. So, again, when advances are made for undertakings which terminate within a specified time, as leases of mines, where the apparent high rate of profit must be divided into two portions, one of which is the interest on the advance, the rate of which is regulated by the same competition as governs the rates of interest generally; the other, which is relative to the necessity of replacing that capital which is by the very terms of the lease extinguished at the conclusion of the time. It is important to recognise this distinction, because we shall find that by a negligent use of the word *profit* one of the elements in the rate of payment made on advances, and which is really the capital of the lender returned to him, or insured to him, by the natural operations of trade, is made the subject of taxation.

Similar to the condition, that, in order to determine the real rate of interest, the advance must be considered to be absolutely secured to the lender, is another, that the lender should exercise no care, supervision, or labour in the employment of the capital. But the word *profit* is frequently employed to denote the returns of the business, in which the greater part of the rate received and appropriated by the lender is to all intents and purposes the wages of labour. Now, it is essential for many purposes that several causes determining the equation of profits should be separated and

For instance, suppose the rate of so-called

INTERFERENCE

profit in any trade is 10 per cent.; that is to say, let us imagine that a trader has employed 10,000*l.* in business, and expects, and on the whole gets, 1,000*l.* annually clear upon the capital he has invested. The rate of interest on his capital is plainly determinable by several factors. We may take the rate of discount, and deriving an average from the duration of high and low rates, and if possible from the number of transactions negotiated at the several rates, supply one quantity from these considerations. Next, we may take the price of consols. Next, with some limitations, especially those which respect its political influence, and its prospective value, the rent of land. Finally, we may take mortgage rates, though as these are not readily transferable, some deduction must be made from their value, in consequence of the partial but mischievous effects of the stamp duties and other legal charges upon these transactions. The product may be easily arrived at, and say for the sake of illustration that the amount is 4 per cent. Next we take the element of risk, an element which is lessened in proportion to the breadth of the area on which transactions are negotiated, and to the number of the transactions themselves. And lastly we must reckon the wages of labour, wages not the less paid because the exertion is mental, and not the less real because they are not separated from the gross remuneration.

Interest should be distinguished from discount. The fluctuations of the rate in the latter are far more frequent and considerable than in the former. When advances are plentiful, the rate of discount is ordinarily lower than the rate of interest, because the advance is for a short period, and the capital lent is rapidly recovered. But when money is scarce, the rate is higher than that of interest, because every person who borrows pledges himself to meet his obligation in cash or its equivalent at a given time, and the supply falling short of the demand, or, what is the same thing, readiness to give credit being contracted, more persons are actively competing for a limited but necessary value. [DISCOUNT; PROFIT; USURY.]

Interference (Lat. *inter*, and *fero*, *I bring*). In Optics, a term first employed by Dr. Young to express certain phenomena which result from the mutual action of the rays of light on each other. The phenomena in question are considered of very great importance, and have accordingly been examined with great care, on account of the proof which they give of the truth of the undulatory theory of light.

It is well known that if two series of waves be produced upon a smooth surface of water, in such a manner that the two series will pass through each other: then, where the crests of two waves (one from each series) coincide, a wave of increased height will result; whilst in those places where the crest of a wave of one series coincides with the hollow of a wave from the other series, smooth water will result. Now, just as ripples are produced upon water by mechanical impact, so are waves or undulations

created by a luminous body in the ether with which the universe is supposed to be pervaded: and it is these waves which, penetrating to the retina of the eye, produce the phenomena of vision.

If two series of these ethereal undulations intersect each other in such a manner that the crests of the waves of one series fall into the hollows of the waves of the other, the phenomenon termed *interference* is produced, and the two rays of light whose undulations thus neutralise each other are perfectly extinguished as regards luminous effect. This production of perfect darkness from two rays of light can, however, only occur when the light is monochromatic, since the ethereal waves producing the different colours of light possess different lengths, and consequently, if the waves of the two series are in such a relative position as to extinguish one of the colours of white light, then the remaining colours will not be affected; but as white light is composed of a number of pairs of colours which are complementary to each other, the mixture of each pair producing white light, it follows that no single colour can be thus extinguished without imparting to the residuary light the opposite or complementary colour. Thus the phenomenon of interference is attended, in the case of ordinary white light, with the most beautiful displays of colour, and some of the most magnificent colour effects in nature are thus produced. The colours of thin films of soap bubbles, or of oil upon water, the gorgeous tints of the humming bird, of the wing-cases of beetles, and of many shells, owe their origin to this cause. This interference between two rays of light can be produced in several ways; but as an illustration, it will suffice to describe the phenomenon as seen in the soap bubble.

Suppose a ray of light to fall upon the external surface of a soap bubble: the ray is divided into two parts, one of which is reflected or thrown back from the surface, whilst the other passes into the substance of the film and arrives at the inner surface of the latter, where it is again divided into a ray which emerges into the interior of the bubble, and another ray which is reflected back again towards the outer surface. A portion of the latter ray emerges from this outer surface, and mingles with the ray which is reflected on the first impact of the light upon the exterior surface of the bubble. Now, it is obvious that the two rays of light which are thus made to pursue the same path have not travelled the same distance; for whilst one has been reflected from the outer surface of the film, the other has twice crossed the substance of the film. The undulations of the latter are thus thrown behind those of the former, and to such an extent as to cause the crests of the waves of some one colour of the white light of one ray to fall into the hollows of the waves of the same coloured light in the other ray. Thus that particular colour is extinguished, whilst the residual light becomes tinted of the complementary colour. If inter-

INTERIM

ference has occurred with the blue rays, the residual light will be yellow. If the waves of yellow light have neutralised each other, a blue ray will result. The extinction of green produces crimson: that of crimson, green light; and so on. Now as the soap-bubble film varies in thickness, both in different parts at the same time, and in the same portion at different times, it follows that at almost any given moment each of these colours will be visible on different portions of the bubble, and that one and the same part of the bubble will continually change its hue as its thickness varies.

Interim (Lat. *in the mean time*). In modern European History, the name given to a decree of the emperor Charles V. (after the overthrow of the Protestant League of Smalcald) in which he attempted to reduce to harmony the conflicting opinions of the Protestants and Romanists. The use of the cup, however, and the marriage of the clergy, were the only points which he conceded to the Reformers; and it became a question among them, and gave rise to many serious disputes, whether they could conscientiously submit even to a temporary decree of such a nature. The enactments of the *interim* were intended only to remain in force till some definitive settlement could be made; whence it derives the name by which it is generally known. It received the force of law at the diet of Augsburg, in 1548. Its provisions against the Protestants were, however, in most respects set aside by the treaty of Passau, 1552.

Interior Side. In Fortification, the line of the curtain produced from the centre of one bastion to that of the next.

Interior Slope. In Fortification, that part of the parapet sloping from the crest to the banquette; or that part of the rampart sloping from the terreplein to the natural level.

Interjection (Lat. *interjectio*, from *jacio*, *I cast*). In Grammar, a part of speech expressing simple emotion, without involving any act of conception. [GRAMMAR.]

Interlocutor (Lat. *inter*, and *loquor*, *I speak*). In Literary phraseology, a person who is introduced as taking part in a dialogue; in Dramatic Literature, termed *dramatis persona*: the latter name, however, comprehends such as appear on the stage, but take no part in speaking, termed by the Greeks *κωφοί πρόσωπα*, *mute personages*.

Interlocutory Judgments. In Law, such as are given in the course of a cause upon any proceeding arising out of it, and do not finally determine it: as, the judgment in an action of damages upon which a writ of enquiry issues to assess such damages. So a decree in chancery is either final or interlocutory. In Scottish law, a judgment of the court of session, or lord in ordinary, which, if allowed to become final, will be conclusive, is termed *interlocutor*.

Interlude (Lat. *inter*, and *ludo*, *I play*). A short dramatic piece, generally accompanied with music; properly, such as is represented

INTERMITTING SPRINGS

or performed between the acts of longer performances.

Intermede or Intermezzo (Ital.). In Dramatic Literature, nearly the same with *interlude*. A short musical piece, generally of a burlesque character; but many pieces not intended merely for introduction between the acts of a more serious performance are comprised under these names by the French and Italians.

Intermediate Shaft. In Marine Engineering, the term *intermediate shaft* is applied to the strong shaft that runs across the frame of the engines, to connect the two engines and the two paddle-wheels.

Intermittent (Lat. *intermitto*, *I leave off*). Any disease which ceases for a time and again returns, so that the patient is free from it in the intermediate intervals. [ACQUA.]

Intermitting Springs. Springs which, after having run for a certain time, stop altogether, and after a time begin to run again, and then stop, and so on alternately; the flowings and intermissions generally succeeding each other at pretty regular intervals. These phenomena, which have sometimes been ascribed to the influence of witchcraft, are explained on the principle of the siphon. Let *A* be a cavern in a mountain, and

abc a channel communicating with *A*, and terminating on the side of the mountain or adjacent plain; and let us suppose the cavern to be fed by small streamlets of water, of which the united supply is less than can be discharged by the channel *abc*. Let the cavern be supposed empty. The water from the rills or fissures by which it is fed will collect at the bottom, and as it rises in the cavern will also rise in the channel *ab* till it reaches the highest level *b*, when it will begin to flow out through *bc*, and by the property of the siphon will continue to flow till the whole cavern is drained to the level of *a*. The cavern then begins to fill anew, and the same series of phenomena is repeated at intervals, of which the length depends on the relative capacity of the cavern and channel, and the abundance of the supply through the fissures. When the supply is constant, the intervals of intermission will be equal. Some springs of this kind do not cease altogether to flow, but only discharge a much smaller quantity for a certain time, and then a greater quantity. In this case they are called *variable* or *reciprocating* springs. They may be caused by the circumstance of a smaller fissure connecting the cavern with the lower part of the channel *c*, through which a portion of water continues to flow while the main discharge is stopped; or there may be several siphons all communicating with a common outlet. It is easy to imagine a combination of circumstances by which the discharge of water will be greatly increased by the elastic force of air compressed at the top of the cavern *A*. This will take place when the fissures which communicate with the external atmosphere are filled with

INTERMODILLION

water, and there is in consequence no opening by which the air in the cavern can escape. An interesting example of one of these springs may be seen at the village of Giggleswick, near Skipton, in Yorkshire. A powerful rush of water issues from this spring at intervals, varying from five minutes to one hour, according to the wetness or dryness of the season.

Intermodillion. In Architecture, the space between two modillions, which is the same throughout the entablature.

International. That which relates to transactions between independent nations, acknowledging no common superior. In this sense we speak of *international law* as an important branch of the so-called *LAW OF NATIONS* [which see], and *international copyright* [COPYRIGHT]. It may be expedient to lay down a caution against an incorrect use of the word which has of late arisen, namely, in the sense of 'common to' all or several nations: e.g. an *International Exhibition of Industry*.

Internode (Lat. *inter*, and *nodus*, a knot). In Botany, the space that intervenes upon a branch between the leaves.

Inter-nuncios or Embanuncios (Lat.). An envoy of the Pope, sent to small states and republics; distinguished from the *uncio*, who represents the Pope at the courts of emperors and kings. Also a species of diplomatic officers, who ranked, according to the old practice, between ambassadors and plenipotentiaries. Since the congress of Vienna, in the rules of which no mention is made of inter-nuncios, they are considered on a level with plenipotentiaries. This is (or lately was) the title of the Austrian envoy at Constantinople.

Interosseous Muscles. Small muscles between the metacarpal bones of the hand and the metatarsal of the foot: the former are concerned in moving the fingers, and the latter the toes.

Interparietal (Lat. *inter*, and *paries*, a wall). In the early Aymará or Peruvian races, the skulls of which have been found at the borders of Lake Titicaca, a supposed peculiar configuration was observed by Dr. Bellamy and Professor Tschudi, viz. the separation during life of the upper half of the superoccipital, a presumed embryonic character persistent in some lower animals. This anomaly has been observed in individuals of most races.

Interpilasters. In Architecture, the space between two pilasters, which depends upon the same rules as the intercolumniation, more especially if both be employed in the same building.

Interpleader. In Law. A bill of interpleader, in equity, is filed by a person who is under an obligation or the like to one of two parties, but cannot ascertain to which of the parties he is indebted, and by his bill he calls upon the parties to interplead, and settle their claims between themselves, in order that he may bear himself harmless in the event of the success of either party. In the common law courts, by 1 & 2 Wm. IV. c. 58, relief can

INTERPOLATION

be given in some cases against adverse claims made on sheriffs and other officers, and persons having no interest in the subject of such claims, by a judge's order calling on the third party to appear and maintain or relinquish his claim.

Interpolation (Lat. *interpolatio*). Mathematically considered, the general problem of interpolation may be thus stated: Given a number of particular values of a function, to find its general value. If the *form* of the function were known, and the data sufficiently numerous, the problem would, of course, be a perfectly determinate one, and capable of easy solution. Usually, however, this is not the case.

In Astronomy and Physics, for instance, interpolation usually signifies the method of finding a mathematical law which will connect together a number of observed facts. Thus, supposing twenty places of a comet have been determined by observation; these places are said to be interpolated when a curve defined by an analytical equation has been found which passes through them all, for by means of this curve the place of the comet at any intermediate time can be found. According to this view of the subject, the problem of interpolation is altogether indeterminate; for an infinity of curves of different forms may be found which will pass through twenty given points; but in general the circumstances of the question impose such restrictions as render it determinate. In the instance now given we know that the curve must be an ellipse; and as an ellipse cannot be made to pass through twenty points taken anyhow, the question resolves itself into this: To find the ellipse which will *most nearly* pass through the given points, or represent the given observations. Another question now arises, What condition must be fulfilled in order that the observations may be represented *most nearly*? This condition must be determined from other considerations. Suppose the condition to be that the sum of the squares of the errors of observation (that is, of the differences between the observed places of the comet and the corresponding places in the orbit to be found) shall be a minimum; the problem is now quite determinate, though its solution may be sufficiently difficult and laborious.

Most frequently the form of the function, some of whose particular values are given, is assumed to be algebraic, rational, and integral; and the problem of interpolation, geometrically expressed, resolves itself to finding the parabola

$$y = A_0 + A_1x + A_2x^2 + \dots + A_{n-1}x^{n-1}$$

of the highest possible order, which shall pass through a given number of points. If a particular values are known, the order of this parabola will obviously be $n-1$, since in its equation, as above written, there are n constants to be determined. When the given values of y are *equidistant*, in other words correspond to

INTERPOLATION

equidifferent values of x , the calculus of differences furnishes at once the required formula for interpolation. Taking the first ordinate as ordinate axes, and the common difference of the successive abscissæ as unit, we have

$$y = y_0 + x \Delta y_0 + \frac{x(x-1)}{1.2} \Delta^2 y_0 \&c. \dots \\ + \frac{x(x-1) \dots (x-n+2)}{1.2 \dots (n-1)} \Delta^n y_0,$$

where y_0 represents the first ordinate, corresponding to $x=0$, and Δy_0 , $\Delta^2 y_0$ &c. . . the successive differences of the given series

$$y_0, y_1, y_2, \dots y_n.$$

The n^{th} difference $\Delta^n y_0$ vanishes, of course, in consequence of the assumed form of the function y .

When the given values of y are not equidistant, but correspond to the values $a_1, a_2, \dots a_n$, of x , then it is best to assume, instead of the above, the equivalent form

$$y = A_1 (x-a_2)(x-a_3) \dots (x-a_n) \\ + A_2 (x-a_1)(x-a_3) \dots (x-a_n) + \dots \\ + A_n (x-a_1)(x-a_2) \dots (x-a_{n-1}),$$

which is readily seen to be of the $(n-1)^{\text{th}}$ degree. Putting $x=a_m$, and calling y_m the given corresponding value of y , we have obviously the general formula

$$A_m = \frac{y}{(a_m-a_1) \dots (a_m-a_n)},$$

since all terms except the m^{th} , which does not contain $(x-a_m)$, vanish.

The value of y , therefore, may be conveniently expressed in the form

$$y = \sum_{m=1}^n \frac{(x-a_1) \dots (x-a_n)}{(a_m-a_1) \dots (a_m-a_n)} y_m.$$

The method of interpolation by differences was first employed by Briggs in the calculation of logarithms; but was afterwards treated in a more general way by Wallis, Newton, Cotes, Stirling, and others. In the fifth lemma of the third book of the *Principia*, Newton has given a solution of the problem of determining the curve which passes through the extremities of any number of ordinates. By modern writers the subject is usually treated as a branch of the calculus of finite differences. It is discussed at length by Laplace in vol. ii. of the *Mécanique Céleste*, and also in the *Théorie Analytique des Probabilités*; by Lagrange, in the *Journal de l'École Polytechnique*, &c. See also the 'Treatise on Differences and Series' by Sir John Herschel in the Appendix to the English translation of Lacroix's *Differential and Integral Calculus*, or vol. iii. of Lacroix's large *Traité*, or lastly Boole's useful little *Treatise on the Calculus of Finite Differences*. Amongst the most recent researches on Interpolation, we may mention those of Tehebichef, *Petersbourg Acad. Bull.* 16, 1869; Hermite, *Comptes Rendus* t. xlviii. 1860, and Borchardt, *Abhand. der K. Akad. der Wissen. zu Berlin*, 1860.

INTERSECTION

Interregnum (Lat.). The period between the death of one king and the accession of another under the Roman monarchy, which is represented as elective; or under the republic, the space of time when there were by some accident no curule magistrates who could hold the public assemblies of the people (comitia), and during which, therefore, an interrex was appointed. There can be legally no *interregnum* in an hereditary monarchy like that of England; hence the reign of Charles II. was always computed in legal language as commencing at the execution of Charles I.

Interrex (Lat.). A person appointed to discharge the royal functions during a vacancy of the throne. According to their legendary history, the Romans first elected an interrex after the death of Romulus, and continued the custom while the monarchy lasted. The manner of their election was said to be this: the senate chose ten individuals out of its body, each of whom discharged the function of royalty for five days in an order appointed by lot. It has been supposed that these ten senators were not elected, but were the respective seniors of the ten decuries into which the original body of patricians was divided, and that this office devolved on them by virtue of their rank; but the utter uncertainty of this and other subjects in Roman tradition has been pointed out by Sir G. C. Lewis, *Credibility of Early Roman History*. An interrex was also appointed sometimes under the republic to preside over elections of magistrates, &c. when the consuls were absent, or their election declared void and no dictator had been created.

Interrogatories (Lat. *interrogo*, *I question*). In Law, written questions, proposed to witnesses who are to be examined out of court, under authority of courts where such examination is not directed to be taken *viva voce*. In equity pleading, interrogatories may be served by the plaintiff upon the defendant to be dealt with by him in his answer, and vice versa. Under the Common Law Procedure Act, 1854, parties to actions and common law had for the first time the power of procuring, by means of interrogatories, statements relevant to the questions at issue.

Interscendent (Lat. *inter*, and *scando*, *I climb*). In Algebra, a term applied by Leibnitz to quantities when the exponents of their powers are irrational. Such expressions are called *interscendent*, as holding a mean as it were between algebraic and transcendental quantities.

Intersection (Lat. *intersectio*, from *seco*, *I cut*). In Geometry, the meeting or concurrence of lines and surfaces. The number of intersections of a plane curve with a right line determines the *order* of that curve, and hence it follows that, in general, the number of intersections of two plane curves is equal to the product of their orders. The order of a surface is the number of real and imaginary intersections which it makes with a right line, and hence agrees with the order of each of its plane sections. As a consequence, the number of

INTERTIE

points in which three surfaces intersect will be equal to the product of their several orders. The order of a non-plane curve is determined by the number of its intersections with any plane, whence it follows that the order of the curve in which two surfaces intersect will be equal to the product of the orders of the intersecting surfaces, and further that the product of the orders of a surface and a non-plane curve will give the number of their intersections. It is on these principles that algebraic curves and surfaces are classified.

Intertie. In Architecture, a horizontal piece of timber framed between two points, in order to tie them together; sometimes this is called a *cross-brace*.

Interval (Lat. *intervallum*). In Military language, the space between two portions of a body of troops in line, as distinguished from *distance*, the space between troops in column.

INTERVAL. In Music, the imaginary distance between two sounds as respects their acuteness and gravity; thus, for instance, the imaginary distance from C upwards to D is called the interval of a tone; from C to E the interval of a major third; from C to G the interval of a fifth, and so on.

Intervention (Lat. *interventio*, *a coming between*). In Politics, the interposition of one state in the domestic affairs of another. The right of armed intervention is one of the most contested portions of the public law of nations; as, although practised frequently enough by the more powerful with reference to the weak, it had never been regarded otherwise than as a permitted abuse of power until the time of the congresses of Vienna, Laybach, &c., when it was publicly recognised by the leading cabinets of Europe. The principle on which this supposed right was rested was indeed that of self-defence, in suppressing principles and practices by the prevalence of which the internal peace of the intervening state was threatened. Such was the ground on which France asserted her right to intervene by arms in the political affairs of Spain in 1821, which led to much discussion, and to the strong reprobation of the alleged right on the part of British statesmen. The history of Italy from 1821 to 1849 afforded little else than a series of such *interventions*, chiefly on the part of Austria, to prevent the spread of liberal politics in portions of the peninsula not under her government. The *intervention* of the allied powers between Greece and Turkey in 1827 was based on motives of humanity. But the most remarkable instance of recent time was that of Russia, between the government of Austria and Hungary, in 1849; for which little or no reason could be assigned except the possible danger of an insurrection in Poland following the achievement of Hungarian independence. Generally speaking, it may be said that *interventions* on the ground of apprehended necessity will never cease; but that all endeavours to erect them into a branch of international law or usage are futile.

INTESTINALIA

Intestacy (Lat. *intestatus*, *that has made no will*). In Law, the condition of a party who dies without having made a will. Freehold lands and tenements in which he has an estate of inheritance descend to his heir, subject to such charges as affect real estate; copyhold lands of inheritance to the heir, by the custom of the manor; chattels must be distributed (subject to debts) by the party who takes out letters of administration to the estate and effects of the deceased, according to the provisions of the Statute of Distributions.

Intestinalia, Intestinal Worms (Lat. *intestinus, internal*). The name by which Linnæus and Cuvier have designated the class of animals which infest the interior of other animal bodies, and which indicates their most common locality, viz. the intestinal tube.

The knowledge of the intestinal worms, as a distinct class of invertebrate animals, is of a very late date. In the twelfth edition of the *Systema Nature*, 1787-8, only eleven species of true Entozoa are enumerated, and of these only six are placed among the *Intestina*—*Gordius medinensis*, *Ascaris vermicularis*, *Ascaris lumbricoides*, *Fasciola hepatica*, *Fas. intestinalis*, and *Fas. barbata*; the remaining species, viz. *Hydra hydratula*, *Tenia Solium*, *Ten. vulgaris*, *Ten. lata*, and *Ten. canina*, are ranged with the Zoophyta. Bloch's *Treatise on the Generation of Intestinal Worms*, and the succeeding work of Göze, entitled *Versuch einer Naturgeschichte der Eingeweidewürmer Thierischer Körper*, 1782, added largely to the number of the described species, and led to the foundation of some accurately defined groups, and to better ideas of classification. The first clear definition of the intestinal worms as a class, and their distribution into a system of orders and genera, are contained in the great work by Rudolphi, entitled *Entozoorum seu Vermium Intestinalium Historia Naturalis*, 8vo. 1808-10. In this work, Rudolphi, after dividing the great class *Vermes* of Linnæus into four classes, viz. *Mollusca*, *Gymnodela*, *Entozoa*, and *Phytozoa*, characterises the third class as follows: 'Entozoa ergo classem, aut si mavis ordinem, sistunt peculiarem continentem, aliis in animalibus obviu, oculis nudis conspicua, nervis carentia, partibus internis dissimilibus instructa.' Of the class of animals thus characterised, Rudolphi enumerates, in a subsequent work, *Synopsis Entozoorum*, 1819, upwards of 1,100 species. At the present time, nearly double that number of Entozoa are known.

Rudolphi distributes the intestinal worms into five orders, which are characterised as follows:—

Order I. *Nematoidea* (Round-worms).—Char.: Body elongated, rounded, elastic; an intestinal canal, with a separate mouth and vent; sexes distinct.

Order II. *Acanthocephala* (Hooked-worms).—Char.: Body roundish, utricular, elastic; head with a retractile proboscis, armed with hooks or recurved spines; sexes distinct.

INTESTINALIA

Order III. *Trematoda* (Fluke-worms).—Char.: Body soft, rounded, or flattened; suctional pores; male and female organs in the same individual.

Order IV. *Cestoida* (Tape-worms).—Char.: Body elongated, flattened, soft, continuous, or articulated; head either simply labiated, or provided with pits (*bothria*), or suctional; orifices, either two or four in number; male and female organs in the same individual.

Order V. *Cystica* (Hydatids).—Char.: Body flattened or rounded, continued posteriorly into a cyst, which is sometimes common to many individuals; head provided with two or four pits, or with four suckers, and with a circle of hooklets, or with four unarmed or uncinated tentacles; sexual organs hitherto indiscernible.

The Entozoa which are included in the last four orders of Rudolphi have no distinct intestinal canal; and Cuvier considered the presence of this structure in the *Nematoidea* of Rudolphi of sufficient importance to form the character of a primary group, equivalent to all the remaining orders combined; and he observes that the orders thus distinguished might form two classes.

The first order Cuvier terms *Cavitaires*; and he includes in it not only the Nematoïd Entozoa, but also the genus *Pentastoma* of Rudolphi, and the Epizoa, or *Vers rigides* of Lamarck.

The organisation of the *Pentastomata*, which were defined, prior to Rudolphi, by Froelich, under the name of *Linguatula*, entitles them to rank with the highest organised Entozoa (*Zoological Trans.* vol. i. p. 381, pl. 41); but, with respect to the Epizoa, or the external Lernean parasites of fishes, although they agree with the *Nematoidea* and all other Entozoa in the absence of distinct respiratory organs, yet the ciliated natatory extremities which they possess in the young state, and the external ovarian appendages of the adult, are characters which raise them above the Entozoa, and indicate their intimate relations with the Siphonostomous Crustaceans.

Professor Owen has, therefore, combined the *Nematoidea* of Rudolphi with the genera *Linguatula*, *Poroccephalus*, and *Syngamus*, &c., which, under the habit of Cestoid or Trematode worms, mask a higher grade of organisation, to form a class under the name of *Cœlelmntha*. This class already embraces the types of three different orders, of which one is formed by the *Nematoidea* of Rudolphi; and a second has been established by Diesing, for the *Linguatula*, and other congeneric species, under the name of *Acanthotheca*. The remarkable organisation of the genus *Syngamus*, as described by Siebold, clearly indicates the type of a third order of *Cœlelmntha* [see that word].

The four orders of intestinal worms which have no distinct intestine, but in which the digestive function is carried on in blind canals, excavated in the parenchymatous substance of the body, Cuvier combines into a group, which

he terms *Vers intestinaux parenchymateux*, and for which Prof. Owen has proposed the name of *STERELMINTHA* [see that word].

This group Cuvier subdivides into three families, or orders; the first corresponding to the *Acanthocephala* of Rudolphi, the second to the *Trematoda*, and the third being equivalent to the *Cestoida* and *Cystica* combined; with the exception of the genus *Ligula* of Bloch, of which Cuvier makes a fourth order, restricting to it the application of Rudolphi's term *Cestoida*. To this distinction it must be objected that the passage from the *Tenia* to the *Ligula* is rendered very gradual by the traces of bothria and of generative organs, which make their appearance in the higher organised *Ligula* which infest the intestines of certain aquatic birds, and respecting which Rudolphi hazarded the hypothesis, viz. that these species are actually the more simple *Ligule* of fishes, developed into a higher grade of organisation by virtue of the warmth and abundant nutriment which they enjoy in the intestines of the birds that have swallowed the fishes so infested. Such migrations have since been experimentally proved in regard to many *Intestinalia*; especially in reference to the *Cystica*, Rud., which become *Cestoida* when introduced into other animals, as, e.g., from the flesh of prey into the gut of the devourer. The *Cystica* are, in fact, incompletely developed *Cestoida*.

Thus the intestinal worms, as at present known, form two classes, each divisible into three orders.

Class I. Cœlelmntha.

Order 1. *Nematoidea*.—Ex.: *Filaria medinensis*, *Fil. oculi*, *Fil. bronchialis*, *Ascaris lumbricoides*, *Asc. vermicularis*, *Trichocephalus dispar*, *Spiroptera hominis*. *Strongylus gigas*, *Strong. spiniger*: the *Trichina spiralis* is a larval Nematoïd, which acquires fully developed sexual organs when received into the intestinal canal, whence the progeny migrate to the muscular tissue.

Order 2. *Acanthotheca*.—Ex.: *Linguatula tenioides*.

Order 3. *Syngamoida*.—Ex.: *Syngamus trachialis*.

Class II. Sterelmntha.

Order 1. *Acanthocephala*.—Ex.: *Echinorhynchus gigas*.

Order 2. *Trematoda*.—Ex.: *Distoma hepaticum*, *Polystoma pingicula*, *Planaria*.

Order 3. *Teniodra*.—Ex.: *Bothrioccephalus latus*, *Tenia Solani*: the *Cysticercus cellulosa* and *Echinococcus hominis* are larval states.

The examples quoted are species which infest man, with the exception of *Planaria* and allied *Turbellaria*, Ehr., and of the orders *Acanthotheca*, *Syngamoida*, and *Acanthocephala*, which have no representatives among the human internal parasites. For the parts of the body which these latter infest, the reader is referred to ENTIZOA.

INTESTINE

(*Lat. intestinus, internal*). The convoluted membranous and muscular tube extending from the pylorus to the anus. It is distinguished, in the human subject, into small and large intestines: the former including the *duodenum*, the *jejunum*, and the *ileum*; the latter the *cæcum*, *colon*, and *rectum*. The small intestines have internal membranous folds, called *valvula conniventes*; the large have three parallel muscular bands upon their surface. The intestines admit of separation into three coats: the external, membranous or peritoneal; the middle coat, muscular; and the inner one, villous. They are attached to the body by the mesentery. The structure of the intestinal canal in different animals is adapted to its required functions, dependent upon the nature of their food and other circumstances. Of these peculiarities the principal are adverted to under the titles of the animals in which they occur.

Intonation (*Lat. in, and tonus, a tone*). In Music, the act of sounding, with the voice or an instrument, the consecutive notes of the scale, or in any other given intervals. To do this correctly is the first qualification of a good singer. It is scarcely practicable without the assistance of a good ear, as well as a reference to some common idea, such as the key or mode wherein a piece is written. From the word *tone*, sometimes used in a sense almost identical with that of *key*, the word has its origin.

Extrados (*Fr.*). The lower line of an arch; the outer or upper line being known by the name of the *extrados*. [*ARCH.*]

Intransitive (*Lat. intransitivus, from in, neg., and transeo, I pass over*). In Grammar, a word used to denote verbs expressive of actions of which the effects do not pass over to an object, as *I walk, I sleep*.

Intrenchment. In Fortification, a general term, denoting a ditch or trench with a parapet, for purposes of defence.

Intrinsic Equation (*Lat. intrinsecus, within*). The name proposed by Dr. Whewell in the *Cambridge Phil. Trans.* vol. viii for the equation which expresses the relation that exists between the length s of the arc of a curve, and the angle ϕ through which the tangent turns as its point of contact describes that arc. Thus if we suppose $f(\phi)$ to vanish with its argument ϕ , then the intrinsic equation of a curve will have the form $s = f(\phi)$. This granted,

$$\frac{ds}{d\phi} = f'(\phi)$$

will obviously be the expression for the radius of curvature, and the intrinsic equation of its evolute will be $s_2 = f'(\phi) - f'(0)$. [*EVOLUTE.*] The rectangular Cartesian equation of the curve is easily deduced from its intrinsic one. If both equations be referred to the same origin, and the initial tangent be taken as a scissæ axis, we have

$$dx = ds \cos \phi = f'(\phi) \cos \phi d\phi$$

and

$$dy = f'(\phi) \sin \phi d\phi;$$

240

INUNDATION

whence, by integration, we obtain two equations of the form

$$s = F(\phi, a) \text{ and } y = F(\phi, b),$$

from which by eliminating ϕ , the required equation, involving two arbitrary constants a and b , results.

The intrinsic equation of a curve may be advantageously employed in many enquiries, amongst which may be mentioned those relative to the successive involutes of a plane curve. [*INVOLUTE.*]

Introit (*Lat. introitus, entry*). In Ecclesiastical Antiquities, the verses chanted or repeated at the first entering of the congregation into the church; a custom as old as the fourth century: called *ingressa* in the Ambrosian Ritual. (Palmer, *Origines Liturgicæ*, ii. 19.)

Introrse (*Lat. introrsum, inwards*). In Botany, a term used in describing the direction of bodies to denote their being turned towards the axis to which they appertain; thus, in most plants the anthers are introrse, being turned towards the style.

Intrusion (*Lat. intrudo, I thrust upon*). In Law, a species of injury to freehold property. It arises when a stranger intrudes between the death of tenant for life or years and the entry of the heir of a remainder-man or reversioner expectant on the estate for life or years, who had died previous to the decease of such tenant for life or years. Writ of entry on intrusion was a special remedy for this injury, which having become obsolete was ultimately abolished by stat. 3 & 4 Wm. IV. c. 27.

Intuition (*Lat. intueor, I look into*). In Philosophy, any act of the mind by which a truth is immediately perceived, and as it were *beheld*, without any previous process of analysis or ratiocination. Such, according to Kant, are the fundamental propositions of geometry; as that 'two straight lines cannot inclose a space,' &c.

Intus-susception (*Lat. intus, within, and susceptio, a receiving*). In Anatomy, a term applied to the folding or passing of one portion of the intestinal canal into another.

Inula (*Lat.*). The Elecampane, long cultivated in herb-gardens, is the *I. Helenium* of botanists. It is a tall perennial herb, with large yellow composite flower-heads. Its root has an aromatic camphor-like taste, due to the presence of *helenin*, and contains also a quantity of starchy matter called *inulin*. Elecampane was at one time much used as an aromatic tonic and stimulant.

Inulin. An amylaceous substance contained in elecampane root. It differs from common starch in being rendered brown, instead of blue, by iodine.

Inundation (*Lat. inundatio, from unda, a wave*). In Agriculture, lands which are overflowed by water from natural causes uncontrolled by art, are said to be *inundated*: when in consequence of the exercise of art and skill, the result is termed *irrigation*.

INUNDATION. In Military Engineering, the

INVALIDS

flooding a portion of country with a view to its defence, by rendering it impassable for an enemy. This is an important element in the defence of fortresses.

Invalids (Lat. *invalidus*, *weak*). Those soldiers or sailors who, either on account of wounds or length of service, are admitted into hospitals, and there maintained at the public expense. The practice of making provision for soldiers worn out or disabled in the public service dates from high antiquity, and the veterans of the Roman legions were often rewarded with grants of land. But such rewards emanated more from individual power or favour than from any general or established principles of benevolence. In modern times there is no civilised country without institutions for the maintenance of invalids; but the most magnificent are the Greenwich and Chelsea hospitals in England, and in France the Hôtel des Invalides.

Invariable Plane. [ROTATION.]

Invariant. Any function of the coefficients of a system of quantics is said to be an *invariant* of that system when it is equal, to a factor *près*, to the function derived in a similar manner from the linearly transformed system of quantics. [COVARIANT AND CONCOMITANT.] The factor referred to is always a power of the modulus of transformation, and may be supposed equal to unity, in which case the transformation is said to be unimodular. [LINEAR TRANSFORMATION.] Thus the *resultant* of a system of equations is an invariant of that system, as may be seen *a priori*, inasmuch as the said resultant equated to zero expresses the condition that the equations should be satisfied by a certain set of values of the variables, and this property is obviously unaffected by linear transformation. Again, the *discriminant* of a quantic is necessarily an invariant, by the very nature of its formation. [DISCRIMINANT.] Of the many invariants of a quantic, a certain number are said to be *independent*; all others being expressible as rational integral functions of them. Thus, the binary quartic $(a_0, a_1, a_2, a_3, a_4) \chi(x, y)^4$, as Sylvester and Cayley have shown (*Phil. Mag.* April 1853, and *Phil. Trans.* 1855), has the two independent invariants

$$I = a_0 a_4 - 4a_1 a_3 + 3a_2^2,$$

$$J = a_0 a_2 a_4 + 2a_1 a_2 a_3 - a_0 a_3^2 - a_4 a_1^2 - a_2^3,$$

respectively called, for manifest reasons, the *quadrinvariant* and *cubinvariant* of the binary quartic. All other invariants of binary quartics can be expressed as rational functions of *I* and *J*; for instance, the discriminant, which is a *sextinvariant*, has the value $1^3 - 27J^2$. The sum of the suffixes of each term of either of the above invariants is visibly constant. This is a general property in virtue of which, and of certain differential equations which every invariant satisfies, any such function may easily be written down. The differential equations here referred to arise from the property which invariants, in common with covariants and the quantic itself, possess of giving the same

INVARIANTIVE OPERATION

results on applying the operations $y \frac{d}{dx}$, $x \frac{d}{dy}$, as they do under the application of the operations symbolised respectively by

$$\left[y \frac{d}{dx} \right] = \frac{d}{da_1} + 2a_1 \frac{d}{da_2} + 3a_2 \frac{d}{da_3} + \&c. \dots$$

$$\left[x \frac{d}{dy} \right] = -a_n \frac{d}{da_{n-1}} + 2a_{n-1} \frac{d}{da_{n-2}} + \&c.$$

[COVARIANT.] In the case of invariants the two former, and hence the two latter, results are manifestly zero. In his later researches, in fact, Prof. Cayley has defined an invariant as any function which is reduced to zero by each of the operations which, in the case of the original quantic, are tantamount to

$$y \frac{d}{dx}, x \frac{d}{dy} \&c. \dots$$

For further information on this very important subject, the researches of Cayley, Sylvester and others in the modern mathematical journals must be consulted; as an introduction to the subject, the *Lessons on the Higher Algebra* by Dr. Salmon will be found very useful. It may be here added that in geometrical applications, invariants equated to zero generally express the conditions under which a curve or surface will possess some permanent singularity, unaffected by the choice of axes, such as a double point, a conical point, and so forth. For instance, the discriminant

$$\begin{vmatrix} a, f, e \\ f, b, d \\ e, d, c \end{vmatrix}$$

of the ternary quadric $(a, b, c, d, e, f, \chi x, y, z)^2$, when equated to zero, expresses the condition that the conic represented by the latter breaks up into two right lines.

Invariantive Operation. An operation performed on a system of quantics, the result of which, after linear transformation of the variables which it may contain, is equal, to a factor *près*, to the result of the application of the same operation to the similarly transformed system. Thus it can be shown that the operations

$$\frac{d}{dx}, \frac{d}{dy}, \frac{d}{dz} \dots$$

are contragredient to $x, y, z \dots$ that is to say, if the latter are replaced by linear functions of themselves, the former must be replaced by the opposite or reciprocal linear functions of themselves; whence it follows that if

$$F(\xi, \eta, \zeta \dots)$$

be any contravariant of a quantic,

$$F\left(\frac{d}{dx}, \frac{d}{dy}, \frac{d}{dz} \dots\right)$$

will be an invariantive operation-symbol, and, according to the order of the contravariant, the result of operating upon the quantic with

INVASION

the symbol under consideration will yield a COVARIANT or an INVARIANT. [COVARIANT; CONTRAVARIANT; INVARIANT.]

Invasion (Lat. *invado*, *I enter*). The hostile advance of an army into an enemy's country.

Invention (Lat. *inventio*, from *invenio*, *to find*). In the Fine Arts, the choice and production of such objects as are proper to enter into the composition of a work of art. 'Strictly speaking,' says Sir Joshua Reynolds, 'invention is little more than a new combination of those images which have been previously gathered and deposited in the memory: nothing can come of nothing: he who has laid up no materials can produce no combinations.'

Invention of the Cross. A festival celebrated, May 3, in the Roman Catholic church, in honour of the finding of what was said to be the true Cross. The search was instituted by order of Helena, mother of the emperor Constantine, A.D. 316; and the cross, according to St. Cyril, was found among the ruins of Mount Calvary.

Inventory. A catalogue of movable goods, as of furniture, or the like.

Inverse Functions. The results of the performance upon the same subjects of INVERSE OPERATIONS.

Inverse Method of Fluxions. The method of finding the *fluents* of given fluxional expressions. It is the same with the integral calculus.

Inverse Method of Tangents. The method of finding the curve whose tangents are lines drawn according to some given law. The tangents to a given curve can be found by the differential calculus, whereas to find the curve which has given tangents requires the aid of the integral calculus. The two methods, therefore, are *inverse* to one another. A simple example of a problem of this nature is to find the curve upon whose tangents two fixed right lines intercept equal segments; for instance, the curve to which a ladder reared against a vertical wall is always tangential. The determination of the caustic by reflection or refraction from a given curve is also effected by this method.

Inverse Operations. In Mathematics, two operations are said to be inverse one of the other, when their successive performance on any subject leaves the latter unchanged; in other words, when the one destroys the effect of the other. Addition and subtraction, multiplication and division, involution and evolution, integration and differentiation, are, severally, examples of inverse operations. If ϕ denote any operation whatever, the symbol for the inverse operation would be ϕ^{-1} , and the two would be so related that $\phi[\phi^{-1}(x)] = x$.

Inverse Proportion. In Arithmetic and Algebra, two quantities are said to be inversely proportional to two others with which they are respectively associated when the first is to the second as the associate of the second is to that of the first. Thus A and B are inversely proportional to a and b when

INVERSION

$$A:B=b:a \text{ or } A:B=\frac{1}{a}:\frac{1}{b};$$

that is to say, when the ratio of A to B is the reciprocal of that of a to b , or, otherwise expressed, is equal to the ratio of the reciprocals of a and b .

Inversion (Lat. *inversio*). In Geometry, a peculiar method of transformation. Two points, pp' , are said to be inverse to each other, relative to a fixed point (*origin*) A, and a given fundamental quadric curve or surface (F), when they constitute a pair of conjugate points with respect to the latter, that is to say when the polar of one passes through the other, and when they are likewise collinear with A. Two curves, or surfaces, are said to be inverse to each other, when every point of the one has its inverse on the other.

Ordinarily, the fundamental curve (or surface) (F) is a circle (or sphere) whose centre coincides with the origin A. In this case the distances of inverse points from the origin are connected by the very simple relation $A.p.A.p' = k^2$, where k is the radius of the circle (or sphere) of inversion (F). Hence, metrical properties may be transformed by the simple formula

$$p'q' = \frac{pq}{A.p.A.q}, k^2,$$

where $p, p'; q, q'$ are any two pairs of inverse points. It may readily be shown that the inverse of a right line (or plane) is a circle (or sphere) through the origin, and vice versa; and further, that the inverse of every circle (or sphere) which does not pass through the origin is itself a circle (or sphere). Moreover, if any two curves whatever intersect at a point p , their two inverse curves will intersect at the inverse point p' in such a manner that the angles formed at p and p' will be equal to one another.

A plane figure and its stereographic projection, as is well known, possess the property just mentioned. [PROJECTION.] They constitute, in fact, a pair of inverse figures. Hipparchus, therefore, may be said to have first employed inversion. As a geometrical method, however, inversion is of recent date. Steiner, in his *Geometrische Gestalter*, and Magnus in Crelle's *Journal*, vol. viii., studied in 1832 a method of transformation of which inversion is a particular case. Plücker, in 1834 (Crelle's *Journal*, vol. xi.), established its descriptive properties; and Bellavitis, in 1836, developed its metrical properties in the *Memoirs of the Lombardo-Venetian Academy*. In England the method was first published (as new) by Mr. Stubbs in the *Philosophical Magazine* for 1843. Prof. W. Thompson applied it in 1845, in his 'Theory of Electrical Images' (*Cambridge and Dublin Mathematical Journal*), and was followed by Liouville, who published an elaborate memoir on the subject in his *Journal des Mathématiques* for 1847. The method of inversion which has been universally employed for the last ten years may be appropriately

INVERSION

termed *cyclical* (or *spherical*), and the more general method above defined may be distinguished as *quadric* inversion. (*Proc. of Royal Society*, March 1865.) There are still more general methods of inversion in which the fundamental quadric is replaced by a curve (or surface) of any order whatever; but these have been little studied.

INVERSION. In Music, the interchange of place between two notes of an interval; that is, placing the lower note an octave higher, or the higher note an octave lower.

INVERSION. In Rhetoric and Philology, the transposition of words out of their natural order. Every language has a customary arrangement of its own to regulate the order of succession in which words forming part of the same sentence, member, or proposition follow each other. On the other hand, there is undoubtedly a natural or philosophical order of words following each other in the same analytical succession in which ideas present themselves to the mind, varied occasionally by that produced by the succession of sentiments or emotions; and as in every language many customary phrases, if not the general arrangement of the words, are contrary to this primitive order, every language has customary inversions of its own. Deviations from the customary order of words are more commonly called *transpositions*; but each word has, of course, a relative and somewhat arbitrary signification. As an instance of ordinary inversion, it may be observed that, according to the metaphysical or analytical order, the subject of a proposition precedes the predicate, being the first idea which presents itself to the mind. Thus, in the construction of a sentence containing a proposition [Logic], 'Solon is wise,' or 'Alexander reigns,' we habitually follow the order of nature. But when a substantive and adjective in connection form part of a sentence, i.e. a subject or predicate, or a part of either, the substantive is that which seems naturally to present itself first to the mind; whereas in most modern languages it follows the adjective, while in the Greek and Latin its ordinary although not its necessary place was before it: 'Who is a wise man?'—'Vir bonus est quis?' 'The end of a long silence.'—'Silentii diuturni finis.' It is in general to be observed, that modern languages admit of transposition far less readily than the ancient; but there are considerable differences in this respect between modern languages themselves. German admits much latitude, French very little. In our own language we are frequently able to vary the analytical order by following what may be termed the order of emotion, where a French writer could not do so. Thus in the proposition 'Great is Diana of the Ephesians,' it would be impossible, in French, to give the force which is added to the expression by the transposition of the predicate to the beginning without violating the habitual rules of construction. A similar instance of inversion is to be found in the Swedish and some kindred

INVOCATION

languages, in which the article follows instead of preceding the noun.

Invertebrata (Lat. in, priv., *vertebra*, a joint of the backbone). The animals which are devoid of vertebrae, or of an internal bony skeleton, and which include the Molluscos, Articulate, and Radiate subkingdoms of *Animalia*, in Cuvier's system. Lamarck's primary division of the animal kingdom into *Vertebrata* and *Invertebrata* corresponds with that proposed by Aristotle into *Enaima* and *Anaima*. It is, however, subject to the objection which applies to most of the Dichotomous systems in Zoology; namely, that the two members of the division are not equivalent to each other. The *Invertebrata*, for example, contain three if not four primary divisions of the animal kingdom, each of which is equivalent to the *Vertebrata*.

Inverted Arch. In Architecture, one wherein the lowest stone, or brick, is the keystone. It is used in foundations, to distribute the weight of particular points, such as A, A, A, over the whole of the foundations; and hence its employment is frequently of the greatest importance in constructive architecture.

Investiture (Lat. *vestis*, a garment). In Feudal Law, the delivery of a fief by a lord to his vassal, accompanied by peculiar ceremonies. [FEUDAL SYSTEM.] The investiture of a bishop was, properly speaking, his endowment with the fiefs and temporalities of the see. Hence it became a subject of contest between the popes and emperors, and one of the principal grounds of the great quarrel of Guelfs and Ghibellines. It was conceded by the emperors to the Roman see in 1122; but the question was ended by a substantial compromise, which left the nomination in reality in the hands of the temporal prince. (Hallam's *Middle Ages*; Raumer's *History of the Hohenstauffen*; Gieseler's *Text-book of Ecclesiastical History*; Mosheim's *Ecclesiastical History*.)

Investment of a Fortress. The enclosure of a fortress on every side with troops, all the avenues to it being occupied, so as to prevent the garrison receiving supplies, or communicating with other troops. This is the first step necessary in a siege.

Invocation (Lat. *invocatio*, from *invoco*, I call upon). In Literature, signifies, in a general sense, an address, at the commencement of a poem, to the Muses or some other Being supposed to be capable of giving inspiration. Among the most beautiful invocations must be reckoned that which precedes the long catalogue of chieftains in the second book of the *Iliad*. The extreme solemnity of this invocation, and the extraordinary richness of imagery with which it is introduced, are among the strongest arguments for the oral transmission of the Homeric poems during a long series of ages. (Gladstone, *Homer and the Homeric Age* i. 246.)

INVOCATION OF SAINTS

Invocation of Saints. In Theology. According to Protestant writers, the veneration of saints and martyrs increased rapidly throughout the fourth century; but their *invocation* as intercessors with the Divinity did not generally commence much before the fifth. The followers of Origen are said to have been the first 'who apostrophised the martyrs in their sermons, and besought their intercession.' Prayers for the saints among other departed spirits were discontinued about the fifth century, on the principle laid down by Saint Augustine, 'Injuria est pro martyre orare, cuius nos debemus orationibus commendari.' [MARTYRS; SAINTS.]

Invoice (connected by Mr. Wedgwood with Ital. *avviso*, Fr. *avis*, a notice). A list or account of goods or merchandise sent by merchants to their correspondents at home or abroad, in which the peculiar marks of each package, with their value, customs, provision, charges, and other particulars, are set forth. (*Commercial Dictionary*.)

Involutum. In Botany, the secondary involucrum surrounding one of the umbellules of an umbelliferous flower, or the florets of a capitulum.

Involucrum (Lat. a *wrapper*). In Botany, a term applied to a ring or rings of bracts surrounding one or many flowers; also in describing ferns to denote the covering membrane which develops from beneath the sori; and in describing *Equisetacea*, to denote the cases of reproductive organs.

Involute (Lat. *involutus*, part. of *involvere*, I roll upon or enwrap). In Botany, when the edges of any organ are rolled inwards on each side, as occurs in the leaf of the apple.

INVOLUTE. In Geometry, the curve traced by any point of a flexible and inextensible string when the latter is unwrapped, under tension, from a given curve; in other words, the involute of a curve is the locus of a point in a right line which rolls, without sliding, over a given curve. This definition applies manifestly to the involutes of non-plane as well as of plane curves. The involute of every curve is an orthogonal trajectory of its several tangents, in fact a line of curvature on the developable osculatrix of that curve. An involute of a non-plane curve may be plane or non-plane; those of a plane curve, however, are all plane. The curve by unwrapping which a series of involutes is obtained, is said to be their common *evolute*, and any two involutes of a curve constitute a pair of *parallel curves*, their corresponding tangents being parallel, and their corresponding points, situated on the same normal, being equidistant.

The problem of finding the general equation of the involutes of a curve, is a particular case of the problem of trajectory, and requires the aid of the integral calculus; it is discussed in all good text-books. This problem is considerably simplified when one involute is given; it becomes identical then with the problem

INVOLUTION OF POINTS

of finding the parallel curves to the given involute.

The involute of an involute is called the second involute of the curve, the involute of this second is a third, and by proceeding in the same manner a whole series of involutes may be obtained. The properties of such a series have been little investigated. With respect to a series of plane evolutes, however, we are in possession of a remarkable theorem due in the first instance to John Bernoulli, but afterwards generalised by Euler (*Nov. Comm. Petrop.* 1764); according to this theorem the *ultimate involute of every curve is an epicycloid*. Demonstrations of this theorem have been given also by Poisson (*Jour. de l'École Polytechnique*, cah. 18), Legendre (*Exercices du Calcul Intégral*, t. ii.), Whewell (*Cambridge Phil. Trans.* vol. viii.), and Puisseux (Liouville, t. ix.). The theorem is also considered in Salmon's *Higher Plane Curves*. It should be observed, too, that the evolution of each involute is, in the above theorem, supposed to commence at the extremity corresponding to the termination of the preceding evolution. If the opposite method were pursued, and each evolution commenced at the extremity corresponding to the commencement of the preceding one, then the *rectilinear tail* of each involute being of the same length, the ultimate involute would be an arc of a logarithmic or equiangular spiral. (Dr. Whewell's *Memoir*; Boole's *Differential Equations*, p. 259.)

Involute of the Circle. The curve traced by the free extremity of a string as the latter is wrapped round a circle. The centre of the circle being the pole, and the radius (a) to the point where the wrapping ends being the polar axis, the equation of the involute in question is

$$\sqrt{r^2 - a^2} = a\theta + a \cos^{-1} \frac{a}{r}.$$

The first positive pedal of the involute is the spiral of Archimedes; its reciprocal is the hyperbolic spiral, which is the inverse of that of Archimedes. [PEDAL.]

Involution. In Arithmetic, the successive multiplication of a number by itself. The result of $n-1$ such successive multiplications is called the n^{th} power of the number. The number n is called the *index* or exponent of the power, since it indicates of how many equal factors the product or power consists. The n^{th} power of a quantity a is denoted by the symbol a^n ; thus $a^2 = a \cdot a$. It is evident, therefore, that $a^m \cdot a^n = a^{m+n}$. This is the simplest expression of the *index law*, common to many operations besides that of involution. Evolution, or the extraction of roots, is the operation *inverse* to involution.

Involution of Points or of Rays. When two rows of points are so related that each point of the first determines a single point of the second, whilst each point of the latter determines n definite points of the former, the first series is said to form an involution of the n^{th} order. If o represent any origin in

INVOLUTION OF POINTS

the first line, and a any point of the involution, the latter may also be defined by an equation of the form

$$h_1 \cdot \overline{oa}^n + h_2 \cdot \overline{oa}^{n-1} + \dots + h_n + \lambda (k \cdot \overline{oa}^n + k_1 \cdot \overline{oa}^{n-1} + \dots + k_n) = 0,$$

where $h_1, h_2, \dots, k_1, \dots$ are constant coefficients, and λ a variable parameter, which individualises each group of n points. Thus, if $A=0$ and $B=0$ be the Cartesian equations of two curves of the n^{th} order, the pencil of curves represented by $A + \lambda B = 0$ will cut the abscissa axis, or any line in the plane, in a system of points forming an involution of the n^{th} order. Involutions of the second order have been hitherto almost exclusively studied; their properties are considered in Salmon's *Conic Sections*, in Mulcahy's *Principles of Modern Geometry*, and in Townsend's *Chapters on Modern Geometry*. The above generalised definition was given by De Jonquières, and probably suggested by the analogous definition of a quadratic involution first given by Chasles, *Comptes Rendus*, Dec. 24, 1855.

An involution of the first order is, of course, a simple series of points, and any involution whatever is manifestly determined by two groups. In general there are $2(n-1)$ of these groups which contain two coincident points; these are the *double points* or *foci* of the involution. They are found, of course, by equating to zero the discriminant of the preceding equation, which discriminant is well known to be of the $2(n-1)^{\text{th}}$ degree in λ . [DISCRIMINANT.] The group which includes the point at infinity amongst its constituents is called the *central group*, each of its points is characterised by the property that the product of its distances from the n points of any other group is invariable. Thus, in an involution of the second order, if o denote the point whose conjugate is at infinity, and a_1, a_2 the two points which constitute any other group, $oa_1 \cdot oa_2 = \text{const.}$ From this it follows at once that an involution of the second order results from two homographic rows of points so superposed that the point of each row which corresponds to infinity on the other coincides with one and the same *central point* o . [HOMOGRAPHIC.] It is obvious, too, that in an involution of the second order the anharmonic ratio of any four points is equal to that of their four conjugates. If in any involution whatever, the harmonic centre be taken, with respect to any pole, of the points of each group, a row of points will be obtained which will be homographic with any similar row of centres taken with respect to a different pole. The anharmonic ratio, therefore, of the harmonic centres, of the first order, of any four groups is invariable, no matter what pole may be chosen. This ratio is called the *anharmonic ratio of the four groups*, and if these groups correspond to the values $\lambda_1, \lambda_2, \lambda_3, \lambda_4$ of the parameter λ , the ratio is expressed by

$$\frac{\lambda_1 - \lambda_2}{\lambda_3 - \lambda_4} : \frac{\lambda_1 - \lambda_4}{\lambda_2 - \lambda_3}.$$

IODINE

Two involutions of the orders m and n , respectively, are said to be homographic when the harmonic centres, with respect to any pole, of the groups of the one, and the harmonic centres, with respect to the same or any other pole, of the groups of the other, form two homographic rows of points. It follows, then, from the above definitions that the groups of two homographic involutions correspond *anharmonically*; that is to say, the anharmonic ratio of any four groups of the one is equal to that of the corresponding groups of the other. When two homographic involutions of the orders m and n are superposed, there are in general $m+n$ common points, that is to say points with each of which coincide constituents of corresponding groups. Two superposed involutions of the same order, higher than the second, have not in general a common group; they can never, of course, have two common groups. Two superposed quadratic involutions, however, have in general a common group.

The rays of a plane pencil are also said to form an involution of the n^{th} order when they intersect any transversal in an involution of points of that order.

Io (Gr. *Ἰώ*). In Greek Mythology, this mythical being is the subject of a very large variety of legends. According to one of the most popular versions, she was a daughter of Inachus, king of Argos. The love of Zeus for this maiden roused, as in other myths, the jealousy of Hera, who transformed Io into a heifer, and placed her in the charge of Argos Panoptes. This guardian was slain by Hermes, who was thence called Argeiphontes, or the Slayer of Argos. Hera then sent a gadfly, which stung the heifer and drove her in madness over the earth. Thus began those wanderings of Io which Æschylus has sketched in his drama of *Prometheus Chained*. The tale of Io is thus connected with the legend of Epaphus, the calf-god (identified by Herodotus with the Egyptian Apis), and also with the myths of Heracles, of whom, according to the prophecy of Prometheus, she was to be an ancestor.

Iodates. Salts of the iodic acid.

Iodine (Gr. *ἰώδης*, violet-coloured). A substance discovered in 1812 by M. Courtois of Paris. In this country it is usually prepared from kelp, which is lixiviated with water; and, when the crystallisable salts have been separated, the mother liquors are mixed with sulphuric acid and black oxide of manganese. On the application of heat the iodine rises in the form of a dense violet-coloured vapour, which by condensation forms steel-gray crystals looking like micaceous iron. The specific gravity of iodine is between 4 and 5; when dry it fuses at 227° , and boils and evaporates in purple fumes at 345° . When heated with water it distils over at temperatures below 212° . The specific gravity of its vapour is about 8.7, so that 100 cubic inches would weigh nearly 276 grains. Iodine belongs to the electro-negative supporters of combustion. It has an acid taste, and a peculiar odour somewhat like

IODIDE

that of chlorine. It is an irritant poison ; but in small doses, and cautiously administered, it has occasionally been of great service in certain forms of glandular disease. It is very sparingly soluble in water, of which it requires 7,000 parts for its solution ; the colour of the solution is brown : it dissolves copiously in alcohol and in ether, and forms dark-brown liquids. It possesses strong powers of combination, forming, with the metals, a class of compounds called *iodides* ; with oxygen it forms the *iodic acid*, and perhaps one or more oxides. Combined with hydrogen, it forms the *hydriodic acid*. Its equivalent number is 126, and that of the hydriodic acid 127. Starch is a characteristic test of the presence of free iodine, forming with it a compound of a deep blue colour. It is so delicate that a solution of starch dropped into water containing less than a 400,000th part of iodine, is tinged blue by it ; but the solutions must be cold, for the blue compound disappears in hot water. The great consumption of iodine is in medicine ; it is chiefly employed in the form of *iodide of potassium*, which is obtained by dissolving iodine in a solution of pure potash, evaporating to dryness, and fusing the residue.

Iodide. Native iodide of silver. It occurs in hexagonal crystals, and in thin plates of a greyish or silver-white colour, at Guadalupe in Spain, Albaradon in Mexico, and at the Delirio mines of Chañarcillo in Chili.

Iodoform. A substance in the form of yellow scales, produced when alcohol, iodine, and potash are brought together.

Iodoquinine. An organic substance formed on rubbing quinine with iodine. The bisulphate of iodoquinine may be obtained in large lamellar crystals, which perfectly polarise light.

Iodite (Gr. *ior, violet*). A mineral of a violet-blue colour by transmitted light ; it occurs crystallised, and in small grains and rolled masses.

Ionic Dialect. This most euphonious of the four written varieties of the Greek language, was spoken by the inhabitants of the Ionian Islands, and in their colonial possessions in Asia Minor. The chief writers in the Ionic dialect are Herodotus, Hippocrates, and Galen ; but it is in the writings of the first that the most complete specimen is to be found.

Ionic Order. One of the five orders of Architecture, of which the distinguishing feature is the volute of its capital. In the Grecian Ionic, the volutes appear the same in the front and the rear, being connected in the flanks with a kind of baluster-like form ; though in the external angles of the inner columns a diagonal volute is introduced. The Romans made their Ionic capital with four diagonal volutes, and they curved the sides of their abacus. The Greek volute continues the fillet of the spiral along the face of the abacus ; whereas in the Roman order its origin is behind the ovolo. In some Grecian examples, a neck is added below the echinus, sculptured with flowers and leaves. The height of the column

IONIC PHILOSOPHERS

is about nine diameters, and the base varies greatly in different examples. When a pedestal

is used, it is somewhat higher, and more ornamented, than the Doric pedestal. The Greeks usually made the entablature of this order very simple ; the architrave has two fasciæ, the frieze is plain, and the cornice of few subdivisions ; but the modern Ionic has seldom less than three fasciæ in the architrave ; the frieze is often cushioned, and the cornice is deeper and not unfrequently modillioned, its profile being much varied. The dentil is also much used in the bed mouldings. The shaft is cut into twenty-four flutes, separated by fillets. Some of the most celebrated examples of the order are the temple on the Ilyssus, of Athena Polias at Athens, of Bacchus at Teos, and of Fortuna Virilis at Rome. The profile above given is after Palladio.

being much varied. The dentil is also much used in the bed mouldings. The shaft is cut into twenty-four flutes, separated by fillets. Some of the most celebrated examples of the order are the temple on the Ilyssus, of Athena Polias at Athens, of Bacchus at Teos, and of Fortuna Virilis at Rome. The profile above given is after Palladio.

Ionic Philosophers. The earliest among the Greek schools of philosophy. Speculation arose in Greece, as elsewhere, in the attempt to discover the laws of outward phenomena, and the origin and successive stages of the world's developement. Such an attempt, it is needless to say, must at first have been extremely rude. But to the student of philosophical literature no such undertaking, however unsuccessful, can possibly be otherwise than interesting ; and in this instance in particular we are able to discover manifest traces of that liveliness of thought and systematic spirit which distinguish the later Greek speculations. The fathers of the Ionic school were Thales and his disciple Anaximenes. They were succeeded in the same line of thought by Diogenes of Apollonia and Heraclitus of Ephesus. The characteristic mark which distinguishes the speculations of these thinkers is the endeavour to refer all sensible things to one original principle in nature. The two first named were satisfied with a very simple solution of the problem. Water with the one, and air with the other, were made the original materials out of which all things arose, and into which they were finally resolved. In their successors the germs of a more philosophical doctrine are apparent. They retain, indeed, the simplicity of an original element ; but the air of Diogenes and the fire of Heraclitus are apparently only sensible symbols, which they used only in order to present more vividly to the imagination the energy of the one vital principle which is the ground of all outward appearances. It

IONIDIUM

would indeed be a mistake to regard these philosophers as *materialists*. The distinction between objective and subjective, between a *law* operating in the universe and the corresponding apprehension of that law by reason, however obvious it may seem at the present day, seems to have required the deep meditation of numerous powerful thinkers to bring it into clear consciousness.

That the two things were confounded by Heraclitus is evident from his attributing to this universal fire the attributes of a universal reason—the source at once of the order in the world, and of the insight into that order possessed by man. Notwithstanding this confusion, the discovery is due to him of the important truth, that 'reason is common to all men'—that the ultimate principles of science derive their validity from their universality; a truth the value of which is not diminished by our finding it combined with the physical hypothesis of which we have spoken.

The philosophers enumerated above may be considered as forming one division of the Ionic school. They agree in regarding the universe as the result of the spontaneous evolution of a single principle or power; and all sensible things as modifications of this principle, real only in reference to their ultimate ground. But we meet also with a class of thinkers in whom the contrary tendency prevailed. Anaximander, a contemporary of Polycrates, and Anaxagoras, the master of Pericles, agree in this respect, that they consider the world to be made up of various small particles, of different kinds and of various shapes, by the change in whose relative position all phenomena are to be accounted for. This hypothesis is combined by Anaxagoras with a Supreme Reason, the author of all that is regular and harmonious in the disposition of these elementary atoms. Anaxagoras may indeed be considered, as the first philosopher who clearly and broadly stated the leading distinctions between mind and matter. For a statement at once luminous and accurate of the leading peculiarities of this philosopher's doctrines, and those of his predecessors, see Thirlwall's *History of Greece*, vol. ii. chap. xii. The student who wishes for more minute information may consult Brandis and Ritter's *Histories of Philosophy*; the 'Fragments of Heraclitus' in Wolf and Buttmann's *Museum of Antiquities*; and the *Mémoires de l'Académie des Inscriptions*, vol. xvii.

Ionidium (Gr. *ion*, a violet, and *eidōs*, likeness). A genus of South American *Violaceæ*, some of whose species contain emetin, and may therefore be used as *Ipecacuanha*. The roots of *I. ipecacuanha* form White *Ipecacuanha*, while those of *I. microphyllum*, which act powerfully as emetics and purgatives, are famed in Peru for the cure of tubercular elephantiasis. Other species also possess medicinal properties.

Ipecacuanha (Peruv. *ipe*, root, and *cacuan*, a native distinction for this root). The root of the *Cephaelis Ipecacuanha*. This im-

IRIDACEÆ

portant article of the *Materia Medica* is the produce of South America; it is found in short wrinkled pieces, covered with a grey or brownish grey epidermis, and having a central woody fibre, surrounded by a pale grey cortical part, in which its virtue resides. It has a nauseous odour, and a repulsive, bitterish taste. It is not easily reducible to powder; and the dust which it throws off, whilst under the process of pulverisation, is apt to excite great irritation of the respiratory organs. From fifteen to twenty grains of powdered *ipecacuanha* root taken in an ounce of water, is one of the safest and surest *emetics*; in doses of from one to three or four grains, it is a *nauseant*; and in smaller doses, repeated every four or six hours, as from a fourth of a grain to a grain, it is expectorant and diaphoretic. It contains from twelve to sixteen per cent. of *emetin*, to which its medical activity is referable. When long boiled with water, its emetic power is diminished, but the decoction is aperient. There are several varieties of *ipecacuanha*, some of which arise from modifications of soil and climate; others appear to be the roots of distinct plants. Among the latter are the roots of *Psychotria emetica*, *Ionidium Ipecacuanha*, *Boerhaavia decumbens*, and *Richardsonia scabra*.

Iphigenia. [THESEUS.]

Ipomœa (Gr. *ipō*, a worm, and *moios*, like).

A large genus of the order *Convolvulaceæ*, comprising many species of great beauty, and some of much utility. Several of them yield Jalap, or analogous substances, though the best Jalap comes from *Erogonium*: among these *I. Turpethum*, *pandurata*, and *batatoides* may be particularly mentioned.

Iriarteia (after Iriarte, a celebrated Spanish botanist). This genus of South American palms well illustrates a curious habit in certain plants of the palm family, that of elevating their trunks, as it were, entirely above ground, on a conical mass of cylindrical roots. In *I. exorrhiza*, the *Paxiuba* palm of Brazil, the cone of roots is sometimes so high that a man can stand in the centre, with the tall tree above his head. The exposed roots are covered with little asperities, and are hence used by the Indians as graters, while the hard outer wood is used for their houses, and also for making umbrella handles.

Iriartella (after Iriarte). The South American palm formerly named *Iriarteia sciogra*, which grows twenty feet high, with a perfectly straight cylindrical trunk, scarcely more than an inch thick. From this trunk the Indians form their blow-pipes, through which they blow small poisoned arrows to a considerable distance.

Iridaceæ (*Iris*, one of the genera). A natural order of herbaceous Endogens, inhabiting the Cape, and some other places. It differs from *Amaryllidaceæ*, essentially, in being triandrous, with the anthers turned outwards; from *Orchidaceæ*, in not being gynandrous; and from *Zingiberaceæ* and *Marantaceæ*, in having three perfect stamens. The species are more remark-

able for their beautiful flowers than for their utility. The substance called saffron is the dried stigmata of the *Crocus sativus*. The various species of *Iris*, *Ixia*, *Gladiolus*, *Tigridia*, *Crocus*, &c. are among the favourite flowers of the gardener.

Iridæa (Gr. *Iris*, the rainbow). One of the edible Seaweeds, belonging to the rose-spored division. *I. edulis*, which is sometimes eaten like common dulse, is known by its tough obovate dark red frond, which is wedge-shaped at the base. It has been used as dye, but its colour appears to be fugitive.

Iridescent Films. Iridescent films are produced by dropping a little oil or spirit varnish upon the surface of water contained in a vessel. When the water becomes tranquil, the varnish spreads in all directions, becoming exceedingly attenuated, and reflects the most vivid colours of the spectrum. If any objects that require ornamenting, such as insects, shells, birds, bronzes, paper-hangings, &c., are previously immersed in the water, and slowly raised to the surface, after the film has been formed, the latter will adhere to their surfaces, and when they are completely dried it will be found firmly attached to them, and perfectly iridescent, having lost nothing of its brilliancy of colouring. This is a beautiful illustration of the production of colours on a thin transparent and colourless surface, by the agency of light, such as is seen in an ordinary soap bubble. [INTERFERENCE.]

Iridocyanogen. The supposed negative radicle of a double salt of cyanide of iridium and of potassium.

Iridium (Gr. *Iris*, the rainbow, in consequence of the variety of colours exhibited by its solutions). A metal discovered by Dr. Wollaston, associated with the ore of platinum. It is grey, brittle, very difficult of fusion, and its specific gravity is about 18.6. It forms several oxides and chlorides, and combines readily with carbon.

Iridosmine or **Irid-osmium**. Native osmide of iridium, in which the iridium is more or less replaced by platinum, rhodium, and ruthenium. It generally occurs in small irregular flattened grains, harder, heavier, and of a rather paler steel-grey colour than native Platinum, with which it is found, in the province of Choco in South America; in the Ural Mountains of Siberia; in the alluvial gold of California; Australia, Borneo, &c. Iridosmine is also known by the name of Native Alloy.

Iris (Lat.; Gr. *Iris*). In Anatomy, the anterior part of the *obscure* coat of the eye, with superadded muscular fibres. Its central perforation is called the *pupil*; the posterior part or back of the iris is called the *uvea*. The term *iris* is applied to that part of the eye on account of its various colours. [EYE.]

Iris. In Astronomy, one of the newly discovered planets of the group between Mars and Jupiter.

Isarn. In Botany, the name of a very beau-

tiful genus of plants, typical of the *IRIDACEÆ* [which see].

IRIS. In the Homeric Mythology, *Iris* is the messenger of the gods who carries messages from Ida to Olympus, or from the gods to men. In the Hesiodic *Theogony*, she is a daughter of Thaumas and Electra, and a sister of the HARPIES. According to later versions, she was married to Zephyrus, and became the mother of Eros. This legend gives, perhaps, some ground for connecting the names *Iris* and *Eros*, together, with the Vedic *Arusha*. In the *Iliad* the rainbow also was called *Iris*; but the personification of *Iris* as the goddess of the rainbow seems to be of later growth.

IRIS. The name given by French jewellers to limpid and transparent stones, but chiefly to Rock Crystal when reflecting prismatic colours like Opal, by means of natural internal flaws. Common Rock Crystal is sometimes artificially converted into iris, but in these cases the fissures are produced in the outer part of the stone instead of being in the interior. Imitation iris has lately made its appearance in the London shops, made into sleeve-buttons, solitaires, &c. under the name of *Pierre des Alpes*, &c.

Iriscope (Gr. *Iris*, and *σκοπεω*, I view). An instrument proposed by Dr. Joseph Roade for exhibiting the prismatic colours, thus described by Sir David Brewster, in the *Phil. Trans.* for 1841: 'This instrument consists mainly of a plate of highly polished black glass, having its surface smeared with a solution of fine soap, and subsequently dried by rubbing it clean with a piece of chamois leather. If we breathe upon the glass surface, thus prepared, through a glass tube, the vapour is deposited in brilliant coloured rings, the outermost of which is black, while the innermost has various colours, or no colour at all, in proportion to the quantity of vapour deposited. The colours in these rings, when seen by common light, correspond with Newton's *reflected* rings, or those which have black centres, the only difference being, that in the plate of vapour, which is thickest in the middle, the rings in the iriscope have black circumferences.'

Irish Moss. The *Chondrus crispus*. [CARRAGEEN MOSS.]

IRITE. A mineral found in octahedrons and in lustrous black scales, which are attracted by the magnet, filling up interstices in the platinum of the Ural.

According to Hermann, it is a compound of the peroxides of iron and chromium with the protoxides of osmium and iridium; but Claus considers it to be merely a mechanical mixture of several substances, chiefly iridosmine and chromic iron.

IRITIS. Inflammation of the iris of the eye.

IRON (Sancr. *ayas*, probably at first the *metal*, i.e. copper, although in Sanscrit the word is confined almost exclusively to iron; Lat. *æs*, *brass*; Old High Ger. *ær*, *bronce*; Goth. *eisarn*, iron, changed in Old High Ger. to *isarn* and

IRON

Isan = Mod. Ger. eisen, while the A.-Sax. *tern* leads to *iron* and *iron*: Max Müller, *Lectures on Language*, second series, p. 233). This important metal is largely diffused in the state of oxides and carbonates; it is also found combined with sulphur, and with several acids, and is a common component of many minerals. It occurs in small quantity in some animal and vegetable bodies, and mineral waters, and it forms the principal component of many meteoric stones. Its chemical symbol is Fe, and its equivalent or atomic weight is 28.

Manufacture of Iron.—The argillaceous iron ore of the coal-measures is the principal source of British iron. It occurs in nodules and seams, alternating with coal, shale, and limestone, and contains from 70 to 80 per cent. of carbonate of iron, the remainder being chiefly clay and carbonate of lime. It is first roasted, either in kilns or heaps, and, mixed with coke and limestone, is subjected to the intense heat of the blast-furnace; these materials being successively thrown in from above, and gradually descending till they reach the lower or hottest part. In their descent the iron is reduced, and in combination with a portion of carbon falls through the fused slags to the bottom of the furnace, whence it is withdrawn at intervals, by opening the *tap-hole*, while the slags are allowed to run off by an aperture left for the purpose: they consist chiefly of the silicates of lime and alumina, with smaller proportions of the silicates of magnesia, manganese, and iron.

The smelting furnaces are usually about 50 feet high, and 15 feet in the widest part of their internal diameter; they are constructed of strong masonry and brickwork, and lined with the most refractory fire-stone. They are worked day and night for several successive years, air being supplied to them by powerful blowing machines, generally so constructed as to throw it in in a heated state, or as a *hot blast*, and to the amount of about six tons weight per hour. It is estimated that by the use of hot instead of cold air, a very large saving of fuel is effected. With the cold blast, about eight tons of coal are consumed in the production of a ton of iron; whereas with the hot blast, less than three tons are sufficient, and with it coal may be substituted for coke. These furnaces are usually tapped night and morning, furnishing from eight to ten tons of metal daily, and requiring an hourly supply of about a ton and a half of the mixture of roasted ore, limestone, and coal or coke. The melted metal is suffered to run into rough moulds of sand, and in this state constitutes the *cast* or *pig iron* of commerce.

There are several varieties of cast iron, but they are commercially distinguished as 1. *grey*, 2. *mottled*, and 3. *white*. They are all *carbides*, and the grey and mottled varieties include a portion of graphite diffused through them, which remains undissolved and unchanged after the action of dilute sulphuric

acid, whilst the greater part of the combined carbon unites to the hydrogen, forming hydrocarbons. Cast iron also contains silicon, phosphorus, manganese, and traces of calcium, aluminium, and sulphur.

Grey cast iron is soft and somewhat tough; it admits of being bored, and turned in the lathe. When immersed in dilute hydrochloric acid it leaves a black insoluble residue; its texture resembles bundles of small needles. *Mottled iron* is coarser grained, and small particles of graphitic carbon may be discerned in its fracture. *White cast iron* is very hard and brittle; acids act but slowly upon it, and develops a lamellar rather than a radiated texture: it sometimes contains as much as five per cent. of carbon, so that it is nearly represented by Fe_3C , and may be regarded as iron saturated with carbon.

When small articles of cast iron are bedded in oxide of iron (powdered hematite is generally used), and kept for some hours at a red heat, they are to a great extent decarbonised, and so far softened as to resemble wrought iron, especially when they are slowly cooled. In this operation the carbon of the cast iron appears to be gradually removed, in the form of carbonic oxide, at the expense of a part of the oxygen of the oxide in which they are embedded.

Wrought or malleable iron is the metal in a comparatively pure state, though it retains traces of carbon, and of some of the other impurities of cast iron. To effect the conversion of cast into wrought iron, the cast metal is in the first instance *refined*, by subjecting it to the action of air at a very high temperature, in a kind of forge furnace. Much of the carbon is thus burnt off; and the silicon, converted into silica, forms a fusible slag with the oxide of iron, which tends to the further purification of the mass. The fused metal is then run off, and formed into cakes, which are rapidly cooled by the effusion of water. The silicate of iron formed in this process is partly derived from the rough cast iron, and partly from added sand; it approaches the composition $3(\text{FeO})\text{SiO}_2$, and itself performs a part in cleansing the metal, by acting as an oxidising agent. The further and final purification of the metal is effected by a process called *puddling*, carried on in a reverberatory furnace, which admits of the fusion of the refined iron by a current of intensely heated air and flame, without direct contact with the fuel. Here the metal is well stirred, so that the superficial oxide may be mixed in the mass, which soon begins to heave and emit jets of carbonic oxide, and gradually growing tough and less fusible, becomes at length pulverulent. The fire is then urged so that the particles again agglutinate at a welding heat, and admit of being made up into globular masses, or *blooms*, and in that state of intense heat are subjected to the *slinging press*, or to *rollers*, by which extraneous matters are squeezed out in the form of slag, and the density of the metal

IRON

increased; it now admits of being rolled into bars, which are cut into convenient lengths, placed in parcels in a very hot reverberatory furnace, and again rolled. The metal is now tough, flexible, and malleable, but less fusible, and is, in fact, nearly pure, retaining not more than $\frac{1}{100}$ part of carbon, and traces only of other matters.

The slags formed in the operations of refining and puddling, containing about sixty per cent. of iron, are reduced in the blast furnace, in the same way as the original ore, but the iron so produced is *cold short*; it admits of working at a red heat, but is brittle when cold, a quality supposed to depend upon the presence of phosphide of iron, derived from phosphate of iron existing in the slag. Iron is also occasionally *red short*, that is, brittle at a red heat, though malleable when cold: this quality has been ascribed to traces of arsenic and copper.

Many other processes for the conversion of cast into wrought iron have been suggested, and amongst them that of Mr. Bessemer deserves especial mention; it consists in passing currents of air and steam through the fused metal. For details upon these subjects the reader is referred to Percy's *Metallurgy*; to Ure's *Dictionary of Arts and Manufactures*; and to the article 'Iron' in Watt's *Dictionary of Chemistry*.

At what period iron began to be made in this country, there is no means of ascertaining; but there is authentic evidence to show that iron works were established by the Romans in the Forest of Dean and in other parts of the kingdom. (Pennant's *Wales*, vol. i. page 80, ed. 1810.) They were also established at a very early period in Kent and Sussex; but it was not until after the celebrated invention of Lord Dudley in 1619, by which pit coal was substituted for wood in the smelting of iron ore, that a great impetus was given to the working of this valuable mineral; an invention which, though interrupted and clogged for a time by the devices of an ignorant rabble, at last established for itself a sure footing both in this and in every other country in the civilised world. From 1740 (the date when Lord Dudley's invention became generally adopted), the progress of the manufacture, in England, has exceeded the most sanguine expectations; and though we have no means of ascertaining the exact quantity produced, the subjoined estimates will show at one glance the importance of the manufacture, and the unexampled rapidity of the growth of this branch of the national production during the last and the present centuries. In 1740 the quantity of iron manufactured in England and Wales was only 17,000 tons; in 1750, it was 22,000 tons; in 1788, it was 68,000 tons; in 1796, it was 125,000 tons; in 1806, it was 250,000 tons; in 1820, it was 400,000 tons; in 1827, it was 690,000 tons; in 1840, it was 1,000,000 tons; in 1850, it was nearly 2,000,000 tons, and in 1857 it was estimated that the total production of England was about 3,000,000 tons of crude

iron. The other nations have made great advances in appropriating the most economical processes of the conversion of iron; but they have not hitherto more than equalled the production of England.

Properties.—Iron is fusible at a white heat, but with great difficulty when perfectly pure. It requires the highest heat of a wind furnace to run down soft iron nails into a button, and therefore a temperature equal to about 3,300°. Its sp. gr. is 7·8. Its texture varies with the method of working: in bars or wires it appears longitudinally fibrous, but when long kept at a red heat it acquires a crystalline texture, and a tendency to cuboidal fracture. It is the hardest and toughest of the ductile metals; it may be drawn into fine wire, but cannot be hammered out into thin leaves; it is very tenacious; and at a bright-red or orange heat it admits of being *welded*, or joined by hammering, to another piece of the red-hot metal. It is attracted by the magnet, but does not retain magnetism when pure; at a bright-red heat it becomes indifferent to it, but reacquires this property on cooling.

To obtain pure iron, filings of the best bar-iron may be mixed with about one-fifth their weight of pure peroxide of iron, and exposed (covered with pounded glass quite free from lead) in a well-closed crucible, for about an hour, to the strongest heat of a forge. Exposed to heat and air, iron becomes superficially converted into a fusible oxide; when exposed to a damp atmosphere, it becomes incrustated by a brown *rust*. When in a state of extreme division, its affinity for oxygen is such, that it heats, and even ignites, on exposure to air; this is the case with the metal as obtained by the action of hydrogen upon red-hot oxide of iron, and when thus reduced, at a temperature not sufficient to cause the adhesion of the particles of the metal, and suffered to cool in an atmosphere of hydrogen, it requires the same precautions for its preservation as potassium. A spontaneously combustible form of iron is also obtained by the ignition of Prussian blue. In a dense mass, iron is not affected by dry air, and it even retains its polish when immersed in pure water which has been deprived of air; but in common water, or in water exposed to air, it soon rusts. This oxidisation by water is prevented by the alkalies; and in lime water, or in a weak solution of ammonia, potash, or soda, the metal keeps its lustre.

Iron is susceptible of four definite degrees of oxidisation—forming a *protoxide* (FeO), which has not been isolated, but which is the basis of a series of well-defined salts; a *sesquioxide* (Fe_2O_3), generally termed *red oxide* or *peroxide*; a *black intermediate oxide*, known also under the name of *magnetic oxide* (Fe_3O_4), and a *hyperoxide*, called *ferric acid* (Fe_2O_5), but which, like the protoxide, has not been isolated.

The oxides of iron are the common colouring matters of the mineral kingdom; the peroxide is much used as a pigment, and in the

IRON ARMOUR PLATES

state of *hydrate* for the purification of coal gas by the abstraction and decomposition of sulphuretted hydrogen. The compounds of iron with chlorine, &c., generally correspond in atomic composition with the protoxide and peroxide. The sulphides are represented by FeS and FeS_2 : there is also a sesquisulphide $= \text{Fe}_2\text{S}_3$. [PYRRHUS.]

Many of the salts of iron are of much importance in the arts, more especially as mordants in dyeing and calico printing, in the manufacture of common writing ink, of Prussian blue, and of several pharmaceutical preparations: the principal of these will be found noticed under other heads. The presence of iron in water is recognised by its inky taste, by the deposition of a yellow or brown precipitate when boiled or exposed to air; by a purple or black tinge with infusion of galls, and a blue tinge with ferrocyanide of potassium. The salts of the protoxide are mostly converted into those of the peroxide, by exposure to air, or by common oxidising agents.

Iron Armour Plates. Plates used for the protection of vessels of war, and fortifications, against modern artillery. Although iron armour was suggested in America in 1812, and in France in 1821, the first English experiment recorded took place at Woolwich in 1827, at the instigation of General Ford, who proposed to protect masonry with wrought-iron bars. The result of this experiment being unsatisfactory, the idea was abandoned; and though revived again in this country in 1850, it was first brought to a practical issue in France. The French floating battery, engaged at Kinburn in 1855, was so superior to its wooden companions, that the question of iron defences was taken up by our Admiralty. A committee assembled, and carried on experiments until 1860, which ended generally in this result: That a good wrought-iron plate, $4\frac{1}{2}$ inches thick, backed with 18 inches of teak, was practically proof against the 68-pounder and 7-inch breech-loader Armstrong gun, at a range of 400 yards. On the data thus obtained, the Warrior, Black Prince, Defence, and Resistance, were built, their construction being as follows: $4\frac{1}{2}$ -inch wrought-iron plates, each 15 feet by 3 feet 2 inches, fastened by $1\frac{1}{2}$ -inch bolts, riveted on the inside; then a backing of 18 inches of teak well caulked, and a $\frac{3}{4}$ -inch wrought-iron skin on iron ribs, 18 inches apart. The bow and stern of the Warrior and Black Prince are covered with only $\frac{3}{4}$ -inch boiler plate, in order to lessen the weight.

A new committee was appointed early in 1861, which continued its labours until early in 1864, during which period very heavy guns were made, and brought to bear upon armour-plated targets of various constructions. The following are the chief results established by this course of experiments.

1. Wrought iron of the softest quality is best adapted for armour plate; and the least approach to steely quality of iron should be avoided. 2. Very powerful machinery is abso-

lutely necessary, and rolled plates are better than hammered. 3. Large and wide plates are better than small and narrow, all plates being weakest near the edges. 4. Tongueing and grooving weakens the plate, and tends to destroy the plate adjacent to that which is struck. 5. A combination of bars is inferior to a solid plate of the same weight or thickness. 6. A series of thin plates is similarly inferior. 7. Generally, no combination is so good as a solid plate, the resistance of which, up to a certain point, may be assumed to be nearly as the square of the thickness. 8. No advantage is gained by placing plates at an angle if the iron must be made thinner in consequence; or, in other words, iron of a given weight is most usefully employed in thick vertical plates. 9. Rigid backing is best for fortifications, but a soft backing yields to any distortion of the plate, distributes the effect over a larger area, and diminishes the damage to the general structure. 10. Wooden backing answers these conditions as well as, or better than, any other. 11. Increase of thickness of plate does not compensate for considerable diminution of backing. 12. All irregularities of surface, such as bosses, &c., tend to weaken the plate. 13. A facing of wood, or other material, saves the plate to some extent; but is easily destroyed by shell. 14. The bolts which fasten the plates should be of large diameter, at least two inches; countersunk bolts, with conical heads and double nuts, have been found to answer best. 15. Soft washers should be used to protect the fastenings.

The above results, as may be observed, confirm the fact established by experiment, that the Warrior target, in proportion to its weight, offers the best protection of any target yet tried. Steel projectiles, both shot and shell, from large guns, have passed through this target; and there is no doubt that after we have arrived at the maximum thickness of iron which a vessel can be made to carry, there will be little difficulty in constructing a gun to send a projectile through its sides. A shell of 585 lb. weight, containing 24 lb. of powder, fired from the 13-inch Armstrong gun, recently penetrated the Warrior target, though the charge had been reduced so as to give the shell a velocity on striking equal to what it would have been at 2,000 yards with the ordinary service charge.

War vessels have been built, under the direction of the chief constructor of the navy, having a greater thickness of armour than that of the Warrior; such are the Minotaur and Bellerophon; and the cupolas of the Royal Sovereign, a man-of-war altered on Captain Coles' plan, have a thickness of plating, around the ports, of eleven inches.

Iron-clads have been extemporised in America during the late war, by both the Northern and Southern States, by fastening rails or chain cables along the sides of the vessels. This kind of armour, although sufficient to break up cast-iron shells, as shown in the action between the Kearsage and Alabama, off Cherbourg,

IRON PYRITES

would offer little resistance to the steel projectiles now in use with the artillery which will be brought against iron-clad vessels.

Some alterations are likely to be made in the manner of securing the plates, the bolt system being very defective. Wood screws appear to give good results, and may possibly be substituted for, or used in conjunction with, bolts.

The weight of armour which a ship can carry is, of course, bounded by certain limits; there is, however, no limit but that of expense to the armour which may be placed upon fortresses. The embrasures especially require protection, and various shields have been proposed for this purpose. Thorneycroft's bars, although rejected in this country, have been supplied to the Russian Government for the defences of Cronstadt. A shield, the invention of Captain Inglis, R.E., has been found to give very satisfactory results. It consists of planks of wrought-iron crossing each other at right angles, the front layer being 6 inches, 7 inches, and 8 inches thick, and the rear layer 5 inches thick, secured through the centres by screw bolts with elastic washers under the nuts. This shield was fired at with a 300-pounder Armstrong gun and other heavy ordnance; but, though much shaken, it was not penetrated. The conditions of weight of armour for land fortifications being essentially different to those for ships, as above stated, it appears that a shield can be made to withstand any ordnance brought to bear on it. The problem is, to effect this at the least cost.

For the questions of the velocity necessary to penetrate armour plate, and the best form and material of shot, the reader is referred to the articles GUNNERY and PROJECTILE.

Iron Pyrites. Yellow sulphide of iron. A bisulphide of iron, composed of iron 28 + sulphur 32. It is a very common and abundant ore of the metal; it has hitherto been principally employed for the production of the sulphate of iron, or of *green vitriol*; but since the attempt to create a monopoly in the sulphur trade, it has been largely used for the preparation of sulphuric acid. [PYRITES.]

Iron Ships. [IRON ARMOUR PLATE.]

Iron-clad Ships. [IRON ARMOUR PLATE.]

Ironwood. The name given to the hard wood of various trees in different countries, and more particularly to the trees of the genus *Sideroxylon*. That of Bourbon is *Cupania Sideroxylon*; those of the Dutch East Indies, *Eusideroxylon Zuergeri*, *Namia vera*, *Intsia amboinensis*, *Mimocylon ferreum*, *Stadmannia Sideroxylon*, *Sloëtia Sideroxylon* and others; that of Morocco is *Argania Sideroxylon*; that of Norfolk Island, *Noctela longifolia*; that of North America, *Ostrya virginica*. These names by no means exhaust the list of plants to which the term is applied.

Irony (Gr. *σιῶρεῖα*, from *σιῶρ*, a dissembler, as saying less than he thinks). In Rhetoric, a quality of style and of sentiment which Aristotle designates by this term is some-

IRREDUCIBLE EQUATION

what different from that which bears the same title in modern phraseology, being, in fact, only a subdivision of it. Irony, in his sense of the word, is an artful representation of qualities or things as less than they really are. Thus, among the various characters of the human mind as given by him, the *σιῶρ* is one who affectedly conceals or depreciates his own good qualities. Quintilian gives to rhetorical irony a far more general sense, terming it *diversiloquium*, or the use of expressions contrary to the thoughts of the speaker. He also distinguishes it into two species, treating it as a trope or figure of speech where the opposition of thought to language extends only to a few words; a figure of thought, where it extends to a whole passage or discourse. The Socratic irony is employed in argument when one speaker affects to take the positions of the other for granted, in order adroitly to lead him into self-contradiction or obvious absurdity. In the ordinary sense, irony is a more delicate species of sarcasm, by which praises are bestowed where it is intended to convey the opposite sense of disapprobation; or assent is notified where the real object is to express dissent.

Irradiation (Lat. *irradio*, *I shine on*, from radius, a ray). The apparent enlargement of a strongly illuminated object. Thus a platinum wire raised to incandescence appears much thicker. The impression produced by light on the retina appears to be extended, though to an extremely small distance, round the image of the object formed by the lens of the eye. The 'new moon with the old moon in her arms' is an appearance due to irradiation, as also the apparent projection beyond the planet's disc of the polar snows of Mars.

Irrational. In Arithmetic, an irrational quantity or *surd* is one whose ratio to unity is not equal to that of any two finite numbers. Irrational quantities are met with in attempting to extract the roots of numbers: thus the square root of 2 is irrational; it may be represented by the symbol $\sqrt{2}$, but it can only be approximated to by actual calculation. The term *irrational* is also applied to algebraic expressions which involve fractional indices or radical signs; and an expression of this kind is said to be *rationalised* when, by the performance of suitable algebraic operations, its irrational form is made to disappear. Thus the equation

$$\sqrt{x} + \sqrt{y} + \sqrt{z} = 0$$

by obvious processes of transposition and involution may be made to assume the rational form,

$$x^2 + y^2 + z^2 - 2yz - 2zx - 2xy = 0.$$

Irreducible Case. [CUBIC EQUATION.]

Irreducible Equation. An algebraic equation, whose coefficients are rational functions of any known quantities, is said to be *irreducible* when the function which is equated to zero is not divisible by any function of lower degree whose coefficients are likewise rational functions of known quantities.

IRREGULAR

Irregular (Lat. in, neg., and regula, a rule). In Botany, having the parts which constitute one series in a flower, the petals for example, dissimilar in size and form.

Irregular Cadence. In Music, one which does not end upon the essential chord of the mode in which a piece is composed. [CADENCE.]

Irregular Troops. Troops enlisted, paid, and officered differently from the regular army, and in general subject to different rules of discipline. There are several regiments of irregular cavalry in India; in these the men provide their own horses, arms, clothing, and subsistence. The regiments are raised by voluntary enlistment, and the men must serve twenty years before they receive any retiring allowance.

Irrigation (Lat. irrigatio). The art of spreading water over lands artificially, and by means of surface drains or channels, as contrasted with watering by manual labour. In Great Britain and in analogous climates, irrigation is confined to grass land; but in warmer climates, such as those of Italy, Spain, India, &c., irrigation is considered to be essential to the production of large crops in every kind of field or garden cultivation. When any surface is to be irrigated, the supply of water that is to be used for this purpose is conducted to the highest point of the field, and it is thence led over the surface in open gutters, so as to run very slowly, and to sink into the earth as it proceeds. In general no great surface can be irrigated at the same time, and different parts of a farm or of a field must be irrigated in succession. In countries where this practice is universal, it often happens that one source of supply is common to two or more farms, the occupiers of which have the water on alternate days; but the rights of water are subjects of frequent dispute. In the south of France, and in Italy and Spain, abundant crops cannot be produced without irrigation, which forms a necessary part of the education of the agricultural engineer. Even the potato crop and madder are irrigated in the neighbourhood of Arignon; and in Tuscany, wheat, maize, beans, turnips, and every other crop that can be sown with the drill is watered from artificial channels; while in India the cotton, sugar, and indigo crops are considered to require irrigation. The practice is as old as human civilisation; and some of the first machines we read of in history are those for raising the waters of the Nile, Tigris, and Euphrates, for irrigating the lands upon their banks. Water, in short, is to the agriculture of warm climates what manure is to the cultivator of temperate latitudes; and the efforts of the wisest rulers have been at all times directed to securing a proper supply of it. The English government has lately encouraged vast works for this purpose in its Indian possessions, and these have already yielded enormous profits. The irrigation works of the Moors of Spain may still be referred to

ISATIS

as models of that description of enterprise. The reader who may desire to study this subject thoroughly would do well to consult Baird Smith's works *On Indian Irrigation* and *On the Irrigation of the Madras Territory*; Nadault de Buffon's *Traité de l'Irrigation de l'Italie Septentrionale*, and his *Traité de l'Agriculture Hydraulique*. The article on 'Water Meadows' in the *Aide Mémoire* of the military sciences may be consulted for the bibliography of the subject. A description of the works upon the great Ganges canal would also repay the attention of anyone who might think fit to trace the progress of the art of irrigation: some of them are amongst the most gigantic hydraulic works ever executed, as for instance the Solani aqueduct, which has a clear waterway of 180 feet in width by 10 feet in depth, with a headway above the valley of the river traversed equal to about 30 feet. This work was executed by the late East India Company, which fully appreciated the importance of irrigation.

Irvingites. The name popularly given to the followers of Edward Irving, who died at Glasgow in 1834. This celebrated preacher drifted into a system of mysticism, in which the doctrine of a millennium, with the power of working miracles and speaking with tongues, bore a prominent part. After his death, this system was greatly developed by his adherents, who organised themselves into a body to which they have given the name of the 'Catholic and Apostolic Church.' The titles and gradations of their ministers are borrowed from the Hebrew hierarchy of angels, while their discipline and doctrine in some respects resemble those of the church of Rome.

Isadelphous (Gr. *isadelphos*, like a brother). In Botany, when the separate bundles of stamens in a diadelphous flower are equal or alike.

Isatimide. A crystalline yellow powder formed on passing dry ammonia into an alcoholic solution of isatin.

Isatin. The product of the oxidation of indigo by chromic acid. It occurs in beautiful rose-red crystals.

Isatis (Gr. *isidris*). A genus of *Crucifera* which yields one or two dye plants, *I. tinctoria*, the Woad, and *I. indigotica*, the Teinching of China. Woad is said to have been originally a native of South-eastern Europe, whence it has spread by means of cultivation, and become naturalised in Europe as far north as Sweden, and also in some parts of Asia. Before the use of indigo became common among European dyers, the blue colouring matter obtained from this plant was an article of great importance; but the introduction of indigo has almost entirely superseded it, and it is now only grown to a slight extent, and used chiefly by woollen dyers for mixing with indigo, in order to excite fermentation. It is generally prepared by grinding the leaves into a paste, which is then carefully fermented in heaps, and afterwards made into balls or bricks for sale. Small quantities of these balls are

ISCHIOCELE

annually imported from the Continent, amounting in 1869 to 200 cwt. The use of woad as a dye dates from very early times. Dioscorides, Pliny, and others, mention its use for dyeing wool; and Cæsar relates that the ancient Britons used it for staining their bodies—the word Britain being derived from the Celtic *brith* or *brit*, 'painted,' in reference to this custom.

I. indigotica is cultivated as a tinctorial plant in the north of China, where it is called *Trin-ching*, and takes the place of the indigo of the south. Its colouring matter is obtained by a process closely analogous to that employed in the preparation of indigo; but instead of being thoroughly inspissated, so as to form solid cakes, it is used by the Chinese dyers in a semi-liquid or pasty state. It is commonly employed for dyeing cotton cloth, to which it imparts a dark-blue colour.

Ischioccele (Gr. *ischion*, the hip, and *κῆλη*, tumour). A hernial tumour at the Foramen of the ischium.

Ischium (Gr. *ischion*). One of the bones of the fetal pelvis, and a part of the *os innominatum* in the adult.

Ischnophonia or **Ischophonia** (Gr. *ischnophonia*, from *ischos*, thin, and *phonia*, voice). Terms used by pathologists to designate a thin or small voice, loss of voice, and imperfect speech or stammering.

Ischuria (Gr. *ischia*, I retain, and *ουρα*, urine). Retention of urine.

Iserine. A variety of Titaniferous Iron, found disseminated in Iron-sand near the source of the Iser, in Silesia.

Isethionic Acid. An uncrystallisable stable isomer of sulphuronic acid; formed when solution of ethionic acid is boiled.

Isinglass (Ger. *häusenblase*, the air-bladder of the sturgeon). A very pure form of gelatine, prepared from certain parts of the entrails of several fish. The best is derived from the sturgeon, and is almost exclusively imported from Russia, twisted up in rolls or formed into cakes, which are afterwards torn into shreds or cut into fine shavings in this country. Good isinglass should be free from smell and taste, and perfectly soluble in boiling water.

Isis. One of the chief deities in Egyptian mythology, the wife of Osiris and mother of Horus. She is, however, very variously described, and invested with many different characters. By the Greeks, she was generally identified with Demeter (Ceres). Among the higher and more philosophical theologians she was made the symbol of Pantheistic divinity: see especially the remarkable passage at the end of the *Golden Ass* of Apuleius. By the people she was worshipped as the goddess of fecundity, and in her honour an annual festival was instituted which lasted seven days. The cow was sacred to her. She was represented variously, though most usually as a woman with the horns of a cow, and sometimes with the lotus on her head and the sistrum in her hand. Her priests were bound to ob-

ISLANDS

serve perpetual chastity; but when her worship passed into foreign countries, her rites became merely a cloak for sacerdotal licentiousness, which at last reached such a pitch that they were prohibited at Rome. The worship of Isis, however, was repeatedly revived, and furnished a theme for the indignant pen of Juvenal. The *Isiac Table* in the Turin Museum, which was so long supposed by the learned to represent the mysteries of Isis, 'has been judged by Champollion to be the work of an uninitiated artist little acquainted with the worship of the goddess, and probably of the age of Hadrian.' (Crenzer's *Mythol.*; Plutarch's *Treatise on Isis and Osiris*, &c. &c.; an Essay by De Montfaucon, *Hist. de l'Acad. des Inscr.* vol. xvi., which contains a summary of the Grecian learning on the subject; *Mém. de l'Acad. des Inscr.* xxxiv.; and *Quart. Rev.* July 1840.)

Isis (*Isidos* proclamos, a marine plant, like coral, according to Pliny). The name of a genus of jointed coral, in which the joints are composed of a substance resembling horn.

Islam or **Islam**. The religion of Mohammed. The body of the faithful, and the countries in which it is professed, are so termed by the Mohammedans. All those who professed the true religion and the unity of God before the arrival of Mohammed, are considered as comprised in the character and privileges of Islamism. The Mufti of Constantinople, or chief minister of religion in Turkey, bears the title of Sheikh-ul-Islam.

Island (properly eye-land, from A-Sax. eye, as in Athelney, Thorney; the word *isla* representing the Latin *insula*: Wedgwood s.v.). A tract of land encompassed with water, whether of the sea, a river, or a lake; in contradistinction to *continent* or *terra firma*.

Islands. The detached portions of land separated from each other, and from the larger masses or continents, by water spaces more or less wide and deep, are of two very distinct kinds. Some are elongated and generally parallel to continents, others are detached, rounded, or in groups and systems in open ocean. The former are called continental, and the latter pelagic. Of the continental islands of Europe, the British Islands, the islands between Italy and Spain, and those of the Grecian Archipelago are the most important. As connected with Asia and Africa, Formosa and the Japanese group, the New Zealand group, Madagascar and the islands of the Indian Archipelago, are the most characteristic; while the West Indian islands, Patagonia, and the chain of islands off the north coast of North America are illustrative examples.

Amongst pelagic or oceanic islands, may be quoted the various groups of the South Pacific Ocean, some of those in the Indian Ocean, the Canary Islands, and the Galapagos.

Most groups of islands near continents have formerly been connected with the adjacent land, while the pelagic islands are probably

ISLANDS OF THE BLESSED

related to lands now either submerged or volcanic. Many of the latter are coralline or volcanic.

Islands of the Blessed (Lat. *Insulae Beatorum*, Fortunatae Insulae; Gr. *Ἠσίοι Μακκάρ*). According to the Grecian Mythology, the Happy Islands, supposed to lie westward in the ocean, whither after death the souls of the righteous were transported. [ELYSIUM; HYPERBOREAN GARDENS.]

Ismaelians. A Mohammedan sect, who derived their name from maintaining the pretensions of Ismael, the son of Jaafar, to the rank of Imam, to the exclusion of Moussa, who was adopted by that saint. They consequently rejected the claims of Moussa and the five subsequent Imams. The Ismaelians formed a secret association, founded in the tenth century of the Christian era by Abdallah, a Persian. From them originated the famous society of the ASSASSINS. (Taylor's *History of Mohammedanism*, p. 225; *Mém. de l'Acad. des Inscrip.* vol. xvii.; 'Secret Societies of the Middle Ages,' published in the *Library of Entertaining Knowledge*, 1837.)

Isocetic Acid. A constituent of the oil expressed from Euphorbiaceous plants. In the free state it occurs in pearly scales.

Isochimeneal. [ISOTHERMAL.]

Isochromatic (Gr. *ἴσος*, equal, and *χρῶμα*, colour). Having the same colours. In certain experiments with doubly refracting crystals, the decomposed light forms a double series of coloured rings or curves of different forms, arranged in a certain order, each curve in the one series having one corresponding to it both in form and colour in the other. The two curves or lines which have the same tint are called *isochromatic*. (Herschel's 'Treatise on Light,' *Encyclopædia Metropolitana*.)

Isochronal Axes (Gr. *ἴσος*, and *χρόνος*, time). In Mechanics, axes around which, if a body be made to oscillate, the oscillations will be performed in equal times.

Isochronous. A term applied to two or more vibrations or oscillations to denote that they are performed in equal times. The term *isochronism*, as applied to a single vibrating body, denotes the property which it possesses of performing successive oscillations in equal times, notwithstanding the variation in the amplitude of those oscillations. The isochronism of the common pendulum is imperfect, but that of a cycloidal pendulum is theoretically perfect. [CYCLOID.] When the amplitudes are very small, however, the successive oscillations of a common pendulum are practically isochronous. The isochronism of a vibrating stretched string, again, is proved by the fact that the *pitch* of the note does not vary appreciably when its *intensity* diminishes.

Isoclinical Lines. Those lines which pass through places where the magnetic dip or inclination is the same.

Isodomum (Gr. *ἰσόδομος*, built alike). In Ancient Architecture, a species of walling, in which all the courses were of equal height.

ISOMEROUS

Isogenic Lines (Gr. *ἰσργένιος*, *congenial*). In Terrestrial Magnetism, the lines passing through all places on the surface of the earth at which the horizontal magnetic needle makes the same angle with the meridian, or at which the *declination* is the same. [MAGNETISM, TERRESTRIAL.]

Isolated, Insulated (from the Ital. *isola*, Lat. *insula*, an island). In Electricity, a body is said to be isolated when it is surrounded by non-conductors, or bodies to which it cannot communicate its electric virtue, except by induction. Bodies may be isolated in various ways; by suspending them by means of caoutchouc or silken cords; by placing them on a cake of gutta serena, wax, resin, or sulphur, or on a stand of glass or dry varnished wood, &c.

Isolated Point. In Geometry, a double point at which the two tangents are imaginary. It is also called a *conjugate point*. [CONJUGATE POINT AND DOUBLE POINT.]

Isomerism (Gr. *ἴσος*, and *μέρος*, part). Compounds which contain the same elements in the same ratio, and yet exhibit distinct chemical qualities, are said to be *isomeric*. The cyanic and fulminic acids are isomeric compounds of nitrogen, oxygen, and carbon. The distinctions thus arising are probably referable to the different ways in which the same elementary atoms are grouped in the compound. The ultimate elements of the hydrated cyanate of ammonia and of urea are the same, and in the same proportions, but the two substances are very distinct; the elements are differently grouped; they are carbon, hydrogen, oxygen, and nitrogen, and urea may be represented as $C_2H_4O_2N_2$, while in the cyanate they are arranged as $NH_2.C_2NO.HO$. To analogous cases in which the relative proportions of the elements in 100 parts by weight are the same, but in which the absolute number of atoms differs, the term *polymerism* has been applied. Aldehyd and acetic ether are liquids quite different in properties, but they are *polymeric*. Aldehyd is represented by $C_4H_4O_2$, and acetic ether by $C_4H_4O_4$. Two atoms of aldehyd would therefore be equivalent to one of acetic ether; but 100 parts of each liquid would yield precisely the same relative weights of carbon and hydrogen. At the same time these liquids are not mutually convertible into each other. In mineral chemistry, a similar condition presents itself in reference to the compounds known as ferro- and ferri-cyanogen. The former is Fe, C_6N_3 ; the latter has exactly double the number of atoms, $Fe_2, C_{12}N_6$. In a state of combination, their crystalline forms, colour, and chemical properties are wholly different. These facts teach us that the grouping of the atoms, apart from the composition of substances, has a material influence on their chemical and physical properties.

Isomericous (Gr. *ἰσομερής*, from *ἴσος*, and *μέρος*, a part). In Botany, equal in number. Thus an isomericous flower is one in which

ISOMETRICAL PERSPECTIVE

the different parts are equal to each other in number.

al Perspective. [PERSPECTIVA.]

Isomorphism (Gr. *isos*, and *μορφή*, form). Substances which resemble each other in their crystalline forms, but differ in their component parts, are said to be *isomorphous*. Thus the phosphate and biphosphate of soda have the same form, or are *isomorphous*, with the arseniate and binarseniate of soda; and in regard to other bases, such as potash and ammonia, each arseniate has a corresponding phosphate possessed of the same form. In these cases there is necessarily an analogy in the atomic constitution of the compounds, which are observed to possess the same number of equivalents of acid, alkali, and water of crystallisation, and differ in nothing except that the one series contains an atom of arsenic, and the other an atom of phosphorus.

Isomandra (Gr. *isos*, equal, and *δρῦς*). The genus which yields the Gutta Percha tree, *I. Gutta*, which is a large forest-tree of the Indian Archipelago, growing sixty or seventy feet high, with a trunk two or three feet in diameter, and abounding in milky juice, which is Gutta Percha. The tree belongs to the order *Sapotaceæ*. The juice has been obtained by felling the trees, and through this extravagant mode it has become extinct in Singapore, whence the produce was first obtained. The average quantity yielded by each tree is set down at 20 lbs. For the uses and properties of this substance, see the article GUTTA PERCHA.

Isoperimetric (Gr. *isos*; *περίμετρον*, circumference). A term applied to figures, rectilinear or curvilinear, having equal perimeters. An *isoperimetric problem* originally denoted one in which, of all possible isoperimetric figures, that one was required which possessed some other assigned property or properties. As an example of an isoperimetric theorem, to which the solution of such problems lead, we may cite the well-known one according to which the area of a circle is greater than that enclosed by any other isoperimetric figure. The term *isoperimetric*, however, was soon extended to a more general class of problems regarding the nature of the figure which, having certain properties in common with others, is distinguished from the latter by some maximum or minimum property.

James Bernoulli was the first who discovered the true principles on which questions of this kind depend, and the circumstances which render the ordinary methods of maxima and minima inapplicable to them. The immediate subject of his researches was the problem of the BRACHISTOCHRON [which see], or curve of quickest descent, celebrated in the early history of the calculus on account of the controversy to which it gave rise between the two brothers, James and John Bernoulli. The analysis of the former, *Analysis magni Problematis Isoperimetrical*, was published at Basle in 1701, and in the *Leipsc Act* of the same

ISOTHERMAL

year. Solutions were afterwards given by Taylor in his *Methodus Incrementorum*; by John Bernoulli in the *Memoirs of the Academy of Sciences* for 1718; and by Euler in the *Petersburg Memoirs*. Euler afterwards gave a complete and general solution of the problem in his *Methodus inveniendi Lineas curvas maximi minimive Proprietate gaudentes*, a work of which Lagrange has said that there is perhaps no other which can be of more use to those who wish to exercise themselves in the integral calculus. The method, however, which is followed in this work has been superseded by the invention of the *calculus of variations* by Lagrange; a most important branch of analysis, of which the solution of isoperimetric problems is one of the most obvious applications.

The purely geometrical treatment of isoperimetric problems has been little cultivated. One of the ablest researches of this kind was given by Steiner in Crelle's *Journal*, vol. xxiv. 1842.

Isopoda (Gr. *isos*, and *πῶς*, a foot). The name of an order of Crustaceans, comprehending those which have the legs all alike, and adapted only for locomotion and prehension.

Isopodiform. The larvæ of Saprophagous Hexapods are so called which have an oblong body, a distinct thoracic shield, and a vent provided with filaments or laminae.

Isopyre (Gr. *isos*, equal, and *πῦρ*, fire; because the effect produced upon it by the blow-pipe is like that produced on several other minerals). A silicate of alumina, peroxide of iron, and lime, found in compact masses in the granite of St. Just, near Penzance, in Cornwall. It is an amorphous mineral, resembling Obsidian, of a greyish or velvet-black colour, occasionally variegated with grey or red spots or streaks, like Bloodstone, and opaque or only slightly translucent.

Isosceles (Gr. *ἰσοσκελῆς*, from *ἰσός*, a leg). In Geometry, an isosceles triangle is one which has two equal sides. By Euclid's prop. 5, book i. the angles at the base of an isosceles triangle are also equal.

Isostemonous (Gr. *isos*, and *στήμων*, a thread or stamen). In Botany, this term, in expressing the proportion that one part bears to another, denotes that the stamens are equal in number to the petals.

Isothermal (Gr. *isos*, and *θέρμη*, heat). In Physical Geography, *isothermal lines* are those which pass through those points on the surface of the earth at which the mean annual temperature is the same. *Isoclimes* are spaces on opposite sides of the equator having the same mean temperature, and bounded by corresponding isothermal lines. On account of the irregular form and disposition of the continental masses, by which the climate of different places is greatly influenced, the isothermal curves are not parallel to the equator, excepting in the very low latitudes. According to Humboldt, the isothermal line which corresponds to the temperature of 32° Fahrenheit

passes between Ulea in Lapland, lat. 66°, and Table Bay on the coast of Labrador, lat. 54°. The isothermal line of 41° passes near Stockholm, lat. 59½°, and St. George's Bay, Newfoundland, lat. 48°. The line of 50° passes through the Netherlands, lat. 51°, and near Boston in the United States, lat. 42½°; that of 59° between Rome and Florence, lat. 48°, and Raleigh in North Carolina, lat. 36°. In all these cases we see that the isothermal lines, in passing from the western side of the continent of Europe to the eastern coast of America, deviate very considerably towards the south; the deviation in one case amounting to 11½° of latitude. In passing over the American continent, they again recede to the northward; and in California, and to the north of that peninsula, along the western side of the continent, the annual temperature is nearly the same as under similar latitudes in the west of Europe. From the western to the eastern side of the old continent, the flexure of the isothermal curves and the diminution of the mean annual temperature under the same parallels are not less conspicuous. The isothermal line of 55° passes through Nantes, lat. 47°, and Pekin, lat. 39½°. Edinburgh and Kasan (in the east of Russia) have the same latitude; but the mean annual temperature of the former is 48°, while that of the second is below 38°. For the different causes which affect the parallelism of the isothermal lines, or which produce the differences of the mean annual temperature of places under the same parallel of latitude, see CLIMATE.

Humboldt gives the name of *isotherallines* (Gr. *isos*, and *thépos*, summer) to the curves passing through those places at which the mean summer heat is the same; and of *isochiménal* (*isos*, and *χέιμωρ*, winter) to those which pass through the places at which the mean temperature of winter is the same. The isothermal and isochiménal curves deviate much more from the parallels of latitude than the isothermal. The latitudes of places having the same winter temperature sometimes differ as much as 18° or 20°. The winter of Scotland is as mild as that of Milan. The mean temperature of the winter months at Edinburgh is about 38½°; of Kasan, under the same parallel, only 2°. The winter of Pekin is as rigorous as that of Stockholm. (Humboldt's *Fragmens Asiaticques*; Murray's *Geography*, Introduction.)

ISSUANT. In Heraldry, a charge represented as issuing or coming up from another charge or bearing; also, a lion or other beast represented as rising from the bottom line of a chief.

Issue (Fr. *issue*, from the old verb *issir*—Lat. *exire*, to go out). In Law, in the most ordinary senses of the word: 1. The points in dispute in a suit at law between two parties, ascertained by the pleadings, are termed the *issues*; and are either issues in law, to be determined by the court, or in fact, to be ascertained by a jury. In each form of action

a *general issue* may be pleaded, denying the whole cause of action, as that the defendant *never was indebted* as alleged, and in cases where this is not applicable, as where the case for the defence is that a debt once existing has been paid, or that a demand has been barred by the Statute of Limitations, the appropriate issue may be raised by a special plea. [Pleadings.] A *feigned issue* was a technical mode formerly used of trying some questions, supposing an imaginary wager. In the Scottish practice of trial by jury, it is usual to put printed copies of the issues into the hands of the jurors. 2. The legitimate offspring of a man.

ISSUR. In Surgery, an artificial ulcer. It is commonly made by wounding or cutting the skin, and placing a pea upon it, which is pressed upon the part by a bandage.

Isthmian Games. One of the four great national festivals of Greece; so called from their being celebrated on the isthmus of Corinth. They were common to all the states, with the exception in this case of the Eleans. They were held near a temple of Poseidon or Neptune, and were celebrated every third year, according to some accounts, but others assign them a period of one or four years. The contests were the same as in the other sacred games [OLYMPIC GAMES]: the victors were crowned with garlands of pine leaves.

Isthmus (Gr. *isthmós*). In Geography, a narrow neck of land joining two continents, or a continent and a peninsula. Thus, the isthmus of Darien joins North and South America, and the isthmus of Suez connects Africa with Asia.

Itaconic Acid. An acid formed by the action of heat on *aconitic acid*.

Itaka Wood. The timber of *Macherium Schomburgkii*, a tree of British Guiana, a beautifully mottled wood employed for cabinet work, and also known as Tiger-wood.

Italian Architecture. [ARCHITECTURE.]

Italian Juice. The extract of Licorice prepared in Calabria. That which is prepared on the estates of the marchioness of Solazzi, and known in commerce under the name of *Solazzi juice*, being so stamped, is the most esteemed. The *Spanish juice* is prepared in Catalonia.

Italian School. When the arts began to revive after the conquest of the ancient world by the barbarians of the north, they were cultivated with especial favour in the various states of Italy where the traditions of the Roman civilisation still lingered. Thus we find that in architecture the preference for the horizontal line over the vertical line was always a characteristic of the Italian art; and in the branches connected with sculpture and painting there was, even in the mediæval times, a great tendency to revert to the types of form adopted in the Roman and the Græco-Roman school. The processes of the Byzantine painters were even retained by their Italian rivals until the commencement of the thirteenth

ITALIC SCHOOL OF PHILOSOPHY

century when Guido da Siena practised the art, and they were retained up to the time when Cimabue dared to strike out an original mode of expression. He was succeeded by Giotto, Puccio Capanna, Taddeo Gaddi, Orcagna, Starnina, Memmi di Firenze, Cavallini, Vitalis, Col Antonio del Fiore, Carlo Crivelli di Venezia, Mantegna, and Perugino, when the different sub-schools, into which Italian painting has been divided, began to be felt. The characteristics of the pure Italian school were: a simple and naive expression of the principal figures, a great harmony of parts, and a tendency to keep the subordinate figures in the background, a gradual progress in the science of foreshortening, and a careful balance of colour; the drawing was gradually raised from mediæval simplicity to the elaborate perfection of Mantegna and Perugino, who made the decisive steps which led to the formation of the schools of Michael Angelo and of Raphael, and thus established the schools of Florence and of Rome. Ghirlandajo, Lippi, Paolo Uccello, Masaccio, Signorelli, may also be cited amongst the revivers of the taste for the arts, and they were well seconded in this particular branch by Lorenzo Ghiberti, who in the bronze castings for the gates of the Baptistery of Florence merited all the praise that Michael Angelo lavished upon him. There was a constant striving after the ideal amongst the artists of the Italian school, which forms a marked contrast with the desperately realistic tendencies of the contemporary artists of the German and Flemish schools. (D'Agincourt, *Histoire de l'Art par ses Monuments*.)

Italic School of Philosophy. This school comprehends properly the Pythagorean and Eleatic systems taken together; but sometimes it is used as synonymous merely with the school of Pythagoras. Under the several heads will be found the chief features of these philosophical systems. The Italic school has been so designated because its founder, Pythagoras, is said to have taught in Italy, spreading his doctrine among the people of Tarentum, Metapontum, Heracles, Naples, &c.

Italic Types. In Printing, the elegant sloping types, the invention of which is due to Aldo Manuzio, the celebrated Venetian printer. [ALDINE EDITIONS.]

Itch (a word of doubtful origin). A disease of the skin, consisting in an eruption of minute itching vesicles, which are commonly rendered more inflamed and troublesome by scratching. They generally make their first appearance between the fingers, or about the bend of the wrist, and often spread to other parts of the body, especially where cleanliness is neglected. The itch is highly contagious, and is supposed to depend upon a minute insect burrowing in the skin; some have regarded the insect as a consequence, and not the cause, of the disease. The itch is cured by sulphur, which should be given internally, and applied externally in the form of ointment. When the smell of sulphur is objected to, ointments of white hellebore

IVORY

(*Veratrum*) and of white precipitate of mercury are frequently substituted, but they require to be cautiously used.

Itihāsas. The two great heroic poems of the Hindus, the *Ramayana* and *Maha Bharata*, are so called. They are of great antiquity; later, however, than the *Vedas*. Some, indeed, have attributed the latter poem to a period later than that of Alexander.

Itinerary (Lat. *iter*, a journey). In Literature, a work containing notices or descriptions of the places and stations to be met with in pursuing a particular line of road; as, an Itinerary from Paris to Rome: or of the principal places and stations on the great roads throughout a country; as Itinerary of France, Italy, &c. The Latin Itineraries which have been preserved to us, and of which the most important is that of Antoninus, consist merely of catalogues of stations; and are principally valuable to us because they contain the distance, in Roman miles, from one to another, and thus furnish us with assistance towards determining the actual site of each place mentioned. The *Jerusalem Itinerary* describes the route and stations between Bordeaux and Jerusalem.

Itis. This termination, added to the root of the Greek name of an organ or part of the body, implies *inflammation* of that part; as, *gastritis*, inflammation of the stomach; *pleuritis*, of the pleura; *bronchitis*, of the bronchia, &c.

Ittnerite. Named after Ittner. A rare substance, which occurs at Kaisersstuhl in the Breisgau, massive and in rhombic dodecahedrons, of a grey or bluish colour. It is a complex mineral, containing silicate of alumina, sulphate of lime, sulphide of sodium, and about ten per cent. of water.

Iulidæ. The name of a family of Myriapods, having the iulus or gally-worm as the type.

Iulus (Lat.). A genus of Myriapodous insects, characterised as follows: Antennæ with seven joints, slightly enlarged towards the end; mandibles two, thick, without palps, each divided into two by a middle joint: provided with imbricated teeth; an inferior lip formed by the confluence of two maxillæ; feet attached in double pairs to most of the joints; body long, cylindrical, capable of being contracted into a discoidal spire. The common gally-worm (*Iulus terrestris*) is an example of this genus.

Ivory (Lat. *ebur*). The peculiar modification of dentine composing the tusks of the elephant. These are chiefly or solely developed in the male. Ivory is less brittle than bone, and of a beautifully uniform texture, admitting of turning in the lathe and receiving a high polish. It consists of about 24 per cent. animal matter resembling horn, and 66 of phosphate, with a trace of carbonate of lime. The chief consumption of ivory in England is in the manufacture of handles for knives; but it is also extensively used in the manufacture of musical and mathematical instruments, chessmen, billiard-balls,

IVORY BLACK

plates for miniatures, toys, &c. Ivory articles are said to be manufactured to a greater extent, and with better success, at Dieppe, than in any other place in Europe; but the preparation of this beautiful material is much better understood by the Chinese than by any other people. No European artist has hitherto succeeded in cutting concentric balls after the manner of the Chinese; and their boxes, chessmen, and other ivory articles, are all far superior to any that are to be met with elsewhere.

The western and eastern coasts of Africa, the Cape of Good Hope, Ceylon, India, and the countries to the eastward of the straits of Malacca, are the great marts whence supplies of ivory are derived; but the most esteemed ivory comes from Africa, being of a closer texture and less liable to turn yellow than that which is brought from the East Indies. The medium weight of a tusk is about 60lbs.; and the average importation for the three years ending 1850 was 6,000 cwt., yielding a duty of 1*l.* per cwt.

Ivory Black. The mixture of charcoal and phosphate of lime obtained by burning bone is sold under this name, and, like other forms of animal charcoal, is very effective in depriving certain substances of their colour.

Ivory, Vegetable. The hard albumen of

JACK

the nuts of *Phytolophus macrocarpa*, employed in the arts, especially for turnery purposes.

Ivory's Theorem. By means of this theorem, discovered in 1809 (*Encyclopædia Britannica*, art. 'Attraction'), Ivory reduced the determination of the attraction of an ellipsoid upon an external material point to the simpler problem of finding the attraction of a confocal ellipsoid upon an internal point. To facilitate the enunciation of the theorem, it is necessary to premise the definition of *corresponding points*. Two points, one on each of two confocal ellipsoids, are said to correspond when their distances from any principal diametral plane are proportional to the axes perpendicular to that plane. This being understood, Ivory's Theorem may be thus enunciated: The components of attraction, parallel to any axis, of two confocal homogeneous ellipsoids upon equal particles situated at corresponding points, are proportional to the areas of the principal sections perpendicular to that axis.

Ivy (A.-Sax. *ifig*). The common name of the *Hedera Helix*, a well-known evergreen shrub, which climbs over buildings and up the trunks of trees, mantling them with its glossy foliage.

Jxion. [TANTALUS.]

Jxolyte. A fossil resin, found in a bed of bituminous coal at Oberhart, in Austria.

J

J. As a letter, see I.

Jabiru. The name of a Grallatorial or wading bird belonging to the genus *Mycteria*.

Jack or **Jack-tree.** The name of the *Tejaca* or *Artocarpus integrifolia*, a species of bread-fruit, found in the Indian Archipelago. The wood of this tree is called Jack-wood.

Jacamar. A genus of Scansorial birds. [GALBULA.]

Jacana. The wading birds of the genus *Parra* are so called.

Jacchus (Gr. *ἰάχῃ*, *I cry*). A genus of Platyrrhine Quadrumana, or South American monkeys, with thumbs on the hind foot only; all the digits of the fore foot having the same direction, and being armed with narrow, curved, claw-like nails. The characters of the genus are: upper middle incisors separated from and larger than the lateral ones; lower incisors elongated, narrow, and vertical, the lateral ones the longest; upper canine teeth conical, and of moderate size, but more developed than the lower ones. The species of *Jacchus* are few in number, and not very clearly defined; they are all of small size. The *Jacchus penicillatus*, remarkable for the radiated tuft of white hairs which projects in front of each ear, has bred in captivity in this country. It is a very delicate little animal, provided with a long and bushy tail, which it wraps round

its head and body when asleep or requiring warmth. Its food is of a mixed nature; but in the wild state the banana is said to be its principal and favourite nutriment.

Jacinthe (Fr.). [HYACINTH.]

Jack. Something shown, a signal. In this sense, the word is now limited in its application to the *Union Jack*, which is the distinctive badge of the United Kingdom of Great Britain and Ireland. [UNION JACK.]

JACK. A common name for the pike.

JACK. In Mechanics, an engine for raising heavy weights.

Jack is also the name given to a machine in common use for turning a spit. The common roasting jack, or worm jack, consists of a double set of wheels; a barrel, round which the chain attached to the weight or moving power is wound; a perpetual screw; and a fly, which secures a steady uniform motion. A multiplying wheel is usually added, in order that the weight may be longer in running down.

The *smoke jack* is used for the same purpose as the common jack, and is so called because it appears to be moved by the smoke of the fire. It is in fact moved by the ascending current of rarefied air, which acts on a fan properly placed in the chimney. The motion may be obtained by various contrivances. Sometimes

spiral flyers coiled about a vertical axis are employed, but more frequently a vertical wheel with oblique leaves like the sails of a windmill.

Jack or Jacques of Defence. A piece of defensive body armour worn in the fourteenth and fifteenth centuries. It appears to have been of four kinds: a quilted coat; or of leather and canvas in many folds; or formed of mail; or of small plates. It was sometimes covered with velvet and lined with silk.

Jack Sinkers. Parts of a stocking frame.

Jack Timbers. Those timbers in a bay which are intercepted by some other piece, and consequently are shorter than the remainder; thus, in a hipped roof, the rafters that are shorter than the side ones are called the *jack rafters*.

Jacks. Wooden wedges used in coal mines.

Jack-fruit or Jaca. [ARTOCARPACEÆ.]

Jackal (Arab. tschakkal, Fr. chacal). A wild species of dog, the *Canis aureus* of Linnæus, of gregarious habits. They hunt in packs, rarely attacking the larger quadrupeds, whose presence they are said to indicate to the lion by the piercing cries which they set up in chorus while scenting their tracks. They feed on the remnants of the lion's prey, on dead carcasses, and the smaller animals and poultry. The jackal interbreeds with the common dog; its period of gestation is the same, and the hybrid progeny is fertile. The wild jackal emits a highly offensive odour, which is scarcely perceptible in the domesticated animal. The *Canis aureus* is abundant in the warmer parts of India and Africa, but is not found in the New World, where it is represented by the Aguara dogs of Brazil.

Jackdaw or Daw. *Corvus Monedula* (Linn.). A common English bird, which frequents church steeples, old towers, and ruins, in flocks, where it builds its nest. The female lays five or six eggs, paler and smaller than those of the crow. The daw may be readily tamed, and taught to imitate the sounds of words. Like other species of the crow genus, they have the singular habit of stealing and hiding glittering and metallic substances.

Jacob's Ladder. In Botany, the name of the *Polemonium cervileum*, a popular garden flower.

Jacob's Ladder. In Naval affairs, a rope-ladder with wooden steps or spokes, by which the outside of the shrouds, and therefore the means of ascending the mast, is reached from the deck.

Jacob's Staff. The same as *cross-staff*. An instrument used by surveyors in measuring heights and distances where expedition and little accuracy are required.

Jacobian. A functional determinant whose line-constituents are the several first derived functions of a number of quantities in an equal number of variables. Thus the Jacobian of three ternary quantities u, v, w , is the functional determinant of the third order:

$$J = \begin{vmatrix} \frac{du}{dx} & \frac{du}{dy} & \frac{du}{dz} \\ \frac{dv}{dx} & \frac{dv}{dy} & \frac{dv}{dz} \\ \frac{dw}{dx} & \frac{dw}{dy} & \frac{dw}{dz} \end{vmatrix}$$

The Jacobian of a system of quantities is an important function which occurs frequently in the theory of elimination, and that chiefly in consequence of the property which it possesses of being reduced to zero by any system of values of the variables which simultaneously reduces to zero each of the given quantities. This same system of values, too, causes the several derived functions of the Jacobian to vanish, provided the given quantities are all of the same order. The Jacobian, it may be observed, is always a covariant of the system of quantities, since the operations

$$\frac{d}{dx}, \frac{d}{dy}, \frac{d}{dz}, \&c.$$

are contragredient to $x, y, z, \&c.$ [CONTRAGREDIENT; COVARIANT.] When the given quantities are the several first derived functions of one and the same quantic, the Jacobian coincides with the equally important function known as the *Hessian*, which of course is always a covariant of the quantic, and, together with its first derived functions, vanishes for the singular roots of the quantic. [SINGULAR ROOTS.]

The Jacobian, as its name implies, was first introduced by Jacobi; his celebrated memoir, *De Determinantibus Functionalibus*, will be found in Crelle's *Journal*, vol. xxii.

Jacobins. In Ecclesiastical History, the religious of the order of St. Dominic were so called in France, from the situation of the principal convent at Paris, near the Rue St. Jacques; also called *Frères Prêcheurs*.

Jacobins. In French History, a political club, which bore a well-known part in the first revolution. It was formed by some distinguished members of the First Assembly, particularly from Brittany, where revolutionary sentiments ran high. They took at first the name of Friends of the Revolution; but as at the end of 1789 they held their meetings in the hall of a suppressed Jacobin monastery in the Rue Saint Honoré, the name of Jacobins, at first familiarly given to them, was finally assumed by themselves. The history of the Jacobin club is, in effect, the history of the Revolution. It contained at one time more than 2,500 members, and corresponded with more than 400 affiliated societies in France. The club of the Cordeliers, formed by a small and more violent party out of the general body of Jacobins, was reunited with the parent society in June 1791, but continued to form a separate section within its limits. The Jacobin club, which had almost controlled the first assembly, was thus, during the continuance of the second, itself divided between two

JACOBITES

contending parties; although the name of Jacobins, as a political party, is commonly given to that section which opposed the Girondists or more moderate in the club no less than in the assembly. After the destruction of the latter under the Convention, the club was again exclusively governed by the more violent among its own members, until the downfall of Robespierre. After that period it became unpopular; and its members having attempted an insurrection on behalf of the subdued Terrorists, Nov. 11, 1794, the meeting was dispersed by force, and the club finally suppressed. Some writers, such as Barruel (*Hist. du Jacobinisme*), have seen in the first formation of this and similar societies the long-concocted operations of a conspiracy against legitimate government and religion throughout Europe. The Jacobins, and the other principal clubs of the Revolution, adopted all the forms of a legislative assembly. In the constitution of 1792, their legal existence was recognised. See the historians of the French Revolution, especially Carlyle, Mignet, Thiers, Michelet, Louis Blanc, for general views; also Buchez and Roux, *Histoire Parlementaire de la Rév. Française*, for the most complete series of details respecting the Jacobins and their meetings which has yet been made public.

Jacobites. In English History, that party which, after the Revolution of 1688, adhered to the dethroned monarch James I., and afterwards to his descendants. In Scotland and Ireland, where the revolution was not effected except with the assistance of arms, the Jacobite party formed one of the two great divisions of each nation; and although crushed in the latter country by conquest, they continued in the former to comprise a large proportion of the population until long after the last rebellion in 1745. But in England the revolution was effected at first with the consent of all parties; the adherents of the exiled monarch were silenced; yet, in a year or two, the Jacobite faction rose into strength, and continued to harass the government of William throughout his reign. 'It seems undeniable,' says Hallam (*Constitutional History of England*, vol. iii. p. 149), 'that the strength of the Jacobite faction sprang from the want of apparent necessity for the change of government.' Its immediate cause, however, was to be found in the refusal of a portion of the bishops and clergy to take the oaths to the new government [NONJURORS], which gave, as it were, a certain consistency and tangible ground of opposition to the friends of the dethroned monarch in general. At the same time many of William's chief advisers and officers maintained a secret correspondence with James II. at the French court, less from any attachment to his cause than with a view to secure their own interest in case of his return. After the death of James II. in France, and the accession of Anne in England, the efforts of the party languished for a time; but towards the close of her reign they revived, on the prospect of a change in the succession. We

JACQUERIE

have now undeniable proofs, from the French archives, of a fact which had been long suspected, that Bolingbroke and Oxford, with others of Anne's Tory ministers, were in treaty with the son of James II., and either really or in pretence negotiating for his return. In 1715, on the arrival of George I., broke out the unsuccessful first rebellion in Scotland; its ill conduct and failure proved a considerable check to the hopes of the English Jacobites. Bishop Atterbury, the last of their bolder intriguers and adherents, was banished in 1722, after which time it is probable that no extensive conspiracy took place on their part. In Scotland, however, the party maintained its strength, until the failure of the rebellion of 1745 put an end to its political existence. It is said that some of the party maintained a correspondence with Charles Edward, until his decease in 1787. The cardinal of York, his brother, died in 1807; and it has been said, that by his death the adhesion of the Jacobites, if any existed, was transferred to the reigning family as his next heirs. This, however, is an error; the royal house of Sardinia and other families intervening between the house of Brunswick and the crown of England, according to the strict rules of hereditary descent.

JACOBITES. In Ecclesiastical History, the Monophysite Christians of Syria are so called, from Jacob Baradai, who revived their belief and form of worship in that country and Mesopotamia, in the middle of the sixth century. Many unsuccessful attempts have been made at various times to unite them with the church of Rome. (Gieseler's *Text-book*, transl. ii. 419, iii. 414 &c.) [MONOPHYTES; EUTYCHIANS.]

Jacobus. A gold coin, so called from having been struck during the reign of James I. of England. It was worth twenty-five shillings, and weighed six pennyweights ten grains. The *Carolus*, valued at twenty-three shillings, weighed five pennyweights twenty grains.

Jacquard. A piece of mechanism applicable to silk and muslin looms for the purpose of weaving figured goods. The name is that of its inventor. (For a description of the loom, see Ure's *Dictionary of Arts and Manufactures*.)

Jacquerie. In History, the name popularly given to a revolt of the French peasantry against the nobility, which took place while King John was a prisoner in England in 1356. *Jacques Bonhomme* was a term of derision applied by the nobles to the peasants, from which the insurrection took its name. It began in the Beauvoisie, under a chief of the name of Caillot, and desolated Picardy, Artois, and Brie, where savage reprisals were executed against the nobility for their oppressions. It was suppressed after some weeks by the dauphin and Charles the Bad, king of Navarre. A similar spirit in England produced not many years afterwards the rebellion of Wat Tyler. (*Métier* i. 838; Froissart; Sismondi, *Hist. des Français*, vol. x.; Hallam's *Middle Ages*, ch. i. part ii.)

JACTITATION OF MARRIAGE

Jactitation of Marriage. In Ecclesiastical Law, a suit brought against a party who declares that he or she is married. If the other party denies the fact, then, in absence of adequate proof, the person asserting the fact is enjoined to keep silence on that head.

Jade. In Mineralogy. [NEPHRITE.]

Jaggery. A kind of coarse sugar, made from the juice of the cocoa-nut and other Palms.

Jaguar. *Felis Onca* (Linn.). The largest and most formidable feline quadruped of the New World. It is marked with large dark spots in the form of circles, with a dark spot or pupil in the centre of each; it is generally pretty numerous in the neighbourhood of the large rivers where the capibara abounds, and preys chiefly on those large Rodents.

Jalalean Era. [GELALEAN ERA.]

Jalap (so called from Xalapa in Mexico, whence it originally came). The dried root of the *Ergonium Purga*, and perhaps of some other species of *Convolvulaceæ*. This root occurs in irregular globular pieces of a dense and resinous texture: when reduced to powder it has a very peculiar and nauseous odour and taste. In doses of from five to twenty grains, jalap is a drastic purge: it is apt to gripe and nauseate.

Jalapine. The purgative principle of jalap root: it is a basic resin.

Jamaica Pepper. [ALLSPICE.]

Jambosa (from the native word Jamboe). A Myrtaceous genus of Indian trees, many of which produce edible fruit, the most esteemed being the Malay Apple, *J. malaccensis*, and the Rose Apple, *J. vulgaris*. They are sometimes included in *Eugenia*.

Jambs (Fr. jambe). In Architecture, the side or vertical pieces of any opening in a wall, which bear the piece that discharges the superincumbent weight of the building or parts of the wall above them.

James, Saint, of the Sword. A very ancient military order in Spain and Portugal. The reigning kings are grand-masters in those countries respectively. The orders in the two countries were disunited in 1288.

James's Powder. *Pulvis Jacobi*. A mixture of bone-earth, or phosphate of lime, and oxide of antimony: it is often called *fever powder*, and acts as a diaphoretic, and also on the bowels, and sometimes causes nausea or vomiting, according to the dose in which it is exhibited. It is an uncertain remedy. The *pulvis antimonalis*, or *antimonial powder* of the London *Pharmacopæia*, intended as a substitute for James's preparation, is also open to the objection of uncertain activity, dependent upon the state of oxidisation of the antimony, the protoxide of that metal being virulently active, while the peroxide is comparatively inert. The usual dose of James's powder is from one to five grains. [ANTIMONY.]

Jamesonite. A sulphantimonite of lead. It occurs in acicular crystals in Cornwall, and is also found in Siberia, Spain, Brazil, &c. Named after Professor Jameson of Edinburgh.

JANSENISTS

Janissaries or Janizaries (a corruption of the Turkish words *yeni teshari*, *new troops*). A celebrated militia of the Ottoman empire. The establishment of this corps has been usually attributed to Sultan Amurath I. in 1366; but the researches of Hammer (*History of the Ottoman Empire*, vol. i. p. 92) carry it back to Orchan, the conqueror of Nicæa (1326). This new corps was blessed by a saint of that time, Hadji Bektash by name, who cut off a sleeve of his fur mantle and gave it them as a token: whence was derived the fur cap that remained their distinguishing characteristic. This irregular infantry long remained the chief military strength of the empire, and formed a kind of warlike republic within its limits. It was supplied chiefly by the capture of young Christian slaves; and when under Mohammed IV. it began to be recruited principally from the children of the soldiers themselves, its power and importance gave signs of decay. Each regiment or oda of the Janizaries had its own soup kettle, which, in process of time, acquired a sort of prescriptive sanctity, and formed, as it were, the chief standard of the regiment; the officers and other military functionaries drawing their titles from their various supposed employments as cooks or kitchen servants. The militia of the Janizaries continued to retain a great influence in the empire itself long after it had ceased to be serviceable in the field against the armies of modern Europe. They controlled the sultans themselves, and, as it is alleged, presented a serious obstacle to all improvement, until in the year 1826 the sultan Mahmoud, on the occasion of a mutiny, dissolved the whole corps, after a bloody struggle in his capital in which 20,000 of them were said to have perished; but the number is now thought to have been exaggerated. An official publication relating to the destruction of the Janizaries was translated into French (Paris 1833). See also Walsh's *Residence at Constantinople*; Duval, *Deux Années à Const.* (1828); *Quarterly Review*, vol. xli.; *Edinburgh Review*, vol. i.; Slade's *Travels in Germany, Turkey, &c.* (1840).

Jansenists. A denomination of Roman Catholics in France, who followed the opinions of Jansen, bishop of Ypres, and formed a considerable party in the latter half of the seventeenth century. The Jansenists were Calvinistic in many of their sentiments, and in several respects approximated to the reformed opinions. They did not, however, separate themselves from the Catholic church; nor did they long survive the decree of Alexander VII., by which certain propositions extracted from their writings are condemned as heretical. The Jansenists are chiefly celebrated for their contest with the Jesuits, by whom they were at last overcome, and subjected to the enmity both of Louis XIV. and the Pope. (Leclerc, *Bibl. Univ.* vol. xiv.; Racine, *Hist. du Port Royal*; Fontaine, *Mém. pour servir à l'Hist. du P. R.*; Saint Simon, *Mémoires*; Palmer, *Essays on the Church i.* 320 &c.; Hallam, *Lit. of Europe*, vol. iii.; &c.)

JANTHINA

Janthina, more properly **Janthina** (Gr. *ἰάνθινος*, violet-coloured). A genus of Gastropodous Testaceous Molluscs, so denominated on account of the beautiful violet colour of the shell. There are but a few species of this genus known, all of which are marine, and are generally met with floating on the surface of the ocean in warm and tropical latitudes. The shell, as in all floating pelagic Testacea, is light and fragile, whence the specific name of the most common species (*Janthina fragilis*); but besides this relation of the shell to the habits and sphere of existence of the animal, each species also possesses a peculiar organ, by which it can, as it were, suspend itself to the surface of the water, and which has not hitherto been observed in any other molluscan species: this organ consists of a congeries of transparent vesicles filled with air, the parietes of the bubble-like cells being composed of a thin colourless condensed mucus, and the whole being attached to the posterior part of the foot. On account of this place of attachment, the vesicular float has been regarded as the analogue of the operculum, which otherwise is wanting; but there is an important difference connected with the float, viz. the power which the animal has, and frequently exercises, of detaching and reproducing it at will. Thus the mucous air-vesicles are cast off when the animal desires to sink: they are also made subservient to the reproductive economy of the janthina, which attaches its egg-cells to the under surface of the float, and when it is thus laden casts it off. By this means the ova are preserved in a situation where they may best receive the full influence of heat and light; and the power which the parent possesses of reproducing its float obviates the inconvenience which would otherwise result from this contribution to the well-being of its offspring. The following is the process by which the janthina has been observed to repair a mutilation purposely made in its float: The foot was advanced upon the remaining vesicles until about two-thirds of that part rose above the surface of the water; it was then expanded to the uttermost, and hrown back upon the water, like the foot of a ymnea when it begins to swim; it next became outtracted at the edges, and was formed into the shape of a hood, enclosing a globule of air which was slowly applied to the extremity of the float; there was now a vibratory movement throughout the foot, and when it was again hrown back to renew the process the globule was found enclosed in its newly made envelope. From this it results that the membrane enclosing the cells is secreted by the foot, and that there is no attachment between the float and the animal other than that arising from the adaptation and adjustment of the adjoining surfaces.

The genus *Janthina* belongs to the Pectini-anchiate order of Gastropods; the brachial cavity is capacious, and contains two continued gills. Cuvier places the genus between *Pyramidella* and *Nerita*; M. Roux con-

JASMINACEÆ

siders it to be intermediate to *Ampullaria* and *Litiopa*.

January (Lat. *Januarius*). The first month of the year. By some the name is derived from Janus, a Roman divinity; by others from *janua*, a gate. It is said that the months of January and February were inserted in the Roman year by Numa Pompilius. (Sir G. C. Lewis, *Astronomy of the Ancients*, p. 38.)

Janus (Lat.). In Mythology, a Latin deity, represented generally with two faces looking opposite ways. But the name is only another form of Dianus, as *Iana* is for *Diana*. [DIANA.] The gate of Janus at Rome was kept open in time of war and shut in time of peace. It is said that this gate was closed only six times during 800 years, viz. once in the time of Numa, at the end of the first Punic War, thrice under Augustus, and once under Nero.

Japanning. The art of covering paper, wood, or metal with a thick coat of a hard brilliant varnish: it originated in Japan, whence articles so prepared were first brought to Europe. The material, if of wood or papier mâché, is first sized, polished, and varnished; it is then coloured, or painted in various devices, and afterwards covered with a highly transparent varnish or lacquer, which is ultimately dried at a high temperature and carefully polished. The basis of this lacquer, as used by the Japanese, is said to be a drying oil derived from a species of *Stagmaria*; but the Japan varnish or lacquer in common use is a solution of asphalt in oil varnish.

Jargon. In Mineralogy, one of the varieties of *Zircon*, found in Ceylon.

Jarl. A word of Scandinavian extraction, signifying noble; applied in the early history of the northern European kingdoms to the lieutenants or governors appointed over each province. [EARL.]

Jarrah. A timber-tree of West Australia, the *Eucalyptus rostrata* of botanists. The wood is very durable, and resembles mahogany.

Jasher, or Jashar, Book of. A book to which reference is made in the Books of Joshua and Samuel. Lowth supposed that it was a collection of national songs, so called from the word with which it opened, *Jasher, he sang*. More generally the name has been taken to mean *the just*, the book being regarded as a record of the lives of righteous men. An account of the many opinions entertained of this book may be found in Horne's *Introduction to the Study of the Bible*. The most recent writer on the subject, Dr. Donaldson, in his work entitled *Jashar*, regards it as the nucleus round which the earlier Hebrew books have grown up, and as containing a pure and simple religion, which was afterwards designedly overlaid by the interpolations of a priestly caste, who had introduced the doctrine of the Fall, and an elaborate sacrificial system based upon that doctrine.

Jasminaceæ (Jasminum, one of the genera). A small natural order of Exogenous plants of the Echio alliance, with monopetal-

JASMINE

ous diandrous flowers of a regular figure. It contains few species, chiefly inhabiting the warmer parts of the world.

Jasmine (Arab. *jāsamūn*). The common Jasmine, *J. officinale*, is a hardy wall plant, with white flowers, beautiful as well as fragrant, and together with *J. grandiflorum* is principally cultivated in the south of Europe for purposes of perfumery.

Jason. In Mythology. [MEDEA.]

Jasper. A silicious mineral of various colours; sometimes spotted, banded, or variegated. It takes a fine polish, and the variety and richness of its colours render it useful in the ornamental arts.

Jateorhiza (a word coined from Gr. *ιατήρ*, a physician, and *ρίζα*, a root). A Menispermaceous genus closely allied to *Cocculus*, one species of which, *J. palmata*, formerly called *Cocculus palmatus*, furnishes the valuable medicinal root known as Calumba root. The plant is indigenous in the forests of Mozambique, whence the roots are imported.

Jatropha (a word coined from Gr. *ιαρός*, a physician, and *τροφή*, food). A Euphorbiaceous genus, to which the Mandioc plant, from which Tapioca is procured, now called *Manihot utilisima*, was once referred under the name of *Jatropha Manihot*. It has also been called *Janipha Manihot*. Some of the Indian species yield oil by crushing the seeds. The Physic Nut, *Curcas purgans*, was also once referred to this genus. [CURCAS; MANIHOT.]

Jaundice. A disease characterised by a yellow colour of the eyes and skin, deep-coloured urine, and pale evacuations from the bowels; it comes on with languor, great depression of spirits, loss of appetite, dyspeptic symptoms, vomiting, bitter taste in the mouth, and generally pain in the region of the liver. It is apparently caused either by obstruction of the duct that conveys the bile into the intestine by a gall-stone; or by a morbid and viscid state of the bile, which prevents its flowing freely; or by spasm of the gall-ducts; or by some accidental pressure upon them, such as that exercised by masses of cancerous or other malignant disease: the consequence is, that the bile, instead of passing off by the bowels, is absorbed into the blood, and becomes visible upon the skin, especially in the more delicate vessels. It is an occasional consequence of pregnancy. It has been supposed to affect infants soon after birth; but the colouration is in such instances not produced by bile. The most common cases of jaundice are probably occasioned by viscosity of bile. Pathologists in the present day recognise a form of jaundice caused by the retention in the blood of certain of the elements of bile, a form produced quite independently of any pressure on the ducts. Aperients and small doses of blue pill, with tonics, are the most essential remedies; and where it occurs in persons of sedentary habits, moderate walking and horse exercise are requisite. It is often a protracted and troublesome complaint, and then indicative of structural derangement. Jaundice

JERVIN

from gall-stones is often attended by excruciating pain and vomiting, owing to the passage of the stone. Opiates and such remedies as allay the irritability of the stomach are to be had recourse to, and the warm bath is useful. The beneficial influence of saline aperients and diluents in this disorder, has given celebrity to the waters of Cheltenham and similar mineral springs.

Javelin (Fr. *javeline*). A short spear thrown from the hand, anciently used both by horse and foot soldiers. The *pilum* of the Romans was of this description.

Jaws. In Sea language, the two sides forming the semicircular opening at the thick end of a gaff or boom. The object is to half encircle the mast, so that, the other half circle being completed with rope, the spar may at once be prevented from leaving the mast, and permitted to run up and down it when necessary.

Jay. The native bird so called is a species of the genus *Garrulus*, separated by Cuvier from the genus *Corvus* of Linnæus on account of the weaker mandibles terminating in a sudden and nearly equal curve. The tail is cuneiform, not long; and the slender feathers of the forehead can be erected like a crest. The common jay (*Corvus glandarius*, Linn.) nidicates in woods, and builds a simple nest of sticks and slender twigs; the female lays five or six eggs, of a greyish ash colour, mixed with green, and faintly spotted with brown. The young associate with the parents till the following spring, when they separate to form new pairs.

Jears. Strong tackle of blocks and stout ropes, for raising or lowering the lower yards in square-rigged ships.

Jeffersonite. In Mineralogy, a species of *Pyroxene*. It is found in New Jersey.

Jehovah. A name for the Deity in the Hebrew Scriptures. The word itself, which appears to be of Phœnician origin, was held in peculiar veneration by the Jews, who never allowed themselves to pronounce it in the reading of their sacred books, but substituted for it wherever it occurred, the term *Adonai*, or *Lord*. This practice is maintained even to this day; nor will they write the word in perfect Hebrew letters. Hence they have left the word *Jehovah* imperfectly written over the altar-piece in the synagogue in St. Helen's Place; making it to resemble that word, but in reality to signify *the Beloved*.

Jejunum (Lat. *jejunus*, empty). The second division of the small intestines; so termed because when examined after death it is generally found empty or nearly so.

Jelly. [GELATINE.]

Jerboa. [DIPS.]

Jerfalcon. The *Falco Gyrfalco* of Linnæus.

Jervin (from *Jurea*, the Spanish name of a poison obtained from white hellebore). A crystallisable alkaloid, existing along with *veratria* in the root of *veratrum album*, or white hellebore.

JESS

Jess. In Falconry, the strap by which the leash is fastened to the leg of the falcon.

Jesuates of Saint Jerome. A religious order, founded in 1363 by Giovanni Columbino, of Sienna. It was suppressed by Clement IX. in 1668.

Jesuit's Bark. [CINCHONA; PERUVIAN BARK.]

Jesuit's Drops. The compound tincture of benzoin of the *Pharmacopœia*: called also *Priar's balsam*.

Jesuit's Powder. Powdered Cinchona bark.

Jesuites de Robe. A name applied to secular persons of high rank bound to the order of Jesuits by vows of obedience, without, however, having taken the spiritual vow.

Jesuits or The Society of Jesus. The most celebrated of all the Romish religious orders; founded by Ignatius Loyola, a Spaniard, in the year 1534, when he, with Francis Xavier, and four or five other students at the university of Paris, bound themselves to undertake the conversion of unbelievers. The first principle of the society thus formed was implicit submission to the commands of the Holy See: in consideration of which their order was confirmed in 1540 by Pius III.; and from that time to the present, though with many alternations of success and reverse, the Jesuits have been one of the main bulwarks of the authority of the Roman See. The zeal which they manifested at the period immediately succeeding the Reformation, when the Dominicans and other orders which had been founded on similar principles, and had faithfully executed their mission for many ages, had degenerated into luxury and indifference, secured for them the favour of the sovereigns and other political partisans of Rome. They soon became installed in the confessionals of all the Catholic kings of Europe, and throughout the sixteenth and following century were in fact the directors of their counsels and the rulers of their subjects.

In Protestant countries they acted as the emissaries and spies of the Pope; and in England, where early in Elizabeth's reign their landing upon our shores was made a capital crime, they persevered nevertheless in keeping alive the spirit of Roman Catholicism among the harassed remnant of the old faith. They passed and repassed the channel year after year, devoting their lives, with almost a certainty of eventually suffering, to the maintenance of an illegal, and often a treasonable, correspondence with the court of Rome and the enemies of the queen's government. At the same time another division of their numerous body employed themselves with the most undaunted energy, and with an apparent success such as has never crowned the efforts of any other missionaries, in converting the heathen of Asia and America. St. Francis Xavier, the Apostle, as he is called, of the Indies, planted Christianity in Hindustan and Japan; Ricci introduced it into China. In the course of a few

JESUITS

years the number of professing Christians in these countries became very large. It should be remarked, however, that the great secret of their success seems to have been the address with which they obtained the confidence of the ruling powers. In Japan and China they became the intimate advisers of the sovereign, and frequently obtained the assistance of the civil power in the furtherance of their missionary system.

The Jesuits obtained also, throughout Roman Catholic Europe, the direction of the education of youth: they founded many schools and colleges, not only for the instruction of those who were designed for members of their own order, but for that of the upper and lower classes generally, in the education of both of which they were eminently successful.

As a religious body, the Jesuits differ from their predecessors, inasmuch as, their principle being to conform as much as possible with the manners of the age, they have never adopted the austere observances and exclusive spiritual character upon which all earlier orders had grounded their claims to notoriety. They are divided into different classes; of which only the *professed* take the religious vows of poverty, chastity, and obedience to their superior. Among the novices are frequently enrolled influential laymen, as was Louis XIV. himself in his latter years; and this is one of the means which the order has employed to extend its efficiency where it would be least liable to observation. The *professed* are of several ranks, the whole body being under the absolute control of the General, whose abode is fixed in Rome, and whose council consists of an admonitor and five assistants or councillors, who represent the five principal Catholic states—Italy, Germany, France, Spain, and Portugal. To Rome, as the central seat of the order, are sent monthly communications from the superiors of the different provinces through which its members are distributed.

The Pope has conceded to the Jesuits greater indulgence than even to laymen, exempting them from the religious observances which are enjoined on all Roman Catholics, and especially on the religious orders; and hence it is that they have been enabled to devote so great a portion of their time not only to instruction, but to many branches of learning and practice, by means of which they have insinuated themselves into the confidence and the concerns of the laity. They are remarkable also for the worldly air which when occasion serves they studiously assume—for the ease with which they dispense with all the outward appearance of their spiritual character in places where their objects seem to be more attainable by a different behaviour; and they have been reproached at all times with allowing themselves on the same principle to make use of mental reservations and other *pious frauds* in pursuance of the peculiar ends of their society. Hence, even when their influence in Europe was at its height, great distrust was manifested

towards them in many quarters. In France they were supposed to be implicated in the plots by which Henry III. fell, and the life of Henry IV. was attempted, and were indeed banished from that country by royal decree before the end of the sixteenth century: they were readmitted, however, and continued in the enjoyment of their full influence in spite of the strong opposition of the Jansenists in the reign of Louis XIV. They were banished, in the course of the eighteenth century, from France, Spain, Portugal, and other Catholic states; and in 1773 Clement XIV. issued a bull by which he decreed the total abolition of the order. The invitation, however, of Catherine II. into Russia, and the favour of the successor of Clement, restored them in some degree; and they still exist and exercise considerable influence in Italy and Spain. From Russia they are at the present moment entirely banished; nor has Portugal readmitted them since their expulsion in 1759. In France and Germany their presence appears to be connived at, though they have never formally been allowed to re-establish themselves in those countries. In England they have been allowed to found and maintain the Roman Catholic college at Stonyhurst. By the Roman Catholic Relief Bill, natural-born Jesuits are required to register themselves with the clerk of the peace in every county: foreigners must provide themselves with licenses from a secretary of state; but these provisions have never been enforced.

The history of the Order of Jesus has often been written; but with so much exaggeration, both of friends and enemies, that it is difficult to point out a fair account. The *Historia Jesuitica* of Hospinian, a Protestant, carries it down to the end of the sixteenth century. Orlandi and Sacchetti's *History of the Jesuits* was proscribed by the parlement of Paris; a fifth part was added to it by Souveny. Coudrette, one of the order, published a history of it just before its dispersion, 6 vols. 12mo. with Supplement, 1761-4. D'Alembert published an account of the destruction of the order in France, 1765. See also Georget's *Mémoires*, Paris 1817. The celebrated *Lettres Provinciales* of Pascal contain a powerful exposure of the errors of the casuistical theologians of the sixteenth and seventeenth centuries, of whom a large proportion were Jesuits. The voluminous French collection, entitled *Nouvelles Ecclésiastiques*, continued from the reign of Louis XIV. to the Revolution, was under the management of Jansenists, and contains every charge which hostility could suggest against the Jesuits. Ranke's *History of the Popes of the Sixteenth and Seventeenth Centuries* contains much valuable matter relative to that period.

According to the most recent accounts, the order numbered in 1862, 7,231 members, of whom 2,203 were French, 1,635 Italian, 740 Spanish or Portuguese, 563 German, 512 Belgian, 349 Austrian, 265 English, 126 Irish, 240 North American.

Jet. A variety of Lignite. Some jets admit

of polish, and are used for ornamental purposes. The jet found in the Lias of Whitby in Yorkshire is employed in making ornamental articles of mourning.

Jet d'Eau (Fr.). A fountain which throws up water to some height in the air. According to the theory of hydrostatics, the velocity with which water issues from an orifice is equal to that which would be acquired by a heavy body in falling through a height equal to the difference between the levels of the orifice and the fountain head; whence, if the resistance of the air and other impediments were removed, the height of the jet would be equal to that of the surface of the reservoir. Among the causes which prevent the jet from obtaining the height which theory assigns to it, the following are the principal: 1st. The resistance of the air, which is proportional nearly to the square of the velocity. 2nd. The friction against the sides of the pipe and the orifice through which the water issues. 3rd. The velocity of the particles diminishing at every instant as they ascend, the lower particles of the ascending column press against those next above them; and the pressure being by the nature of fluids communicated in all directions, the consequence is that the column is enlarged and proportionally shortened. 4th. The water at the top of the jet does not fall off instantaneously when its velocity is destroyed; it rests for a moment at the top of the column, where its weight opposes an obstacle to the particles next succeeding, and the retardation thus caused is communicated to the whole column. This last obstacle may be avoided by slightly inclining the jet from the vertical; and it is found by experience that a jet so inclined plays higher than one quite upright, though the effect is thereby rendered less pleasing. It is necessary that the diameter of the adjutage or orifice be considerably less than that of the pipe. (Desaguliers, *Experimental Philosophy*; Mariotte, *Mouvement des Eaux*.)

Jeterus. Vegetable jaundice, a disease of plants, where the system becomes affected with a general yellowness.

Jetsam. [FLOTSAM.]

Jetty (Fr. jetée). A landing place carried out from the bank of a river, or from the seashore, so that vessels may be enabled to discharge their passengers or cargo at all times of the tides. They may be either solid, so as to act as a species of breakwater, as is the case in the harbours upon the seacoast; or they may be made so as to allow the tide wave to flow uninterruptedly past them, as is the case in the various jetties upon the banks of the Thames. In hydraulic engineering, the two arms of a port are always spoken of under the name of *jetties*; they may be of wood, stone, or iron.

Jew Stone. The fossil spine of a large egg-shaped echinus.

Jew's Ear. The popular name of a cup-shaped tough but gelatinous fungus, velvety without and wrinkled within, to which botanists give the name of *Urnecia* or *Eradia*

Aurioula Juda. It was formerly employed in gables, but its virtues seem to be imaginary.

Jew's Harp. An instrument of metal, with a flexible vibratory thin metal tongue fixed to its circular base; on which tongue the breath, acting in different degrees of force, produces something like a modulated air. It is shaped thus, . The outer bars are placed between the teeth, and the central piece or tongue is set in vibration by the action of the fingers.

Jew's Pitch. *Asphaltum.* [ASPHALT.]

Jezids. A sect of religionists, long settled in the mountainous country near Mosul; said to be disciples of Yezid Ben Anisa, a Mohammedan doctor. Their religion, however, is said to be a mixture of the ancient Manichean belief of those regions with the tenets of Mohammedanism and Zendism. They appear to be on better terms with the Christians than with the neighbouring Turks, by whom they are characterised as worshippers of the devil (Arab. *Scheitan*), whose name, it is said, no threats of punishment will force them to pronounce, and whom they only mention by periphrases, as *the great sheikh*, or *he whom you know of*. They live in villages, huts, and tents, and are dreaded for their ferocity and robber-like habits. They are noticed at length in a preliminary dissertation to Sylvestre de Sacy's *Description du Pachalik de Bagdad*, 1809; said to be the work of Futher Garzoni, who was eighteen years a missionary in Kurdistan. (See the art. 'Jeziden' in Ersch and Gruber's *Encyclopædia*.)

Jib. A large triangular sail between the fore-topmast head and the jibboom in large vessels, and between the masthead and bowsprit in schooners, cutters, and other small craft. When the wind is a-beam, the jib serves to counteract the tendency of the driver to bring the ship's head towards the wind.

The effect of this sail would seem to be to lift the ship's head; yet seamen find that as the wind freshens it causes the ship, on the contrary, to plunge, and they either *ease it in* (along the boom), or haul it down. This anomalous effect may be explained as follows:—

Let x and z be the horizontal and vertical coordinates of the centre of effort, the centre of gravity of the vessel being the origin: let P be the resultant of the pressures on the sail. This may obviously be resolved into three; δ the direct effort along x , λ the lateral effort along y , and ρ the vertical effort in z . The moment to raise the bow is $x\rho - z\delta$. If $z\delta$ exceed $x\rho$, the effect is negative or tends to depress the bow. In all vessels $x > z$, also $\delta > \rho$ generally; hence the effect is not so decided as it may appear at first to be.

Let ϵ be the angle which P makes with the horizon, and ϕ be the angle between x and the horizontal projection of P ; then $\rho = P \sin \epsilon$, and $\delta = P \cos \epsilon \cos \phi$: hence the effect is

$$P (x \sin \epsilon - z \cos \epsilon \cos \phi).$$

When the wind is aft, $\phi = 0$, and $\epsilon = 90 - \pi$

(the inclination of the jib-stay to the horizon nearly); and the effect is

$$P (x \cos \kappa - z \sin \kappa),$$

which, as $\kappa = 45^\circ$, is positive or lifting.

When the wind blows fresh, the vessel being close hauled and heeling over, the stay *sags* to leeward; and the after-leech being also slacker than the foot, the resultant P may become horizontal or $\epsilon = 0$, or even negative; in which last case the effect is

$$-P (x \sin \epsilon + z \cos \epsilon \cos \phi),$$

which is altogether depressing. If now the jib be eased in, x and z are diminished. Hence, in general, the plunging effect of the jib is owing to the heeling of the ship, and to the sheet being too flat aft. The like reasoning obviously applies to staysails.

Jib Door. In Architecture, a door so constructed that it stands flush with the adjoining face of the wall on both sides, and without dressings or architraves. Thus it appears to form part of the wall, the intention of a jib door being simply to disguise the aperture.

Jibboom. On Shipboard, a movable spad running out beyond the bowsprit for the purpose of affording a base to the jib in large vessels, and to the flying jib in vessels of a smaller size from schooners downward.

Jibing. [GYBING.]

Jig. In Music. [GIGA.]

Jigger. On board Ship, a tackle having a block and a sheave at its respective ends, used in keeping the cable taut after being thrown off from the capstan, round which it has not taken more than two or three turns.

Jinjal or Gingal. A large musket used as a wall-piece in China and India.

Jobs. In Printing, cards, shop bills, reward bills, play bills, posting bills, auctioneers' catalogues, price lists, and other small things of a similar kind. Job houses seldom execute book printing to any great extent, as their materials are not calculated for it.

Joggie Piece. In Architecture, a truss post whose shoulders and sockets receive the lower ends of the struts, which are framed into them with a joggie joint.

Joggled Joints. In Architecture, the joints of stones or other materials, indented in such a way that the adjacent stones fitting into the indentations, they are prevented from being pushed away from each other by any forces perpendicular to the pressures by which they are thus held together; joggle joints gave lateral stiffness to the assemblage.

Jogues or Yugs. Eras of extraordinary length in the mythical chronology of the Hindus. They are four in number, and are called respectively Suttie, Tirtah, Dwupnar, and Collee. In character they answer closely to the Hesiodic ages in Greek mythology. [SARUS; SOTHIAIC PERIOD.]

John Bull. This well-known collective name of the English nation was first used in a satire (confidently ascribed to Arbuthnot,

JOHN DORY

though not actually sowned by him). *The History of John Bull*, usually published in Swift's works; in which the French are designated as Lewis Baboon, the Dutch as Nicholas Frog, &c.

John Dory (Fr. *dorée*, *gilt*, in reference to its yellow colour). In Ichthyology, *Zeus Faber*, the best known example of the Dory family of fishes, grouped by M. Valenciennes as the fifth great tribe of Scomberoids. In Gascony the John Dory is known by the name *Jan*, which signifies *cock*. It is possible, therefore, that the name John may be a corruption of this word, and not of the French *jaune*, *yellow*, which would be only a repetition of the epithet *dorée*.

Joinery. In Architecture, the art of framing woodwork for the finishing of houses, such as doors, sashes, shutters, cupboards, &c. The term *carpentry* is applied to the woodwork of a building which is of rough nature, and can be prepared with the axe, adze, chisel, and saw.

Joint Tenancy. In Law, where lands and tenements are granted to two or more persons to hold in fee simple, fee tail, for life, for years, or at will, without any words separating the title to their shares. Its properties are said to be unity of interest, of title, of time, and of possession; and it is subject to the right of survivorship. Joint tenancy may be severed by partition, or by the alienation of any party, but not by will. Personal chattels may be the subjects of a joint tenancy.

Joint-stock Companies. In Mercantile Law, joint-stock companies are now reducible to three classes: 1. Trading companies, incorporated by special Acts of Parliament, of which railway companies form the most important division, although companies formed for many other purposes have been incorporated by special Acts. 2. Companies established under the general Acts for regulating public companies which have been passed from time to time; the principle now generally accepted of limiting the liability of individual shareholders to the amount of their shares having been gradually introduced and worked out by successive amendments of the law. The last general Act is the Companies Act 1862, under which seven or more persons, under certain conditions, may form themselves into an incorporated company either with or without limited liability. 3. Mining companies on the cost-book system. The winding up of companies, either voluntarily by arrangement among the members, or compulsorily in case of insolvency, or in other ways failing to fulfil the conditions of their incorporation, is also provided for by Acts of Parliament. [**COMPANY**.]

Jointure. In Law, a settlement of lands and tenements made on a woman in consideration of marriage, ordinarily an estate for life, but the term is now usually applied to the more common provision of a rent charge. [**MARRIAGE, LAW OF**.]

Joists. In Architecture, the timbers of a floor to which the boards or the laths of the ceiling are nailed. They rest either upon the

JOUST

side walls, or upon girders, or sometimes upon both.

Where one tier only of joists is used, it is called a *single flooring* (fig. 1), A A A being the joists; and in this flooring the joists should not exceed sixteen feet in length, or bearing; and even when the bearing exceeds eight feet, they should have stiffening pieces to resist the action of torsion to which they are exposed; herringbone strutting is frequently employed with this object.

Fig. 1.

When two sets of joists are used, the floor is said to be a *double floor* (fig. 2), in which A A are called the *floor or bridging joists*; B B the binders; C C C the ceiling joists.

Fig. 2.

If the binding joists be framed into girders, the floor is then properly speaking a *double framed floor*, of which the sketch in the margin is the diagram (fig. 3). A is the girder; B, a binding joist; C C C are the bridging joists; and D D D are the ceiling joists; E being the floor boards. Of this floor, it is manifest that the girders are the main supports. The weight that ought to be put upon the joists of a building of course varies with the purpose for which it is intended; but in practice it is customary to calculate upon a weight of 112 lbs. per foot superficial for ordinary houses, twice that weight for bridges, and four times that weight for railway bridges.

Fig. 3.

Jolly Boat (Dan. *jolle*, Dutch *jol*, a *yawl*). A broad safe boat on board ship specially devoted to the purposes of the steward.

Journal (Ital. *giornale*, from Lat. *diurnus*, *daily*). Strictly, a record or account of daily occurrences. It is more extensively employed to signify a narrative, periodically or occasionally published, of the transactions of a society, &c.; as by ourselves in the phrase 'Journals of the Houses of Parliament,' &c. It is also used as synonymous with *magazine*, or other periodical publications of that class.

JOURNAL. The neck, or bearing part, of a shaft that works in a plummer block, upon which the shaft turns and is supported. The amount of friction depends upon the proportions of this part of the machinery, which is, therefore, kept within narrow dimensions.

Joust (Ital. *giostare*, Fr. *jouster*, *jouter*, to tilt). A term meaning in its primary sense the charge of a single horseman against a single antagonist, as distinguished from the tourney, the onset of a troop. The military games so called were very popular in the middle ages. Froissart gives many instances of the joust.

JUBA

Juba (Lat. *a mane*). The long and thick-set hairs which adorn the neck, chest, or spine of certain quadrupeds.

Jubaea. The Coquito Palm of Chili, very abundant in Central Chili, where a syrup called *Miel de Palma*, or Palm Honey, is prepared by boiling the sap to the consistency of treacle.

Jubé. The French name for a *wood screen*; this word is now very frequently employed in English works upon Architecture. Amongst the most celebrated works of this kind are, the jubés of Troyes, of Dixmude, of St. Étienne du Mont, in Paris, &c.

Jubilatio (Lat. *rejoice*). A name given to the third Sunday after Easter; because on that day divine service was commenced with Psalm lvi. 'Jubilatio Deo, omnes terræ' ('Sing to the Lord, all ye lands').

Jubilee (Lat. *jubilo, I rejoice*). The name given among the Jews to the grand sabbatical year, which according to the Levitical law was to be celebrated after every seven septenaries of years as a year of general release not only of all debts, like the common sabbatical year, but of all slaves, and of lands and possessions which had been alienated from their original owners. The later Jewish history seems, however, to furnish no evidence of the observance of this enactment. The idea that the jubilee was intended to be typical of the release and redemption of mankind under the Gospel dispensation, led Pope Boniface VIII., at the end of the thirteenth century, to proclaim a general indulgence to all Christians who should visit the tombs of the Apostles at Rome in the secular year 1300. At this period it was intended that the same celebration should take place only every hundredth year. In consequence, however, of the enormous afflux of pilgrims which this proclamation brought together, and the gain which resulted from it, Clement VI. abridged the interval to fifty years; and the solemnity then received the name of the jubilee in imitation of the Jewish custom. The second jubilee was accordingly solemnised in 1350. In 1389, Urban V. reduced the term to thirty-three years, the number of the life of our Saviour: it was raised again by Nicholas V. to fifty; and finally, in 1470, fixed by Paul II. at twenty-five; and the jubilee has ever since been solemnised every quarter of a century, beginning on Christmas-eve, when the Pope opens with pomp the great door of St. Peter's, which is closed except on that occasion.

Judaism. Attachment to the rites of the Jewish law. The Judaising spirit of many of the early Christians is noticed in several of St. Paul's Epistles (especially that to the Galatians), and continued for a long period to exercise much influence on the character of the religion. (Milman's *History of Christianity*, vol. i. 21, 451, &c.)

Judge Advocate General. The adviser of the crown in matters of military law. He is a barrister, a member of parliament, and of the privy council. The proceedings of all district, garrison, and general courts-martial are sub-

JUDICIUM DEI

mitted to the judge advocate general for approval; the latter being laid before the queen by him for confirmation. A deputy judge advocate is appointed to attend at all general courts-martial, and advise the court on points of law.

Judges (Lat. *judex*). In Jewish History, certain supreme magistrates who presided over the Israelites down to the reign of Saul. They were so called because they formed at once the civil and the military governors of the people. The dignity was retained for life, though it was not always hereditary. The history of the Book of Judges seems to show that they were chosen from the tribes which happened, for the time being, to have the preponderance.

Judgment (Lat. *judicium, Fr. jugement*). In the Fine Arts, the faculty of selecting that which is most suitable to the purpose.

JUDGMENT. In Law, the sentence pronounced by the court upon the matter contained in the record. The term *judgment*, in English legal language, is restricted to the decisions of a court of common law: those of a court of equity are denominated *decrees*. Judgments are said to be of four sorts: 1. Judgments in law (on demurrer, where the facts are confessed upon the pleadings); 2. Judgments in fact (on the verdict of a jury); 3. Judgments by confession or default, i.e. where both facts and law are admitted by the defendant; 4. Judgments on a nonsuit or retraxit, where both fact and law are admitted by the plaintiff, who thereupon withdraws his claim. Judgments are also said to be either interlocutory, on matters arising in the course of the proceeding; or final, on the merits of the case. Judgments, when obtained, must be signed by the proper officer, and entered of record, without which they are not judgments. Arrest of judgment arises from error appearing upon the face of the record; but such error must now be, generally speaking, in substantial matter of law, and not on mere matter of form. When final judgment for a debt has been obtained, it becomes in law a *judgment debt*, on which interest at 4 per cent. per annum is chargeable, under 1 & 2 Vict. c. 110.

JUDGMENT. In Logic, this term denotes the second of the three logical operations of the mind, which compares together two of the notions which are the subjects of simple apprehension, and pronounces that they agree or disagree with each other. Judgment, therefore, is either affirmative or negative; and the subjects of judgment are *propositions*, which are expressions of the agreement or disagreement of one term with another.

Judica (Lat.). The fifth Sunday after Lent was so called, because the service on that day began with the words of Psalm xliiii. 'Judica me, Domine' ('Judge me, O Lord').

Judicium Dei (Lat. *judgment of God*). The term formerly applied to all extraordinary trials of secret crimes, as those by arms, single combat, ordeals, &c.; in which it was believed that Heaven would miraculously interfere to clear the innocent and confound the guilty.

JUGA

[ORDEAL; QUESTION.] Full particulars of the ceremonies instituted on such occasions will be found in Ducange.

Juga (Lat. *yokes*). In Botany, the term applied to the ridges on the fruit of the *Umbellifera*.

Jugal Bone (Lat. *jugum*, or Gr. *ϑυγόν*, a *yoke*). The cheek bone; so called because it has a *yoke-like* articulation to the temporal bone and the bone of the upper jaw.

Jugata (Lat. *yoked*). Two heads represented upon a medal side by side, or joining each other.

Juggernaut. [VISHNU.]

Jugglers (Fr. *jongleurs*). A general denomination for persons who practise the arts of legerdemain, or who exhibit feats of uncommon strength or dexterity. The reader will find in Beckmann's *History of Inventions* a learned and curious account of the origin and history of all feats of this kind exhibited both in ancient and modern times.

Juglandaceæ (Juglans, one of the genera). A small natural order of Exogenous trees of the Quernal alliance, distributed through the temperate parts of North America and Asia. The common walnut, *Juglans regia*, is well known for its agreeable fruit, and the useful oil which it yields by pressure. The wood of *Juglans nigra* and *regia* is valuable for cabinet-makers' work and similar purposes.

Juglandin (Lat. *juglans*, a *walnut*). An extractive matter contained in the green shell of the walnut; it becomes rapidly brown by exposure to air. It is used medicinally as an alterative, and also as a black hair-dye.

Jugular Veins (Lat. *jugulum*, the *throat*). The veins which bring the blood from the head, descending upon the sides of the neck; they are divided into *external* and *internal*. By their union with the subclavian veins they form the superior *vena cava*, which terminates in the superior part of the right auricle of the heart.

Jugulars. The name under which Linnæus comprehended all those fishes which have the ventral fins anterior to the pectorals.

Jugulum (Lat. *the throat*). In Mammalogy, this term is restricted to the forepart of the neck, which intervenes between the throat (*gula*) and the chest. The *fossa jugularis* is the hollow in front of the sternum at the base of the neck.

Jugum (Lat. a *yoke*). In Botany, a pair of leaflets. Thus, leaves which consist of only one such pair are described by the term *unijugus*; if of two pairs, by *bijugus*; and if of many pairs, by *multijugus*, and so on.

Jujube. The fruit of the *Zizyphus vulgaris*; it resembles a small plum, and is occasionally used as a sweetmeat. What is sold under the name of *jujube paste* professes to be the dried jelly of this fruit, but is in fact a mixture of gum arabic and sugar slightly coloured.

Julian The commencement of a period invented to correspond with the cycles of the Julian year. It coincides with the 710th

JULIS

year before the creation of the world, according to common chronology.

Julian Calendar. The civil calendar introduced at Rome by Julius Cæsar, and used by all the Christian countries of Europe till it was reformed by Pope Gregory XIII. in 1582.

[CALENDAR.]

Julian Epoch. In Chronology, the epoch or commencement of the Julian Calendar. The first Julian year commenced with the 1st of January of the 46th year before the birth of Christ, and the 708th from the year assigned to the foundation of Rome.

Julian Period. In Chronology, a period consisting of 7980 Julian years. The number 7980 is formed by the continual multiplication of the three numbers 28, 19, and 15; that is, of the cycle of the sun, the cycle of the moon, and the cycle of indiction. The first year of the Christian era had 10 for its number in the cycle of the sun, 2 in the cycle of the moon, and 4 in the indiction. Now the only number less than 7980 which, on being divided successively by 28, 19, and 15, leaves the respective remainders 10, 2, and 4, is 4714. Hence the first year of the Christian era corresponded with the year 4714 of the Julian period; and hence also the year of our era corresponding to any other year of the period, or vice versâ, is found by the following rule:—

1. When the given year is anterior to the commencement of the era, subtract the number of the year of the Julian period from 4714, and the remainder is the year B.C.; or subtract the year B.C. from 4714, and the remainder is the corresponding year in the Julian period.

2. When the given year is after Christ, subtract 4713 from the year of the period, and the remainder is the year of the era; or add 4713 to the year in the era, and the sum is the corresponding year of the Julian period. (*Ency. Brit.* art. 'Chronology.')

Julian Year. The year adopted in the calendar of Julius Cæsar, and equal to 365 $\frac{1}{4}$ days. The Julian year exceeds the mean solar year, as determined by the best astronomical observations, by 11 minutes and 10 $\frac{3}{5}$ seconds, which amounts to a day in 129 years. In the course of a few centuries this error would become very perceptible, as the equinoxes and solstices would fall back towards the beginning of the year. When the Julian calendar was introduced by Cæsar, the vernal equinox fell on the 25th of March; at the time of the council of Nice, in 325, it fell on the 21st; and at the reformation of the calendar, in 1582, it had retrograded to the 11th. This observation enabled Pope Gregory to fix the length of the year more precisely, and correct the intercalations. [CALENDAR.]

Julis (Lat.). A genus of Labroid fishes, distinguished by the following characters: Head smooth; cheeks and gill-covers without scales; lateral line bent suddenly downwards when opposite the end of the dorsal fin. The Rainbow Wrasse (*Julis mediterranea*) has been taken on the coast of Cornwall.

JULY

July (Lat. *Julius*; so named by Mark Antony, in honour of Caius Cæsar, the dictator, whose gentile name was *Julius*). July is at present the seventh month of the year. In the earlier Latin calendar it was the fifth, and hence was termed *Quintilis*. The Dog-days are supposed to commence on the 3rd of this month.

Jumping Hare. A Rodent quadruped, the largest of the family of the Jerboas (*Dipodidae*), and the type of the genus *Helamys*, is so called. It is a native of the Cape of Good Hope, and inhabits deep burrows.

Juncaceæ (*Juncus*, one of the genera). A small obscure natural order of Endogenous plants of the Juncal alliance; in most respects resembling *Liliaceæ*, differing chiefly in their flowers being glumaceous, that is, thin, dry, and either brown or green in colour. There are, however, species intermediate between the two orders in this respect. None of the species are of any importance. The common rush is the usual type of the order. [*JUNCUS*.]

Juncaginaceæ (*Juncago*, an old synonym of one of the genera). A small natural order of Endogenous plants of the Alismal alliance, growing in ponds and marshes, with minute green flowers. They are allied to *Naiadaceæ*, differing in their hermaphrodite flowers. Some of them have a resemblance to rushes; others are floating plants; and some of them, as *Aponogeton*, are very handsome when in flower.

Junkerite. A native crystalline proto-carbonate of iron from Poullaouen in Brittany.

Juncus (Lat.). The botanical name of the Rush. It is an extensive and widely distributed genus, of which some twenty species occur in this country. The pith forms the wick of the now almost exploded *rush-lights*; and the stems are made into mats.

June (Lat. *Junius*). At present the sixth month of the year, but in the old Latin calendar the fourth. It consisted originally of twenty-six days, to which Romulus is said to have added four. Numa, it is stated, deprived it of one day; which, however, was again restored by Julius Cæsar, and it has ever since remained unaltered.

Jungermanniaceæ (*Jungermannia*, one of the genera). A small natural group of Acro-gonous or Cryptogamic plants, resembling mosses in appearance, and, like them, growing upon the bark of trees and in damp ground in shady places. They bear their seeds in cases containing spiral threads, which by their elasticity disperse the former when ripe. [*HEPATICÆ*.]

Juniper. The common name of *Juniperus*. The fruit of *Juniperus communis*, known as Juniper berries, is used in medicine as a diuretic; but is more largely employed in flavouring gin. When distilled with water, these berries yield an essential oil, upon which their peculiar flavour depends. Sandarach, a resinous substance occasionally used in varnishes, has been said to come from the Juniper, but on good authority it is now referred to *Callitris*. When powdered it is used under the

JUNTA

name of *pounce*, to prevent ink sinking into paper from which writing has been erased.

Junk (Dutch *jonk*, perhaps from Chinese *yong, the sea*). The name given to a kind of ship built by the Chinese, Japanese, and Malays. Cumbersome in shape, it is incapable of great speed; but these nations are good sailors, and venture on long ocean voyages in their junks with impunity.

JUNK. The name given by sailors to salt beef as supplied at sea, which by hard salting and long keeping becomes as hard as small pieces of old rope called *junks*, a word employed officially and perhaps allied to Lat. *juncus, a rush*.

Junk Ring. A metallic packing, confining the hemp packing of a piston, and capable of being screwed down upon it.

Junk Wads. In Artillery, these wads are made of oakum bound round with spun yarn, and are of similar diameter to the bore of the gun for which they are intended. They are used in firing hot shot, and also occasionally with bronze ordnance, to prevent indentation of the bore near the seat of the shot. In both cases they are placed between the charge and the projectile.

Junō. The Latin name of the divinity called by the Greeks *HERA* [which see]. She was the sister and consort of Jupiter, and was held to preside over marriage, and protect married women. The name Juno, Junonis, would answer to a Greek form *Zénon*, as Janus answers to the Sanscrit *Dyavan*. (Max Müller, *Lectures on Language*, second series, p. 452.)

JUNO. In Astronomy, one of the four small extra-zodiacal planets which circulate between the orbits of Mars and Jupiter. Juno was discovered by Prof. Harding, of Lilienthal (near Bremen), on September 22, 1804; Ceres and Pallas having been discovered previously. Juno shines as a star of the eighth or ninth magnitude, and is of a whitish colour without nebulousity. This planet at the time of its discovery was considered remarkable on account of the great eccentricity of its orbit, exceeding that of any other then known planet, and amounting to .2578, the semi-axis major being taken as unity. The effect of this eccentricity on the motion of the planet is such, that the half of the orbit which is bisected by the perihelion is described in about half the time in which the other half is described. The sidereal revolution is performed in 1592.66 mean solar days. The inclination of the orbit to the ecliptic is 13° 1' 20". The extreme smallness of the planet renders it impossible to determine its apparent diameter, and consequently its magnitude, with any degree of certainty.

Junta (Span. *an assembly*). A grand Spanish council of state. Besides the assembly of the states or *cortes*, there were two juntas: one which presided over commerce, the mint, and the mines; and the other forming a board for regulating the tobacco monopoly. In England the term *junta* (evidently of Spanish origin) has been used almost synonymously with cabal or faction.

JUPITER

Jupiter (Lat.). In Astronomy, one of the planets, and the largest in the system. The diameter of Jupiter is no less than 89,000 miles, or about eleven times that of the earth; consequently, his bulk is about 1,500 times greater than that of the earth. The mean distance of Jupiter from the sun is upwards of 495 millions of miles, or about $5\frac{1}{4}$ times the radius of the earth's orbit; and he performs his revolution in respect of the stars in 4,332 d. 14 h. 2 m. $8\frac{1}{2}$ s., which is nearly 12 years. The inclination of the orbit to the plane of the ecliptic was $1^{\circ} 18' 51''$ at the beginning of the present century, and undergoes a diminution of about a fourth of a second in a year. The inclination of the planet's axis to the ecliptic is but $3^{\circ} 5' 30''$, so that the planet can scarcely be said to have any seasons.

The disc of Jupiter is observed to be crossed generally in one direction by dark bands or belts. These belts are, however, by no means alike at all times; they vary in breadth and in situation on the disc (though rarely in their general direction). They have even been seen broken up, and distributed over the whole face of the planet, and as many as forty have been seen at once; but this phenomenon is rare. Branches running out from them, and subdivisions, as well as evident dark spots, like strings of clouds, are by no means uncommon; and from these, attentively watched, it is concluded that the planet revolves in the surprisingly short period of 9 h. 55 m. 50 sec. (sid. time) on its axis, to which the direction of the belts is perpendicular.

The parallelism of the belts to the equator of Jupiter, their occasional variations, and the appearances of spots seen upon them, render it extremely probable that they subsist in the atmosphere of the planet, forming tracts of comparatively clear sky, determined by currents analogous to our trade winds, but of a much more steady and decided character, as might indeed be expected from the immense velocity of its rotation. That it is the comparatively darker body of the planet which appears in the belts is evident from this—that they do not come up in all their strength to the edge of the disc, but fade gradually away before they reach it. (Herschel's 'Astronomy,' *Cabinet Cyclopædia*, p. 281.)

The radius of Jupiter being eleven times greater than that of the earth, and the rotation on the axis being 2.4 times more rapid, the space passed over by a point on the equator of the planet will be twenty-six times greater than that described by a point of the terrestrial equator in the same time. Hence the centrifugal force is about twenty-six times greater, and we might therefore conclude that its effect in impressing a flattened form on the planet will be much greater than that observed with regard to the earth. Now observation shows this to be the case. The disc of Jupiter is evidently not circular, but elliptic, being considerably flattened in the direction of its axis of rotation; and this appearance is no

JURINITE

optical illusion, but is authenticated by micrometrical measures, which assign 15 to 14 as the proportion of the equatorial and polar diameters. This far exceeds the compression of the earth, the ratio of the equatorial to the polar diameter of which is 302 to 301.

The density of Jupiter is very nearly the same as that of the sun, and about one-fourth of the mean density of the earth. The mass of the planet compared with that of the sun taken as unity, is .000943; but this is sufficient to produce a very sensible perturbation of the motions of some of the other planets. The proportion of light and heat received by Jupiter from the sun, compared with that received by the earth, is as .037 to 1.

Jupiter, through the telescope, is observed to be accompanied by four moons or satellites, which revolve about the planet nearly in the plane of its equator, exactly in the same manner as the moon revolves about the earth. Their configuration changes at every instant; they appear to oscillate on each side of the planet, and their rank or order of distance is determined by the extent of their oscillations. In coming between the sun and Jupiter, the satellites throw their shadows on the planet, and produce eclipses of the sun; and when they come to the side of the planet opposite to the sun, they are eclipsed in passing through the shadow. The beginnings and endings of these eclipses can be observed with great precision; and their observation furnishes the surest means of determining the sidereal and synodic revolutions of the satellites. The same observations also afford a means of determining terrestrial longitudes; and it was by means of them that astronomers discovered and measured the velocity of light. [PLANET AND SATELLITE]

JUPITER. In Mythology, the Latin name of the deity called by the Greeks Zeus [which see].

Jurassic Rocks. The limestones and other deposits of the Jura belonging to the middle secondary period offer the nearest analogues to the typical oolitic series of England, and thus the part of the geological sequence called by us *oolitic* (from the prevalence of a particular variety of limestone) is there designated *Jurassic*, the ooli

large part of the Alpine chain consists of rocks of the Jurassic period; and the deposits, owing to the great amount of mechanical disturbance and chemical action to which they have been subjected, offer singular varieties of condition. They include crystalline limestones and marbles, quartzites, and highly metamorphosed slates and schists. The fossiliferous portions, however, admit of comparison with those of England, the subdivisions being strongly marked, especially in the upper series. Thus, the upper Jurassic beds are limestones and clays, like the Portland rock and Kimmeridge clay. The middle and lower series are marked by less perfect subdivisions than in England.

Jurinite. A mineral from Dauphiny, containing *titanium*.

Jurisconsult (Lat. *juris consultus*, *learned or skilled in law*). A title given to a class of Roman lawyers, and commonly denoted by the abbreviation *icons*. From what we know of the jurisconsults, they appear to have been a different class from the *advocati* or *causidici*, who conducted causes, and to have confined themselves to the employment of giving *responsa* or opinions on cases put to them. (*Mém. de l'Acad. des Inscrip.* vol. xli.) From the recorded opinions of the most learned jurisconsults, the *Digest*, the great work of Justinian, was chiefly compiled. [ADVOCATE.]

Jurisprudence (from the Latin words *juris* *prudens*, *skilled in law*). The science of law. The term *civil jurisprudence* is sometimes restricted to the science of the Roman or civil law. For a complete list of works on this extensive subject, down to comparatively recent times, see Krug' *Phil. Lex.* art. 'Rechtslehre.'

Jury, Trial by. Of the origin and progress of this institution, as far as it has been very imperfectly traced by antiquarians, some account has been given in the historical review of the Common Law. (Forsyth, *History of Trial by Jury*, 1852.) When issue has been taken in fact in a civil suit [PLEADING], the cause stands ready for trial *at bar* of the court itself [LAW; COURTS, SUPERIOR], unless by the fiction of *NISI PRIUS* it is transferred to the sittings in London and Middlesex, or the assizes in the country. (A trial *at bar* is now only granted on application in some special cases.) The sheriff of the county is directed by a precept issued by the judges of assize to summon jurors to attend at the assizes. A similar process issues to summon jurors for the sittings in London or Middlesex. The plaintiff and defendant are alike entitled to have the cause tried by a *special jury*. The list of persons liable to serve as common jurors is made out by the churchwardens and overseers in each parish, and after being considered by justices at petty sessions, is copied into a book and delivered to the sheriff. In obedience to the precept for summoning jurors, the sheriff returns a panel or list of persons taken from this book, in number from 48 to 72, and the same panel now tries all issues, whether criminal or civil, at the session for which it is made out. The twelve jurors who are to try the cause are chosen by ballot out of this list. The qualification of a common juror is, to be a natural-born subject (unless on trial of an alien, in which the accused may if he pleases have a jury *de medietate lingue*, of which one half consists of aliens), to be free from attainder of an infamous crime, and to be between the ages of twenty-one and sixty. All such persons (with certain privileged exceptions) possessing 10*l.* a year in freehold or copyhold lands and tenements, or 20*l.* a year in lands held on lease for twenty-one years, or rated as householders to the poor's rate in Middlesex for 30*l.*, elsewhere 20*l.*, or occupying a house with fifteen windows, are liable to serve. In the city of London the juror must be a house-

holder or occupier within the city, and have property, real or personal, to the amount of 100*l.* All persons described in the jurors' book as esquires or of a higher degree, or as bankers or merchants, are qualified to serve on special juries. If on a trial sufficient qualified jurors are not in attendance, a *tales* may be prayed; and bystanders are called in to fill up the number. This seldom occurs but in special jury cases; and in these the *talesmen*, as they are vulgarly termed, are taken from the common jury list.

The jury being summoned, the trial proceeds; unless either party *challenge* the jurors. Challenges are either to the array or to the polls. A challenge to the array is an objection to the whole panel, and can only be on account of default or partiality of the sheriff. Challenges to the polls, i.e. to individual jurors, are said to be of four kinds; *propter honoris respectum*, *propter defectum*, *propter affectum*, and *propter delictum*. 1. Where a party is exempted by statute from serving, he may challenge himself. 2. Insufficient qualification is a ground of challenge by either party. 3. On supposed bias or partiality, as by reason of kindred. Challenges to the favour are on a mere suspicion of partiality. 4. Legal infamy is the fourth ground of challenge. In a criminal case the law of challenges is the same as in a civil one; except that the prisoner for felony has the additional privilege of making *peremptory* challenges without cause assigned to any number of jurors not exceeding twenty. Challenges for cause, if to the polls, are tried by the court; except those to the favour, which the court appoints two jurors if sworn, if not two indifferent persons, to try. Challenges to the array are tried entirely at the discretion of the court.

According to the common course of a trial *à nisi prius*, the counsel for that party on which the affirmative of the issue is thrown by the pleadings (that is, except in occasional cases, the plaintiff) *opens his case* by a statement to the jury, and then calls witnesses to prove it. He may now, since 17 & 18 Vict. c. 125, also sum up his case at the end, unless the opposite counsel says he is about to call witnesses. The counsel for the other party then replies; and if he also calls witnesses, he likewise may sum up, and the first speaker has a final reply. After the evidence is given and the case closed, the jurors are kept together to deliberate on their verdict. They must be without meat, drink, or fire, unless otherwise ordered by the judge; and as unanimity is necessary to a verdict, it was held at common law that if the jury could not agree, the judge might cause them to be carried round the circuit from town to town in a cart. In practice, it is usual, when they cannot be brought to agreement, to discharge the jury. Although the jury in ordinary language are said to be judges of the *fact* only, yet a general verdict in a civil or criminal case ordinarily decides both the facts, and whether the law as stated by the judge is immediately applicable to those facts. e.g. a verdict *guilty*

JURY, TRIAL BY

on a charge of murder implies both that the act was committed, and that it was committed under circumstances amounting to murder. The jury may, however, find under certain circumstances a *special verdict*, that is a verdict in which the facts of the case are specially stated, and it is left to the court to apply the law; or they may find a general verdict, subject to a special case as to a point of law. In cases of criminal prosecution for libel, much difference of opinion formerly prevailed as to the effect of a verdict. It was held by most lawyers that the only questions for their consideration were the fact of publication, and the truth of what is technically called the *innuendos*, viz. that the passages of the libel cited did apply to such or such facts and individuals. But by 32 Geo. III. c. 60 (passed through the influence of Mr. Fox) it was enacted that on every trial of an indictment or information for libel the jury may find a general verdict of guilty or not guilty upon the whole matter in issue, thus deciding whether the matter published amounts to a libel or no. As to the grand jury, see INDICTMENT.

Trial by jury, essentially an English institution, has only gradually and imperfectly made its way into the institutions of foreign countries; but its excellence for the purposes of criminal justice seems to be now generally admitted, whatever opinions may be entertained respecting its value in civil cases.

In Scotland, there is some question as to the antiquity of trial by jury in civil cases. But the practice, if ever it existed, became early obsolete; and it was reintroduced in 1815 by the Act 55 Geo. III. c. 42. The verdict of nine (out of twelve) jurors may now be taken after three hours' deliberation. In criminal cases, trials have taken place, immemorially, by an *assize* or jury of fifteen. The verdict is that of a majority, and may be either guilty, not guilty, or *not proven*; in which last case the party cannot be tried a second time.

In America, trial by jury in criminal cases, and in civil above twenty dollars, is established by the constitution of the United States. It is regulated for most purposes by the law of the several states: the general rule is that of unanimity.

Trial by jury in criminal cases was first established in France in 1791. The *jury of accusation*, analogous to the English grand jury, was then established, but shortly discontinued: the *jury of judgment* alone subsists. The jury decide, by a majority, on the question of guilty or not guilty, and subsequently whether there are *extenuating circumstances*. There is no trial by jury in civil cases; though in certain cases special bodies so termed may be called to assess damages, as in the case of compensation for *expropriation*.

Trial by jury exists in criminal cases in Belgium, Portugal (majority of two-thirds), Switzerland, and Italy. It was introduced into Prussia in 1849 (majority; but if seven to five, the judges decide); and into Austria in 1850.

JUSTICES OF THE PEACE

Jury-mast. In Naval affairs, a temporary mast erected in a ship in the room of one that has been carried away. Jury-masts are sometimes erected in a new ship to navigate her down a river, or to a neighbouring port, where her proper masts are prepared for her.

Jus (Lat. an *ordinance* of human law, as contrasted with *fas*, the obligation of divine law). According to Gaius, all law was divided into *jus gentium*, the law of nations, and *jus civile*, or the whole body of law peculiar to any state. Ulpian and other lawyers added a third distinction, namely *jus naturale*, or a law common to man and beasts. The civil law was comprehended in the *jus scriptum* and *jus non scriptum*, or written and unwritten law, and was divided into *public* and *private* law.

The word *jus* also had the meaning of a faculty or legal right. Thus we have the *jus connubii*, or right of intermarriage, a right strictly guarded in all ancient states; *jus quiritium*, or the state of full Roman citizenship; *jus imaginum*, the right of setting up busts or images of forefathers, answering to our right of using armorial bearings, &c. Modern law has introduced many other distinctions under the head *jus*, which our limits forbid us to notice. (See the article 'Jus,' and the other articles to which reference is therein made, in Dr. Smith's *Dictionary of Greek and Roman Antiquities*.)

Juste Milieu. [MILIEU, JUSTE.]

Justices of the Peace. In English Law, these magistrates are descended from the ancient conservators of the peace, and are appointed to their office in every county by the king's special commission under the great seal; which appoints them all, jointly and separately, to keep the peace, and any two or more of them to enquire of or determine felonies and misdemeanours. Some justices, also, are so by Act of Parliament or charter, as the mayor and other magistrates in corporate towns, &c., and certain other particular officers. Some justices are expressly nominated in the commission, so that certain business cannot be transacted without their presence; these are said to be of the *quorum*, and all the justices are now usually included in the list. The qualification of a justice is to have an estate of 100*l.* a year free of incumbrance, or a reversion after one or more lives of 300*l.* a year; but many privileged persons may act without qualification by estate. A justice intending to act under this commission sues out a writ of *dedimus potestatem* from the clerk of the crown in chancery, and takes certain usual oaths.

The duties and powers of a justice of the peace are of two kinds; ministerial and judicial. 1. He acts in the former capacity in preserving the peace; hearing charges against offenders; examining the informant and his witnesses; binding over the parties to prosecute or give evidence; and committing, or admitting to bail, according to the nature of the offence, parties who are brought before him. The stat. 11 & 12 Vict. c. 42 requires justices to take the

JUSTICES OF THE PEACE

most material part of the evidence on examinations before them in writing, to be returned to the assizes, both in charges of felony and misdemeanour. 2. An extensive jurisdiction, summary and formal, is now exercised by justices of the peace, numerous branches of judicature, both criminal and civil, having been gradually confided to their authority, either exercised by them individually, or at the petty sessions and general quarter sessions of the peace. The latter court, by 34 Edw. III., has jurisdiction over all felonies and trespasses whatever: in practice, simple larcenies and many other felonies and small misdemeanours are tried by a jury before it. But doubts having prevailed as to the extent of its authority, that authority in criminal cases was strictly defined in 1842 (5 & 6 Vict. c. 38); capital crimes, and also a variety of offences of the more serious class, being excepted from its jurisdiction. It has also by various statutes jurisdiction over several offences relating to highways and to game; it is an appellate court from many decisions of individual magistrates; and it has one large and exclusive power committed to its care by the legislature, viz. the hearing and deciding appeals from orders of magistrates relative to the imposition of the poor's rate, and to the removal of paupers from one parish to another in which they are shown to have a legal settlement. [SETTLEMENT.] Justices have, either singly or jointly, summary jurisdiction in questions of contract between certain classes of masters and servants; in small illegal takings of property, whether strictly personal, or in part connected with the freehold, not exceeding 5s. in value; and in common assaults and batteries not accompanied by an attempt to commit felony (stat. 24 & 25 Vict. c. 100) and in many other cases. The proceedings are in general on a written charge, sometimes termed a *complaint*; but in proceedings for a penalty more generally an information: on receiving which the justice grants a summons to cause the appearance of the party charged. An appeal to the quarter sessions from the conviction or order of justices is now in most cases expressly given by statute; and the court of session, on hearing the case, is said either to *affirm* or *quash* the conviction or order. The proceedings are further removable in some cases into the superior courts by certiorari, or by stating a special case.

Other summary remedies afforded by magistrates are in cases of forcible entry and detainer, and some that arise between landlord and tenant.

Justices of the peace are liable to actions at the suit of parties injured by them wilfully in the exercise of their authority. But it is provided by statute that they shall have notice of any action commenced against them, and the cause of such action, one month before the writ is sued out; and the action must be commenced within six months after the injury complained of. Persons recovering a verdict against a justice are now no longer (as formerly)

JUTE

entitled to double costs. These magistrates are also punishable criminally by indictment or information.

The police justices of London and its vicinity are stipendiary magistrates, created by Act of Parliament.

Justiciary, Chief (Low Lat. *magnus justiciarius*, or *capitalis justiciarius totius Angliæ*). An officer of high power and dignity under the Norman kings of England, who presided over all functions in the aula regia, or king's court, so long as it followed the person of the king; and was, says Blackstone, by virtue of his office, guardian of the realm in the king's absence. The formidable power of the chief justiciary was curbed to some extent by the provisions of the great charter, especially that which fixed the trial of common pleas at Westminster; and became altogether obsolete when the various branches of his jurisdiction were broken into distinct courts of judicature under Edward I. (Blackstone, *Com.* iii. 39.)

Justiciary, The High Court of, in Scotland. This court is composed of five of the Lords of Session, added to the Justice-Clerk, the president of the court. It is the supreme court of criminal justice; with the power of advocating or suspending all sentences of inferior criminal judges. It has circuit courts twice a year; and an additional circuit is now held in Glasgow during the Christmas recess of the court of session. The sinecure office of Lord Justice-General was in 1831 merged in that of the Lord President. [SESSION, COURT OF.]

Justices. In Law, a special writ empowering the sheriff of a county to hold plea of an action in his court. By means of this writ all personal and many real actions might be tried in the county courts. It is now disused.

Justification (Lat. *justificatio*, answering to the Gr. *δίκαισις*). In Theology, men are said to be justified when accounted just or righteous in the sight of God, or placed in a state of salvation. According to the eleventh article of the church of England, we are justified 'by faith, and not for our works or deservings.' The twelfth declares, that, 'although good works, which are the fruits of faith, and follow after justification, cannot put away our sins and endure the severity of God's judgment, yet are they pleasing and acceptable to God in Christ, and spring necessarily out of a true and lively faith, inasmuch that by them a lively faith may be as evidently known as a tree is discerned by the fruit.' The first of these articles is chiefly directed against the Romanist doctrine of meritorious works; the second, based on the language of St. James, that a 'man is justified by works, and not by faith only' (ii. 24), regards faith and works as inseparably connected, and is aimed principally against the doctrine of those who were termed Antinomians or Solifidians.

Justinian, Code of. [PANDECTS.]

Jute. The fibre of *Corchorus capsularis* and *C. olitorius*, much used in India for making cordage and coarse cloths.

K

K. A consonant, used in most ancient and modern languages. It is derived from the Greek *kappa*, the Hebrew *koph*. It has the same sound as C before *a, o,* and *u,* and hence it has often been pronounced superfluous. In Latin K occurs only in a few words, though it was frequently used in the same language as an abbreviation for words beginning with C; as K.T. for capite tonsus, &c. &c. In the French alphabet K is only used in words derived from foreign languages. As a numeral it was employed to express 250—

K quoque ducentos et quinquaginta docebit.

Kaaba. [CAABA.]

Kabbala. [CABALA.]

Kadi. [CADL.]

Kaimacan or **Calmacan.** A title given in the Ottoman Empire to a deputy or governor. There are generally two kaimacans, one residing at Constantinople, the other attending the grand vizier as his lieutenant.

Kainozoic. [CENOZOIC.]

Kakodyle (Gr. *κακός*, *bad*, and *ἔλη*, *matter*). A compound of hydrocarbon and arsenic, having the formula C_4H_8As . It is a clear liquid, which takes fire when dropped through the air, burning with a blue flame, and forming water, carbonic acid, and arsenious acid; the latter rises as a white smoke. *Cadet's fuming liquor*, called also *Alkarsine*, is an oxide of kakodyle — C_4H_8AsO .

Kakodylic Acid. *Alcargen*, or *cacodylic acid*. A product of the oxidation of kakodyle.

Kakoxene or **Cacoxene** (Gr. *κακός*, *bad*, and *ξίφος*, *quest*). A native phosphate of iron, occasionally associated with the native oxides. So called, probably, in consequence of the injurious effect produced by the phosphorus which it contains, upon the iron smelted from the ore with which it is found.

Kalamanka. The name of a favourite Hungarian dance.

Kale, Sea. [CRAMER.]

Kaleidophone (Gr. *καλός*, *pretty*; *ἔδος*, *form*; and *φωνή*, *sound*). An invention of Prof. Wheatstone's, in which a knob reflecting a point of light attached to a vibrating plate describes various beautiful curves corresponding with the musical notes produced by the vibrations.

Kaleidoscope (Gr. *καλός*; *ἔδος*; and *σκοπέω*, *I view*). An optical toy, which, by a particular arrangement of reflecting surfaces, presents to the eye a series of symmetrical images often remarkable for their beauty.

The kaleidoscope is formed by two plane mirrors or slips of glass, from six to ten inches in length, and from an inch to an inch and a half in breadth at the one end, though somewhat narrower at the other, joined together along the edges lengthwise, and inclined to

each other at an angle, which must be an even aliquot part (that is to say, the sixth, eighth, tenth, &c.) of four right angles. The edges of the mirrors are kept in contact by a strip of black silk glued along the back of the plates, which, if formed of glass, must be coated with black varnish or sealing wax, to prevent reflexion from their posterior surfaces. The mirrors being adjusted at the proper angle, are placed within a tin tube, where they are kept in their proper position by pieces of cork or wood wedged in between them and the tube. One end of the tube has a small circular aperture in its centre, to which the eye is applied; in the other end two plane glasses are fixed parallel to each other, and perpendicular to the axis of the tube, and about an eighth of an inch apart. Between these glasses, which form a cell, the objects which produce the images are placed. Those which answer the purpose best are small fragments of coloured glass, beads, or other coloured diaphanous matters, of such a size that when the tube is turned round they move freely within the cell and assume new positions. In order that the eye may not be disturbed by objects without the tube, the outer glass should be slightly ground, but the inner must be perfectly transparent.

On applying the eye to the aperture of the tube, the objects within the cell at the other end are seen multiplied by repeated reflections from the two mirrors, and a succession of symmetrical images presented, all arranged round a centre, and combined into a perfect whole. As the objects are placed loosely in the cell, every motion of the tube changes their relative positions, and produces an entirely new image; and it is this endless variety of new combinations which creates the pleasing effect.

Kalends. [CALENDS.]

Kali. An Arabic word, signifying the ashes left after the combustion of vegetable substances; hence the word *alkali*. Potassa is frequently termed *kali*, and potassium *kalium*, by the German chemists; hence K is used as the symbol for potassium.

Kalmia (from Kalm, a traveller in North America). A genus of beautiful North American Ericaceous plants, with a monopetalous corolla, which confines ten stamens by their anthers in the same number of niches in its sides. The flowers are white or pink, and the leaves evergreen; but the plants are noxious, and *K. angustifolia* has received the name of Lambkill. The Canadian partridge is said to become poisonous as human food after feeding on the *Kalmia*.

Kalyptolite. [CALYPTOLITE.]

Kami. A Japanese title belonging primarily to the celestial gods who formed their first mythical dynasty, then extended to the terrestrial gods

of the second dynasty, and then to the long line of spiritual princes who are still represented by the *micado*. [TYCOON.] In addition to this, every patriot, or anyone distinguished for saintliness or miraculous powers, may after death be deified as a *kami*, so that the number of these demigods is indefinite. Some of these spirits preside specially over the elements and powers of nature. The worship of these demigods is called *Kami-no-mitsi*, or the Way of the Kami. (Bishop of Victoria's *Ten Weeks in Japan*, p. 44; Klaproth, *Annals of Japan*, 1834.)

Kamichi. The name of a Rasorial or Gallinaceous bird, remarkable for having its wings armed with two strong spurs, and its head with a long, slender, cylindrical and nearly straight horn. [PATAMENEA.]

Kammererite. A hydrated silicate of alumina and magnesia, often accompanying chromite of iron. Named after Kammerer, the mineralogist.

Kamptulicon. A name given to a new variety of floor covering, composed of Indian rubber, gutta percha, and cork. Equal quantities of the two former substances, having been first liquefied in naphtha or some other proper solvent, are mixed with cork which has been ground into a fine dust. This mixture, while warm and soft, is flattened out, by being passed under smooth heavy rollers, into sheets ten or twelve yards long, varying in width from one to two yards, and from one-eighth of an inch to one inch in thickness. The sheets thus prepared are allowed to lie flat until sufficiently set or hardened, when they are rolled up as fit for use. Patterns are printed on the material thus prepared, in the same way in which floor cloth is stamped by blocks.

The advantages of kamptulicon over ordinary floor cloth consist in its warmth, softness, and elasticity, and if the whole floor is covered it is perhaps more durable; but on the other hand it is easily torn, and when once laid upon a floor it cannot be removed without considerable damage.

Kampylite (Gr. *καμπύλος*, *curved*; from its barrel-shaped crystals). A variety of Mimetite which is found crystallised, of colours varying from yellowish to brown and brownish-red, at Drygill in Cumberland; also at Badenweiler and Johannegeorgenstadt in Saxony.

Kamsin. A hot dry southerly wind, common in Egypt and the deserts of Africa. It blows sometimes for fifty days together.

Kanete. Native arsenical manganese, named after Sir R. J. Kane, by whom it was first noticed.

Kangaroo. The native name of a large indigenous quadruped of New Holland; it belongs to a genus characterised by a strictly herbivorous modification of the marsupial type of the dental organs, and by a remarkably long and strong tail and hind legs. [MACROFUS and MARSUPIALIA.]

Kantian Philosophy (known also by the name of the Critical Philosophy). A system

of philosophy, which owes its existence to Immanuel Kant, professor of logic and metaphysics in the university of Königsberg in the latter half of the eighteenth century. The promulgation of Kant's doctrines forms a very marked era in the history of philosophy.

At the time when Kant commenced his metaphysical labours, the philosophical world was divided between the sensualism of the French followers of Locke on the one hand, and the dogmatic rationalism of the disciples of Wolf and Leibnitz on the other. The former, by a species of analytical legerdemain, resolved all our mental powers into modifications of sense; while the latter, in an equally indiscriminating spirit, though with far more laudable intentions, sought to construct a system of real truth out of the abstract conceptions of the understanding. Against both of these schools Kant declared open warfare. Withdrawing himself from all ontological speculation, he sought, by a stricter analysis of our intellectual powers, to ascertain the possibility and to determine the limits of human knowledge. He divides the speculative part of our nature into three great provinces—sense, understanding, and reason. Our perception of the outward world is representative merely: of things as they are in themselves it affords us no notice. In order to render human experience possible, two ground-forms, under which all sensible things are contemplated, are assumed—time and space. To these he assigns a strictly subjective reality. The truth of the fundamental axioms of geometry rests on the necessity and universality of our intuitions of space in its three dimensions—intuitions which are not derived from any one of our senses, or from any combinations of them, but lie at the ground and are the condition of all sensible human experience. The understanding, or the faculty which combines and classifies the materials yielded by sense, Kant subjects to a similar analysis. All its operations are generalised into four fundamental modes or forms of conception; which, after the example of Aristotle, he names *categories*. [CATEGORY.] These are four in number: 1. Quantity, including unity, multitude, totality; 2. Quality, divided into reality, negation, and limitation; 3. Relation, viz. substance and accident, cause and effect, action and reaction; and 4. Modality, also subdivided into possibility, existence, and necessity. These form, as it were, the moulds in which the rude material of the senses is shaped into conceptions, and becomes knowledge properly so called. The categories in themselves are the subject-matter of logic, which is thus far a pure science, determinable a priori. The third and highest faculty, the reason, consists in the power of forming ideas—pure forms of intelligence, to which the sensible world has no adequate correspondents. Out of these ideas no science can be formed; they are to be regarded as regulative only, not as constitutive. The existence of God, immortality, freedom, are the objects after which the reason is

KAOLIN

perpetually striving, but concerning which it can decide nothing either one way or the other. Thus far Kant's system may be regarded as one of pure scepticism. The deficiencies of our speculative reason he conceives to be supplied by the moral faculty, to which he has given the name of *practical reason*, the object of which is to determine, not what is, but what ought to be. As the former determines the form of our knowledge, so the latter prescribes the form of our action. Obligation is not a mere feeling; it is a pure form under which the reason is compelled to regard human conduct. The personality of man, which lies at the ground of speculative knowledge, becomes in relation to action freedom of the will. It is in our moral nature that we must seek for the only valid foundation of the belief in God, the immortality of the soul, and a future state in which the demands of the practical reason shall be realised. (*Kant's Philosophical Works; Kritik der Reinen Vernunft; Kritik der Praktischen Vernunft; Masson's Recent British Philosophy; &c.*)

Kaolin. The Chinese name for *porcelain clay*. A large tract of this useful substance occurs near St. Austell in Cornwall, whence our potteries and porcelain manufactories are copiously supplied. The kaolin of Cornwall, and probably of other countries, is derived from the decomposition of the Felspar of granitic rocks.

Kapnite (Gr. *καπνός*, *smoke*). A variety of Calamine containing more than 15 per cent. of protoxide of iron, and found at Altenberg, near Aix-la-Chapelle.

Kara. A Tartar word, signifying *black*, used in many of the Eastern languages as a prefix to geographical names; as Karamania, the country of the black people. It has also been employed in the same capacity to signify *tributary*; as kara kalpacks, *tributary kalpacks*.

Karaites. [CARAITES.]

Karelinite. An oxysulphide of bismuth found in lumps of a lead-grey colour at the Sawodinsk mine in the Altai, accompanied by Telluric Silver. Named after M. Karelin.

Karmathians or **Karmatians.** A Mohammedan sect which arose in Irak during the ninth century of the Christian era. It derived its name from Karmata, its founder, a poor labourer, who assumed the rank of a prophet. They maintained bloody wars with the caliphs for nearly a century. (Taylor, *History of Mohammedanism*, p. 223; *Secret Societies of the Middle Ages*, Lib. Ent. Kn. 1837.)

Karpholite. [CARPHOLITE.]

Karphosiderite or **Carphosiderite** (Gr. *καρπός*, a chip or stalk, and *σίδηρος*, iron). A straw-coloured phosphate of iron from Labrador.

Karstenite. A mineralogical synonym of *Anhydrite*, or anhydrous sulphate of lime, after the German chemist, Karsten.

Kat. The native name of the Arabian *Catha edulis*, from which is prepared a beverage having effects similar to those of tea. Recent

KEEL HAULING

investigations, however, seem to show that its stimulating powers are not owing to the presence of theine, none having been detected in it.

Kathetometer or **Cathetometer.** An instrument for measuring differences in height, as, for instance, between two liquid columns in equilibrium. It usually consists of a small telescope, sliding vertically upon an upright scale. The telescope is furnished with cross-wires, and the point of intersection of the latter being brought to coincide with the apex of one of the columns of liquid, the position of the telescope upon the scale is read off. The telescope is then directed to the other liquid column, and the point of intersection of the wires being again brought to coincide with the apex of the column, a second reading is made. The difference between the two readings expresses the difference in vertical height between the two columns.

Kava or **Kawa.** Vernacular names for the *Ava, Macropiper methysticum*, a kind of pepper, with narcotic stimulant properties; it is chewed by the Polynesians much in the same way as the Betel Pepper.

Keckling (akin to the German *kugeln*, to roll; Dan. *kekki*). A Sea term denoting the act of encircling a cable or hawser with old rope or small chain to prevent it chafing at the hawsehole as the ship rides at anchor, or to avoid the dangerous rubbing of ice or sunken rocks.

Kedge, Kedge Anchor, Kedger (Dan. *keddsch*). A small anchor borne by large ships, and employed in shallow water to keep the ship's bow clear of the main anchor. It is also employed in moving from one mooring to another; a boat conveys the kedge, and drops it at the length of the cable or point desired, when the vessel is hauled up to it.

Keel (Icelandic, *kiolr*; Dutch, *kiel*). The principal piece of timber in a ship, first laid on the blocks in building. If we compare the body of a ship to the human skeleton, the keel seems to resemble the backbone, and the timbers the ribs. It is generally composed of several thick pieces of wood placed lengthways, which after being scarfed together are bolted and clenched through the floor timbers. From the keel rise at its extremities the stem and stern post. Serious damage to the keel involves the destruction of the ship; great care is therefore taken to protect it, by fastening, somewhat loosely, below it a *false keel*, which, if the vessel takes the ground, will probably come off and leave the true keel unharmed. The word seems originally to have signified an entire ship; for we read that the Saxons invaded England in caels (or keels), and in early times a fleet was described as so many keels. This signification partly lives in *keelage*, which is a duty levied on vessels entering certain ports.

KEEL. In Botany, a name applied in a figurative sense to the two lowest petals of a Papilionaceous corolla, which, together, have some resemblance to the keel of a boat.

Keel Hauling. An obsolete punishment practised chiefly in the Dutch navy, by which

KEELING

the culprits were let down on one side of the ship, and after passing under the keel were *hauled* up on the other. This punishment was formerly not altogether unknown in the British navy; but it is now never resorted to.

Keeling. A name for the common cod (*Morrhua vulgaris*, Cuv.). [МОРЖУГА and ГАНУС.]

Keelson. In Shipbuilding, an inner keel passing throughout the vessel's length parallel to the keel; but above the floor-timbers, through which it is bolted to the keel. It adds greatly, or rather is indispensable, to the stability of a wooden ship. The heels of the masts rest upon the keelson. *Sister keelsons* are smaller keelsons situated on each side of the keelson at a short distance for the purpose of consolidating the floor-timbers, crosspieces, and futtocks. Like the keel, the keelsons are composed of several pieces of timber scarfed together and secured by dowels or coaks. [KEEL.]

Keep (A.-Sax. *kepan*). A word denoting the stronghold of a castle, to which in cases of emergency the besieged inmates retreated, and there made their last efforts of defence. [DORR.]

Keeper of the Great Seal, Lord, or Lord Keeper. An officer of high dignity in the English constitution, whose office is created by the delivery of the king's great seal into his custody. He is prolocutor or speaker of the House of Lords by prescription. By 6 Eliz. c. 18, the offices of lord chancellor and lord keeper are declared to be of exactly the same authority; and when there is no chancellor, the great seal is ordinarily put in commission. [CHANCELLOR; SEAL.] (Bl. Com. iii. 47.) The keeper of the privy seal is styled Lord Privy Seal.

Keeper of a Magnet. [MAGNET.]

Keeping. In Painting, the management of the lights, shadows, colours, and aerial tints in such subordination to each other that each object may seem to stand rightly in the place which the linear perspective has assigned to it. Objects in the nearer parts or foreground of a picture will necessarily receive the strongest lights and shadows; and as more air is interposed in nature between the eye and the objects as they become more distant, so in the representations of them the colours must be less brilliant as they recede from the eye towards the distance wherein they are lost. This word must not be confounded with the term *effect*, though effect is doubtless the result of keeping in a picture, that word being more peculiarly applicable to the sensation produced by the combination of accidental circumstances in the disposition of light and shade.

Kellhaute or Kellhaulite. [YTTRITANITE.]

Kelloways Rock. A calcareous bed at the base of the upper oolites of England, occupying a position between the Cornbrash and the Oxford clay. It is a thin bed, and of little importance, except as separating the upper from the middle oolites. It is purely local.

KEPLER'S LAWS

Kelp. A common term for seaweed or *vraic*, which consists of different species of *Fuci* and *Laminaria*. In a strict sense, the term *kelp* is confined to the produce of seaweed when burnt, which consists of alkaline ashes used as a manure. For this purpose it is sought after by farmers on the sea coast, and especially by those who have dry soils, the salt contained in the kelp being an absorbent of moisture. It has also acquired much importance as a source of iodine.

Kelpies. In Scotch Mythology, certain supernatural beings, like Boggles and Brownies.

Kennel (Fr. *chenil*, Ital. *canilo*, from Lat. *canis*, a dog). A word denoting literally the house in which a pack of hounds is lodged, but used metaphorically for the pack itself. It signifies also the spot to which the fox after his nocturnal depredations retires about the dawn of day. Hence, on being found by the hounds in drawing cover, he is said to be *unkennelled*.

Kengottite. A mineral bearing some resemblance to Miargyrite, but containing a larger amount of silver. It is found in irregular groups of crystals, varying in colour from iron-black to lead-grey, at Felsőbanya in Hungary. Named after Professor Kengott.

Kentish Rag. A tough calcareous stone used extensively for building, and remarkably durable. It is developed at Hythe and near Maidstone in Kent, and belongs to the lowest part of the cretaceous group of England, corresponding with the Atherfield beds of the lowest part of the lower greensand of the Isle of Wight. It is very local, as a valuable building stone, even where the other beds of the lower greensand are well shown. The lower Neocomian beds of France and Switzerland, and the lower Quader of Saxony, are probably of the same age, and the latter contains building stone also. The Kentish rag is brought to London, and carried to some distance for special purposes, where durability is required.

Kepler's Laws. In Astronomy, the laws of the planetary motions, first discovered and demonstrated by Kepler. They form the basis of the whole theory of gravitation and physical astronomy, and are three in number: 1. That the planets describe ellipses, each of which has one of its foci in the same point, namely the centre of the sun. 2. That every planet moves so that the line drawn from it to the sun describes about the sun equal areas in equal times. 3. That the squares of the times of the revolutions of the planets are as the cubes of their mean distances from the sun. These three laws or general facts were discovered by Kepler from a comparison of astronomical observations; and though it was by means of them that Newton established the more general law of attraction inversely as the square of the distance, they are themselves direct consequences of that hypothesis. The first law, that of the elliptic motion of the planets, was announced by Kepler in his famous work, *Physica Cælestis tradita Commentariis de Motibus Stellæ Martis*, 1609. Kepler having com-

KEPLER'S PROBLEM

puted from the observations of Tycho Brahe the distances of Mars from the sun at different points of his orbit, found that the orbit was not circular, as had always been supposed by astronomers till then, but elliptical; and that the sun occupies one of the foci of the ellipse. He afterwards discovered the same thing to be true of the earth's orbit; and thence extended it by analogy to all the other planets. Newton demonstrated in the *Principia* that if a body projected in space is acted upon by a central force varying inversely as the square of the distance, the body will necessarily describe one of the three conic sections; but whether the orbit will be an ellipse, an hyperbola, or a parabola, depends on the intensity of the force with which it is projected.

Kepler was led to the discovery of his second law by a comparison of the sectors formed by two contiguous radii vectores and the angles included between them. The data which he assumed were not rigorously exact; but Newton afterwards demonstrated from the theory of dynamics that the fact is necessarily true of all motions regulated by a central force, whatever the law of that force may be.

The history of the discovery of the third law is remarkable. Kepler had long been persuaded that some numerical relation must exist between the periodic times of the planets and their distances from the sun. In order to discover this relation he tried successively many hypotheses, each of which involved a mass of tedious calculation. He began by comparing the intervals between the planetary orbits with the five regular solids; and having failed in this speculation, as well as in various others, he at length thought of comparing the different roots and powers of the periods and distances. After many attempts and failures, he at last perceived the analogy of which he had been so long in search.

— sera quidem repperit inertem,
Repperit tamen et longo post tempore venit,

he exclaims; and in the fulness of his delight he has recorded the year and day on which the discovery was made. It was the 8th of May, 1618; and, as Professor Playfair has remarked, 'perhaps philosophers will agree that there are few days in the scientific history of the world which deserve so well to be remembered.' (Dissertation iv. *Encyclopædia Britannica*.)

Kepler's Problem. The discovery made by Kepler, that the planetary orbits are ellipses having the sun in the focus which is common to each ellipse, and that the line which joins the centres of the sun and a planet passes over equal areas in equal times, made it necessary to solve a problem which transcended the geometry of his age: Supposing the semi-transverse axis of a planet's orbit to be represented by 1, and the eccentricity by e ; also the mean anomaly at any given instant of time by s , and the eccentric anomaly by x , both being reckoned from the perihelion, Kepler found the relation between the angles x and s to be expressed by the equation $s = x - e \sin x$.

KERMES

When x is given, s is easily found from the trigonometrical tables; but there is no direct way, unless by infinite series, of finding x when s is given, which is the case that occurs in astronomy. The determination of x in terms of s constitutes what is called Kepler's Problem. Solutions of this important problem are to be found in most works on astronomy. They are generally tentative, depending on a combination of geometrical and trigonometrical principles; but two very elegant ones, purely analytical, are given by Professor Wallace, in the *Memoirs of the Royal Astronomical Society*, vol. ix. p. 185. The first of these solutions is as follows:—

1. Find x' , a first approximation to the eccentric anomaly x , by this formula,

$$\tan(x' - \frac{1}{2}s) = \frac{1+e}{1-e} \tan \frac{1}{2}s.$$

2. Find y such that

$$\tan(\frac{1}{2}x' + y) = \frac{1+e}{1-e} \tan \frac{1}{2}x'.$$

3. Find c , a correction of x' , so that

$$\sin(y-c) = \frac{\sin y}{\sin x'} \cdot \sin 1'' (x' - s).$$

(Here $x' - s$ must be expressed in seconds of a degree.)

4. Then the eccentric anomaly, $x = x' + c$. The computation of the eccentric anomaly by this method is extremely simple.

Keramohalite. A hydrated subsulphate of alumina having the same composition as Aluminite. It occurs in crystalline crusts and in six-sided tables near Königsberg in Hungary, associated with Iron Vitriol.

Keraphyllite. A species of Hornblende. [CARINTHINE.]

Kerargyrite (Gr. *κέρας*, a horn; *ἀργυρος*, silver). Native chloride of silver. [HORN SILVER.]

Kerasite (Gr. *κέρας*). A synonym of chloro-carbonate of lead. [CROMFORDITE.]

Kerate. [HORN SILVER.]

Keratonyxis (Gr. *κέρας*, a horn, *νύξ*, a puncturing). A term applied by the German surgeons to the operation of couching, performed by introducing a needle through the cornea or horny coat of the eye, and depressing or breaking the opaque lens.

Keratophyllite (Gr. *κέρας*, and *φύλλον*, a leaf). A mineralogical synonym of Actinolite.

Keri-chetib (Heb.). In Philology, the name given to various readings in the Hebrew Bible. Keri signifies *that which is read*, and chetib *that which is written*. When any such various readings occur, the false reading or chetib is written in the text, and the true reading or keri is written in the margin, with p under it. These corrections, which are about 1,000 in number, have been generally attributed to Ezra. (Kennicott, *Dissertation Generalis*.)

Kermes (Arab, *little worm*). An insect found in many parts of Asia and the south of Europe, the *Coccus ilicis* of Linnaeus. They were long taken for the seeds of the tree on which they live, and hence called *grains of kermes*. They

KERMES MINERAL

are used as a red and scarlet dye. Before the introduction of cochineal, kermes was the most esteemed drug for dyeing scarlet. The tapestries of Brussels and other parts of Flanders, which have lost little of their original brilliancy, even after a lapse of 200 years, were dyed with kermes. (Beckmann's *History of Inventions*; Bancroft's *Permanent Colours*.)

Kermes Mineral. A name given by the old chemists to the precipitated sulphide of antimony, in consequence of its reddish colour.

Kermesite. Native oxy-sulphide of antimony.

Kerned Letters. In Printing, those types which have their faces hanging over one or both sides of their shanks or bodies. In Greek, for example, where the vowels are almost always cast in this manner, the kerned η will admit all kinds of accents or breathings (each cast upon a separate piece of metal), and may become $\acute{\eta}$, $\grave{\eta}$, $\tilde{\eta}$, $\hat{\eta}$, $\check{\eta}$, $\circ\grave{\eta}$, $\circ\tilde{\eta}$, $\circ\hat{\eta}$, $\circ\check{\eta}$, $\circ\circ\grave{\eta}$, $\circ\circ\tilde{\eta}$, $\circ\circ\hat{\eta}$, $\circ\circ\check{\eta}$, as required by the printer.

Kerodon (Gr. $\kappa\eta\rho\acute{o}\nu$, a *heart*; $\delta\delta\acute{o}\nu$, a *tooth*). A genus of herbivorous Rodents, characterised

by $\frac{4-4}{4-4}$ molar teeth, each composed of two equal parts, of which the transverse section presents a cordiform or heart-shaped figure; the two parts are united on the external side in the upper, and on the internal side in the lower jaw. The incisors are two in number in both jaws, and present the form common to the Cavies, to which family the present genus belongs. The species are small, scarcely equalling the Guinea-pig in size. They are peculiar, with the other Cavies, to the South American continent.

Kerolite (Gr. $\kappa\eta\rho\acute{o}\varsigma$, *wax*, and $\lambda\acute{i}\theta\omicron\varsigma$, *stone*). A native hydrated silicate of manganese, which occurs in kidney-shaped masses of a white, yellow, or green colour, at Zöblitz in Saxony, Frankenstein in Silesia, and in Harford county, Maryland.

Kersey (probably a corruption of Jersey, whence it originally came). A kind of coarse cloth, usually ribbed, and woven from long wool. It is chiefly manufactured in the north of England. *Kersynure*, on the other hand, is a thin stuff, generally woven plain from the finest wools; and hence it has been inferred that these two terms, the meaning of which is so distinct, cannot be referred to the same origin. Kerseymere is said to have derived its appellation from Cashmir, a country which produces the finest wool and is celebrated for the works of its looms. In England it is principally manufactured in the western districts.

Kestrel. The *Falco Tinnunculus* of Linnaeus, one of the common English birds of prey.

Ketch (Dan. *kottsche*; Dutch, *kits*). An almost obsolete form of two-masted vessel, carrying a tall mainmast and shorter mizzen. It was a favourite form for yachts, and more especially for mortar-vessels.

Ketchup. A name of Eastern origin, said to come from kitjap, the Japanese name for some similar condiment. With us it is usually

KEY

prepared from mushrooms, champignons, and similar fungi, by sprinkling them, when broken up, with salt, and boiling the expressed juice with spice. Mr. Berkeley, one of our most learned fungologists, states, however, that the better plan is to let the juice strain without squeezing, and after standing for twelve hours to rack it off clear and bottle it, filling the top of the bottle up with alcohol, in which the proper spices have been previously steeped. Prepared in this way, it retains its peculiar flavour more perfectly than when boiled. Ketchup is often prepared for sale from agarics collected almost indiscriminately, no care being taken to discard poisonous species. The best ketchup is prepared from *Agaricus campestris*, but a very good quality may be obtained from an admixture of other species, especially *A. procerrus*, if care is used. Walnut ketchup, a similar preparation from green walnuts, is also of frequent use in domestic economy.

Ketones or Acetones. A term used by some chemists to designate a product of the dry distillation of the baryta, lime, or lead salts of the volatile acids. Amongst these products is a compound which has been termed the *kétone* of the acid, and which bears the same relation to the acid from which it has been obtained, as *acetone* does to *acetic acid*. [ACETONE.]

Keuper. The uppermost division of the *Trias* of continental geologists. It consists generally of a series of variegated marls (*marines irisées*), of red, grey, or blue colour, passing into green marls, black clay, and fine-grained sandstones. Rock-salt and gypsum abound in these deposits, and the upper members of the new red sandstone of Cheshire and other parts of England are also characterised by the presence of the same minerals.

The Keuper contains not unfrequently remains of plants distinct from those of the coal measures, and even from those of the *Bunter sandstein*, the lowest division of the *Trias*.

Kevels (called also *Ranges*). On Ship-board, timbers projecting at a small angle from the sides, to which are belayed the sheets and tacks by which the mainsail and the fore-sail are extended. *Kevel heads* are the ends of certain top timbers which, projecting above the ordinary line of gunwale, form bitts round which ropes can be made fast.

Key (A.-Sax. *cæg*). In Architecture, a piece of wood let into the back of another in the contrary direction of the grain, to preserve the last from warping. The term is also applied to the portion of lime and hair rendering that forces its way between the joints of the laths, in plasterer's work, and serves to uphold the body of the work.

Key or Key Note. In Music, the principal or fundamental note in a composition, on which frequent closes or cadences are made. It is that in which the piece usually begins and ends, and is, as it were, the musical standard to which regard must be had in all the other combinations of sounds in the composition, and

KEY STONE

under whose influence they are. [TONIC.] The key of a composition may be either major or minor, according as the scale has a major or a minor third.

Key Stone. The middle voussoir of the arch of a bridge, or the arch stone at the crown or immediately over the centre of the arch. The length of the key stone, or thickness of the archivolt at the top, is usually made about $\frac{1}{12}$ or $\frac{1}{10}$ of the span by the best architects. The practice of engineers is rather different; it is based upon the empirical formula derived from Perronet's experience, in which, calling e the thickness, then

$$e = 0.0347 d + 0 = 325;$$

d representing the span if the vault be semi-circular, and double the radius if the vault be over the centre. The dimensions above quoted are in mètres.

Key-board. In Music, the series of levers in a keyed instrument, as a pianoforte, organ, or harpsichord, upon which the fingers press to produce percussion of the strings, or in the organ the opening of valves. It consists of short black and long white keys.

Keyser's Pills. A once celebrated mercurial preparation, the active ingredient in which is the *acetate of mercury*.

Khalif. [CALIPH.]

Khan. In Persia, properly speaking, the title of an officer or governor, added after his name. The sovereigns of many independent states of Northern Asia are styled *khans*. Khan is frequently used by our own countrymen to signify an Eastern CARAVANSERA [which see]; in which travellers find a gratuitous lodging, provided their stay be limited to a single night.

Khat. [KAT.]

Khay. A Senegal Cedrelaceous tree, called *K. senegalensis*, the bark of which is used as a febrifuge on the banks of the Gambia, and the wood of which resembles mahogany. It is, in fact, closely allied to the mahogany-tree, *Swietenia Mahagoni*.

Khotbah (Arab.). A peculiar form of prayer used in Mohammedan countries at the commencement of public worship in the great mosques on Friday at noon. It was originally performed by the Prophet himself, and by his successors till the time of Mohammed VIII. (A. D. 936), who appointed special ministers for the purpose, on which footing it has continued to the present time. The khotbah is chiefly a 'confession of faith,' and a general petition for success to the Mohammedan religion. It is divided into two distinct parts, between which the officiating khatib or priest makes a considerable pause, and is regarded by the Mohammedans as the most solemn and important part of their worship. The insertion of his name in this prayer has always been considered one of the chief prerogatives of the sultan of Turkey.

Khus-khus or **Cuscuta**. The fragrant Indian grass *Andropogon muricatus*.

name (Gr. *κισσηλος, spurious*) or

KILLINITE

Axotomous Iron-ore. A slightly magnetic titaniferous iron-ore from Gastein.

Kidnapping (a word of doubtful origin: Mr. Wedgwood refers it to nab=*steal*, and kid [slang]=*child*). In Law, the forcible abduction of anyone from his own country into another. It is an offence at common law. By 11 & 12 Wm. III. c. 7, penalties were denounced against masters of vessels having on board persons who had been kidnapped against their will. This enactment was probably occasioned by the practice, not uncommon in those days, of carrying away by force or fraud labouring persons to serve in the plantations in America. This clause is repealed by 9 Geo. IV. c. 31, by which masters of vessels are made punishable for leaving abroad any of their men against their will, an offence now punishable under stat. 17 & 18 Vict. c. 104 s. 206. The stealing of children away from persons having the lawful custody of them (popularly termed *kidnapping*) is felony under stat. 24 & 25 Vict. c. 100.

Kidneys. The organs in which the urine is secreted: there is one on each side in the loins, near the first lumbar vertebra, and behind the peritoneum. The pelvis of the kidney terminates in the ureter, and is divided into several portions called *calyces*, into each of which a papilla projects, through the minute orifices of which the secreted urine passes into the cavity called the pelvis, and thence by the ureter into the bladder. [RENAL ORGANS.]

Kiesel Schiefer (Ger.). A peculiar silicious schist of the lower division of the upper carboniferous series of the Rhine is thus named. This schist is often black and loaded with carbon. It is found in other countries not unfrequently in the same state and association.

Kieserite. A sulphate of magnesia found at the Stassfurth salt mine, near Magdeburg.

Kigelia (Mozamb. Kigelikeia). The name of a genus of African *Crescentiaceae*, the only species of which, *K. pinnata*, is a large spreading tree, with pinnate leaves, and long pendent fruit. The latter, when roasted, are used as an outward application in rheumatic complaints; and the tree itself is held sacred in Nubia, the negroes celebrating beneath it those religious festivals which take place by moonlight.

Kikokuemalo. A resin, resembling copal brought from America, where it is used indiciually. It forms excellent varnishes.

Kilbrickenite. A bluish-grey variety of sulphide of antimony and lead, found in Ireland at Kilbricken, Clare county.

Kilkenny Coal. [ANTHRACITE.]

Killas. A Cornish name for the clay slate which forms what is called in mining language the *country*, in those parts where mineral veins are worked. The name is applied very indefinitely by miners, and has no strict geological use or meaning.

Killinite. A mineral, sometimes described as a variety of Spodumene, from Killiney, near Dublin. It is a hydrated silicate of alumina, containing potash and oxide of iron.

KILOGRAMME

Kilogramme. A French measure of weight equal to 1,000 grammes, and to 2·2046 lbs. avoirdupois.

Kilomètre. A thousand mètres; equal to 1,093½ yards nearly.

Kilt. A loose dress, extending from the waist to the knee in the form of a petticoat; worn in the Highlands by men, and by children in the Lowlands. The term is, according to Jamieson, unquestionably Gothic. The Highlanders designate the kilt as the *filib g.* This singular national dress is fast hastening into disuse; and but for a few Highland regiments in which it is still maintained, it would probably long ago have been universally superseded by the dress of the Lowlanders.

Kimeridge Clay. A blue slaty clay, containing carbonate and sulphate of lime. It is a thick and important deposit in the south of England, where it forms the base of the upper division of the oolites, and contains a bituminous shale called the Kimeridge coal. In France, there is a corresponding bed of clay at Honfleur, at the mouth of the Seine. In the north of Bavaria the celebrated lithographic slates of Solnhofen replace the clays. A small oyster called the *Gryphæa virgula* is very characteristic of this part of the oolitic series. The Portland beds overlie the Kimeridge clay.

Kimeridge Coal. A remarkably bituminous shale, found in the Kimeridge clay beds on the south coast of England. It is of dark brown colour and without lustre, it effervesces slightly with acids, contains no iron pyrites, and burns readily with a yellowish, rather smoky and heavy flame. It is associated with slaty pyritous clays. It has been used for burning with little advantage. It would probably better repay distilling, were it not for the disagreeable odour of the oil obtained from it.

Kinematics (Gr. *κίνημα*, a motion). The science of pure motion. It differs from geometry by the admission of the conceptions of time and velocity, and from dynamics proper by the exclusion of the conception of force as a cause of motion. Roberval's method of tangents and Newton's fluxions are purely kinematical methods. From the kinematics of a point all the properties of curves may be deduced, and that frequently with great simplicity. A curve, in fact, may be conceived to be generated by a point moving along a line which at the same time incessantly turns around that point, a definition by which Lamarle has profited in his *Théorie Géométrique des Rayons et Centres de Courbure* (*Bulletins de l'Acad. Roy. de Belgique*, tomes 2, 3, 5, 6, also *Exposé Géométrique du Calcul Différentiel et Intégral, précédé de la Cinématique du Point, de la Droite et du Plan*, Paris 1861). The line is the tangent of the curve, and the relative velocities of translation and rotation determine its curvature.

The motion of a rigid body or of an invariable system of points is determined, of course, by that of any three points, or of the plane containing these three. Now, by the theory of

KING

rotations [ROTATIONS, COMPOSITION AND RESOLUTION OF] any position whatever can be given to such a plane, by imparting to it a helical motion around a given axis, the *central axis*.

Further, the motion of such a plane at any instant may not only be regarded as consisting of a simultaneous sliding along, and rotation around the central or, as it is often called, the *instantaneous sliding axis*; it is also equivalent to two simultaneous rotations, without sliding, around two axes which do not intersect one another, and to which the name of *reciprocal* or *conjugate lines* has been given. The number of pairs of reciprocal lines having the above property is infinite; one line, however, being chosen arbitrarily, the other is perfectly defined. The mutual inclination of two such reciprocal lines varies from zero to a right angle, and amongst the pairs at right angles to each other, one always lies in the plane under consideration, of which it is called the *characteristic*, and the other cuts the plane perpendicularly in a point to which the name of *focus* has been given. These terms were introduced by Charles, whose memoirs on the subject in the *Comptes Rendus de l'Acad. des Sciences*, 1843, are well worthy of study. The first is obviously in accordance with Monge's definition of a characteristic, since it is the line common to two consecutive positions of the moving plane.

King. A title of dignity in the languages, extinct and living, of the Teutonic and Gothic races. There is some difference of opinion as to the origin of the word; probably as *kon-ung*, *cyn-ing*, it expresses one chosen from the people to rule them, the termination appearing in such words as ætheling, while the first syllable, connected with the Greek *γενος*, Latin *gens*, &c., appears also in *ynst* and *quean*. It would therefore primarily mean one chosen from and by the people to represent and guide them; but it has passed through as many shades of meaning as there are states or nations to be governed. Thus it is applied equally to the constitutional sovereign of England and the absolute sovereign of Prussia; to the chief magistrate of Poland in former times, who was *elected*, and to that of England, who succeeds by *hereditary* right; to the head of a savage tribe or barbarous horde, as well as to that of the most refined and civilised nation. It is expressed in Greek by the word *basilens*, and in Latin and its cognate languages by *rex*; but all the nations of Europe have adopted into their respective languages the equivalent terms in use among the people with whom they carry on intercourse. Thus we speak of the Shah of Persia, the Grand Sultan, the Pasha of Egypt, the Dey of Algiers, &c.

In countries where the kingly office is hereditary, some form has always been gone through on the accession of a new king, in which there is a recognition on the part of the people of his right; a claim from them that he should pledge himself to the performance of certain duties; and generally a religious ceremony performed, in which the

KING CRAB

anointing him with oil and placing a crown upon his head are conspicuous acts; the whole solemnity being styled the coronation. In modern Europe the Pope and the Emperor assumed as a joint prerogative the right of conferring the dignity of king. Frederick I. of Prussia was the first sovereign who assumed the title, and had it acknowledged by the other states of Europe without their authorisation.

In Great Britain, the king exercises the supreme executive power, together with a share in the legislative authority jointly with the two houses of parliament. [PARLIAMENT.] The right to the throne of England (now extended to Great Britain and Ireland) is hereditary, subject to the authority of parliament to limit the succession. This was last done by the stat. 12 & 13 Wm. III., when it was fixed in the heirs of the electress Sophia of Hanover, being Protestants. The duties of the king according to the constitution are embodied in the coronation oath, fixed by stat. 1 Wm. & Mary. Incidental prerogatives are legal exceptions in favour of the crown where its claims clash with those of a subject; relating to such matters as descents of lands, debts, &c. The direct prerogatives of the crown are those which attach to the king in respect of his political authority: such as the sanctity of his person; his prerogatives as head of the executive; the power of making war and peace; treaties with foreign powers; military and naval command; the supreme dispensation of justice through his courts; the power of erecting and disposing of offices and honours; the power of issuing proclamations binding on the subject in certain cases, with the advice of his privy council; and, lastly, the supreme government of the national church. The king's revenue is of two sorts, ordinary and extraordinary. The ordinary revenue or patrimony is such as either has subsisted in the crown time out of mind, or has been granted by parliament in exchange for such. [CIVIL LIST.] The extraordinary revenue consists of the supplies annually granted by parliament. [PARLIAMENT; PREROGATIVE.]

King Crab. [LIMULUS.]

King Fish. A name sometimes applied to the *opah* (*Lampris guttatus*, Retz.).

King Post. In Architecture, the middle post of an assemblage of trussed framing, for supporting, or rather for suspending, the tie-beam, at the middle, and at the lower ends of the struts. In framed partitions the king post is introduced in the centre of the span, and has the discharging pieces framed into it in either side.

King's Advocate. The Advocate representing the crown in the Ecclesiastical and Admiralty Courts.

King's or Queen's Bench, Court of. In Law, this court originated in the ancient Aula Regia, in which the king was accustomed (as he still is supposed in the King's Bench by fiction of law) to sit in person, and which followed him in all his progresses. The judges of the court of King's Bench, as well as of the other superior courts, formerly varied in number according to

KING'S BENCH

the royal discretion. At a later period they were reduced to four; now increased, by stat. 1 Wm. IV. c. 70, to five—the chief justice, who

preside or *younger* judges. THE COURT OF KING'S Bench, besides those branches of its jurisdiction which it has in common with the other two superior common law courts [COURTS, SUPERIOR], has also peculiar authority, or presents more advantages in some particular proceedings.

It is the preferable although not the only tribunal for discharging prisoners under the Habeas Corpus Acts. It has control over all inferior courts by means of the process called *certiorari*, which is a writ sued out of this court, by virtue of which proceedings may be removed into it out of such inferior jurisdiction, whether in criminal or civil cases. It has also an exclusive authority (except in a few cases) to compel all inferior courts and officers, and in some instances private persons, to perform acts of a public nature, and connected with a public duty. By means of a *prohibition* it can restrain all other courts from proceeding where they exceed or misuse their jurisdiction: this is likewise a writ directed to the judge and the plaintiff in the inferior court. A writ of error in law from all inferior courts is, with certain exceptions, returnable in the King's Bench. This court likewise hears and determines cases stated by courts of sessions. The greater proportion of these are questions on the validity of poor's rates, or on parol settlements. When a court of sessions entertains a doubt on a point of law arising in the argument, it will usually authorise the party against which it decides to have the judgment thus reviewed, the cases being stated in writing. The criminal jurisdiction of the King's Bench is still extensive. It has, at common law, jurisdiction by indictment over every species of criminal offence committed in Middlesex; and in practice misdemeanours, as conspiracies or perjuries, committed in the county, are still indicted in this court, and tried after term at nisi prius among the civil causes. Sometimes also trial at bar, or by the full court, is granted on special application. It has also jurisdiction by criminal information, which lies in cases of misdemeanour only; a proceeding which supersedes the necessity of an indictment found by a grand jury. An information is filed either by the attorney-general *ex officio*, as it is termed—a proceeding generally adopted in certain misdemeanours of a public nature; or at the suit of a private party by leave of the court.

An information in the nature of a *quo warranto* is in form a criminal, but substantially a civil proceeding. It is granted where any subject or body politic has assumed a franchise or privilege not being legally entitled, and to the injury of some other party or the public. Any indictment, presentment, &c. found in any part of England, may be moved by *certiorari* into this court; as may be also all convictions or orders of justices of the peace, unless where such appeal is prevented by particular statutes.

KING'S EVIL

King's Evil. Scrofula attacking the glands, respecting which a superstitious notion long existed that it was curable by the touch of royalty.

King's Yellow. A pigment, the basis is *orpiment*, or yellow sulphuret of arsenic.

King-at-Arms. An officer of great antiquity, and formerly of great authority, whose business is to preside over the chapters, and to direct the proceedings of heralds. The origin of this office is involved in obscurity. There are three kings-at-arms in England—Garter, Clarenceux, and Norroy; the first of whom is styled *principal king-at-arms*, and the two latter *provincial kings*, because their duties are confined to the provinces. The name Clarenceux is said to be derived from Clarence, brother of Henry V., first king-at-arms for the south of England; that of Norroy (Norman-French for *northern king*) is self-explanatory. There is also a Lyon king-at-arms for Scotland, as well as an Ulster king-at-arms for Ireland, whose duties are nearly analogous to those of England. (Noble's *History of the College of Arms*.)

Kingfisher. [ALCEDO; HALCYONIDÆ.]

Kingston. A name sometimes given to the angel-fish (*Squatina angelus*, Dunn.).

Kinic Acid. The acid with which quinia and cinchona are combined in yellow and pale Peruvian bark. [CINCHONIC ACID.]

Kink. In a rope or chain, a curvature reduced to a sharp bend by the too rapid drawing from a coil or twist. It is very dangerous on shipboard, causing a stoppage in the run of tackle through blocks, and weakening the rope by a sudden reversal of the direction of the strain. The best rope kinks very seldom.

Kinkajou. The native name of a Plantigrade quadruped of South America, of arboreal habits, with a long prehensile tail, a short muzzle, and a thick coat of woolly hair. It forms the type of the genus *Potos* of Cuvier, which name Illiger changed to *Cercoleptes*. Only one species is well established, the *Cercoleptes caudivolvulus* of Illiger.

Kino. An Indian word applied to certain astringent vegetable extracts. The finest kino is in brilliant fragments of a deep brownish red colour, and highly astringent; it contains tannin, gum, and extractive matter, and is used in medicine as an astringent. Indian kino is said to be the produce of *Pterocarpus Marsupium*; and African kino that of *Pterocarpus crinacrus*. The inspissated juice of *Eucalyptus resinifera* is sometimes called Botany Bay kino.

Kinone. *Kinöl.* An organic substance in golden-yellow crystals, produced when kinic acid is distilled with peroxide of manganese and sulphuric acid. Kinone has also been found among the products of the dry distillation of coffee.

Kiosk. A Turkish word, signifying a kind of open pavilion or summer house, supported by pillars. These ornaments have of late years been introduced to a considerable extent into the gardens of European countries.

KITE

Kirk (Ger. kirche). A Scottish term synonymous with *church*, and used chiefly to designate the form of religion established in that country. [PRESBYTERIANISM.]

Kirk Session. The lowest ecclesiastical court of the kirk of Scotland. It is composed of the minister of the parish and of lay elders. It takes cognisance of cases of scandal, of the poor's fund, and of matters of general ecclesiastical discipline. There is an appeal from its decisions to the presbytery.

Kirschwasser (Ger. *cherry water*). An alcoholic liquor obtained by fermenting the small and sweet black cherry. The liquor produced is distilled, and often flavoured with hydrocyanic acid, derived from the bruised kernels of the fruit; this gives to kirschwasser, when sweetened, the character of *noyau*.

Kirwanite. A hydrated silicate of alumina, lime, and protoxide of iron—probably a variety of Green-earth. It occurs in small nodules of a dark olive-green colour, with a fibrous and somewhat radiated structure, in the basalt of the Mourne Mountains on the north-east coast of Ireland. Named after Richard Kirwan, the mineralogist.

Kish. A substance occasionally produced in iron smelting furnaces; in appearance it resembles plumbago, but is said to consist chiefly of carbon and manganese.

Kistvaen. [CESTVAEN.]

Kit (Dutch, *a back load*). The clothes and personal appointments of a soldier. Every recruit, upon being finally approved, receives a free kit, including all those articles known as regimental necessaries, which he is bound to keep constantly complete and in good order.

Kit Cat Club. The name of a celebrated association, instituted about 1688 by 'some young men of wit and pleasure about town,' originally for convivial purposes; but as its most distinguished members were Whigs in politics, it gradually assumed a political character, till in the reign of Queen Anne it came to be regarded as exclusively political in its objects. At that period it comprised above forty noblemen and gentlemen of the first rank and fortune, firm friends to the Hanoverian succession; among whom were Addison, Steele, Marlborough, Walpole, &c. &c. It was originally formed in Shire Lane, and derived its name from one Christopher (Kit) Kat, who supplied the members with mutton pies. The fame of this club has been transmitted chiefly by the collection of the portraits of the members painted by Sir Godfrey Kneller, himself a member, who was obliged to invent a new-sized canvas accommodated to the height of the walls; whence has originated the application of the epithet *kit cat* to any portrait about three-quarters in length. It was dissolved in the year 1720. (*Quarterly Review*, vol. xxvi.)

Kite (Welsh *cád*). The native bird so called is a species of the genus *Milvus*, separated by Bechstein from the genus *Falco* of Linnæus on account of the forked tail, length of wings, and the short and weak beak and feet in

KITE

proportion to the size of the body. This deterioration of their destructive instruments renders the kite the most cowardly of the birds of prey. The common kite, or glade (*Milvus vulgaris*), preys chiefly on the smaller quadrupeds and birds, young chickens, &c.; yet the courage of the mother hen renders her more than a match for the robber, and she generally repels his attacks on his favourite prey. The female lays two or three eggs of a whitish colour, spotted with pale yellow, and of a roundish form.

The term *kite* is applied in some places, as Devonshire and Cornwall, to the brill (*Rhombus vulgaris*).

KITE. A well-known toy; first employed by Romas in France, and Dr. Franklin in America, to elevate a conductor into a thunder-cloud, whereby the identity of lightning with the electric spark was ascertained. It is formed of a slender frame of wood and pack-thread, rounded at one end and terminating in a point at the other, resembling in some measure a cross-bow, and covered with paper. A long string is attached to the frame, near its centre of gravity, by which it is held in the hand. In order that the kite may be capable of being raised, it is necessary that its flat surface be presented obliquely to the direction of the wind; a string or *tail*, carrying some light substance, is therefore attached to the sharp end of the frame, and serves by means of its gravity to maintain the proper inclination. The force of the wind, impinging obliquely on the surface, is resolved into two parts, one perpendicular and the other parallel to the surface; the first of these parts is counterbalanced by the tension of the string held in the hand, and the second is expended in elevating the kite. The position in which the wind acts with the greatest effect is when the perpendicular to the surface is inclined to the direction of the wind (that is, to the horizon) in an angle of about $54\frac{1}{2}$ degrees.

Kitt Composition. A material composed of: resin 7 lb. 8 oz., pitch 6 lb. 14 oz., beeswax 6 lb. 14 oz., tallow 1 lb. 14 oz., boiled together over a slow fire. It is used to render canvas waterproof. It is not permeable to water, and sticks firmly to metallic substances.

Kittool or Kittul. Cinghalese names for the strong fibre obtained from the leaf-stalks of the palm called *Caryota urens*.

Kivi-kivi. The native name of the New Zealanders for their singular bird the *Apteryx australis*. [ARTERYX.]

Klaprothine. A name for Lazulite, after the celebrated German chemist, Klaproth.

Klinometer (Gr. κλίμα, *I incline*; μέτρον, *measure*). An instrument for measuring the angles of the dip of strata.

Knaurs. In Botany, the knots or tumours sometimes found on the stems or roots of plants.

Knebelite. A mineral from an unknown locality, named after Major von Knebel. Probably it is a ferruginous Tephroite, or silicate of iron and manganese.

KNIGHT

Knee (Gr. γόνα, Lat. genu, Ger. knie). In Architecture, a naturally or artificially bent piece of timber, on which another is received to relieve a weight or strain; the term is also applied to wrought-iron knees, for the same purpose.

KNEE. In Shipbuilding, an angle, formerly of timber, but in modern times nearly always of iron, for bracing together internally parts which form angles with each other. The principal knees are those supporting the beams, and fastened to them and to the ribs. There are, however, various other knees in different parts of the ship. They tend to bind the whole vessel into one hollow body, in which the parts are mutually dependent. The *knee of the head* sustains the figure-head and the projecting bow above the water-line: it is braced on to the stem.

Knee Pan. A small flat heart-shaped bone placed at the fore part of the knee joint. It is an important defence to that large joint, and also serves to increase the powers of the muscles which extend the leg. It is attached by a strong ligament to the upper end of the tibia.

Kneph. The ram-headed god of ancient Egypt, known by the name Amen-ra, or, in its Greek form, Ammon [which see].

Knight, Knighthood (A.-Sax. cniht, Ger. knecht, a *lad*; hence a *man-at-arms*: cf. INFANTRY). According to Tacitus and other writers, the ancient German kings and chiefs were attended in war and peace by a select body of faithful companions. Kings, great thanes, and aldermen had each among the Anglo-Saxons their attendant cnihts or military servants, who owed them a species of fealty rather personal than territorial. But the order of knighthood, in the more recent sense of the word, was introduced among us from France. Among the French and Germans, indeed, the order of knights was designated by another name—*chevalier* or *ritter*, from their serving on horseback in battle, and holding a rank above the footmen. But the Norman chevalier so completely answered to the Saxon cniht in the peculiar attribute of being personally attached to the military service of some chieftain, that the English appellation was soon in general use, as if to express the same meaning conveyed by the French title, and by its Latin equivalent *miles*. The Anglo-Saxons appear, indeed, to have occasionally practised long before the Conquest some ceremonies resembling those which became usual in later times on the creation of a knight; thus Alfred is said to have honoured Athelstan by the gift of a belt and robe, and by girding him with a sword.

It is said in general, but on doubtful evidence, that knighthood had become an established institution in the eleventh century; but that the characteristic which belonged to it in later times, of being restricted to men of noble birth, did not become general until the fourteenth. The privilege of conferring knighthood seems to have belonged originally to the sovereign, and to have been retained as his prerogative in

KNIGHT

all European constitutions, although frequently delegated to or usurped by high feudatories, generals of armies, &c. In later times, and when knighthood had assumed its peculiar romantic character, the most distinguished and valorous knights were allowed to confer it, and kings themselves sought for the distinction of knighthood at their hands.

It was common to create knights on various occasions. The most honourable species of knighthood was that conferred on the field and after a battle; but the more common fashion, especially in France, the parent country of chivalrous institutions, was to make knights when a battle was expected. Five hundred were created at once in the French army before the battle of Agincourt. Knights were also created on other solemn occasions; as great festivals, coronations, princely marriages, &c.

In describing the ordinances of knighthood as they existed when that institution was brought to the point of imaginary perfection, the period to which we must refer is the fourteenth century; and the countries chiefly France, Germany, and England. In Italy and Spain, and generally in other parts of Christendom, the chivalrous customs of the first-named regions were imitated, but do not appear to have grown up spontaneously as part of the popular usages. Before this epoch, indeed, the Crusades had communicated to the institution much of its religious character; and the poems of the Troubadours and Trouveurs attest how much of gallantry had already been fancifully interwoven with the military habits of the age. But it was not, perhaps, until the time when the favourite fictions of romance had begun to act strongly on the popular imagination, that the ideal usages of chivalry were completely engrafted in practice on the substantial institution of knighthood. [CHIVALRY.]

The orders of chivalry were three. The future knight was first educated, in general, as a page attached to the family, and especially to the ladies of some noble house: when of full age, he became a squire (*écuyer*). The proper office of the squire, in the theory of chivalry, was, as his name of *shield-bearer* denotes, to attend on the person of a knight, to whom he was bound to render devoted and faithful service. In this capacity he was a sort of apprentice to knighthood; but as many esquires never reached the order of knighthood at all, but remained independent, the rank of esquire, in ordinary usage, became an intervening order between the knight and the simple gentleman: in which sense it is still retained in England. The order of knighthood followed this double probation. Knights, however, were often made without having passed regularly through the intervening stages; and even in the age of chivalry, the honour was occasionally conferred on mere children; although his was an evident abuse, and regarded as such. When the order of knighthood was conferred with full solemnity in the leisure of a court or city, imposing preliminary ceremonies were required of the can-

didate. He prepared himself by prayer and fasting, watched his arms all night in a chapel, and was then admitted with the performance of religious rites. Knighthood was conferred by the *accolade*, which, from the derivation of the name from the Latin *collum*, *the neck*, would appear to have been originally an embrace; but afterwards consisted, as it still does, in a blow of the flat of a sword on the neck of the kneeling candidate. The oath of knighthood was previously administered. This oath contained at different times various fanciful clauses: in France there were twenty vows comprised in it.

Knighthood was an institution which served in some respects as a compensation for the inequalities of rank incident to the feudal system. All knights, from the king to the lowest bachelor, were brethren of the same order; and when chivalry was in its most flourishing state, it may almost be said that they were all of the same country. National distinctions had little place between knights, who were enemies only in time of warfare, owing to their feudal duties, which attached them to the banner of a particular king or suzerain. At tournaments, court festivals, &c., in time of peace, knights of all nations were admitted indifferently; and the candidate for knighthood sought that honour at the hands of the most distinguished name in chivalry rather than of a countryman. The chief distinction of rank which subsisted between knights, in France and England, was rather of a feudal than a chivalrous character; it was that of knights-bachelors and knights-bannets. The knight-bachelor was of the lower order. His name has been variously derived. [BACHELOR.] But in the more chivalrous times (as in all later periods) this honour was conferred without any reference to a qualification of property. Many knights-bachelors were, in fact, mere adventurers, unconnected by feudal ties of any sort, who offered their services in war to any successful leader, and who found in their sword a means of subsistence, not only by pay and plunder, but by the regularly established system of ransom which every knight taken in action paid for his liberty. The *chevalier-bannet* was one who possessed fiefs to a greater amount, was obliged to serve in war with a greater attendance, and carried a banner. Under Charles VII. the bannets of France made remonstrances against the services required of them, on the ground of their impoverishment by the English wars; and it appears that this order fell afterwards into disuse in that country. In England the distinction appears to have been of a somewhat different character. The *knights' fees*, into which England was divided by the Conqueror, were such portions of land as could maintain a simple knight or bachelor; and by a statute of Edward II. persons who had the amount of 20*l.* a year in fee, or for life, were obliged to take this order of knighthood. This statute grew into disuse, except when occasionally put in force, as it was for the last

KNIGHT

time under Charles I., as a means of extorting money, by way of fines, for not taking up the order. Bannerets, on the other hand, in England appear to have been such knights as were made or promoted from the lower degree on the field of battle. [BANNERET.] The distinction in the field between the different orders of chivalry was, at least at one period, the following: The esquire bore the *pennoned* or triangular streamer; the knight-bachelor the *pennon* or forked streamer (swallow-tailed), made by dividing the end of the pennoncel; the banneret a banner (which was in strict usage of an oblong shape, barons being entitled to the square banner). Thus, when a banneret was made on the field, the ceremony was accomplished by cutting off the forked end of his pennon and converting it into a banner. Common knights and esquires were then under his command.

The confinement of the order of knighthood to men of noble birth (on the Continent, for the strict line of demarcation between nobility and commonalty was never accurately drawn in England), although necessary in theory to the completion of the chivalric system, tended in practice to its decay. Knighthood, after the fourteenth century, became more and more an honorary distinction, to which birth alone gave a title, and which was not considered to represent any actual duty or service; and finally, through various steps, it became again a mere personal distinction, which it was part of the sovereign's prerogative to confer, either on military persons or any others; and by the multiplication of orders, for admission into which nobility of birth was not always a necessary qualification, this peculiar property of the knightly order became again effaced. There are, however, in most Continental countries, several orders into which nobility still constitutes a necessary title for admission.

Orders of knighthood are of two classes: either they are associations or fraternities possessing property and rights of their own as independent bodies, into which knights are admitted as members into a religious foundation; or they are merely honorary associations, established by sovereigns within their respective dominions, consisting of members whose only common tie is the possession of the same titular distinction. To the former class belonged the three celebrated religious orders founded during the Crusades—*TEMPLARS*, *HOSPITALIERS*, and *TEUTONIC KNIGHTS* [which see]; which were societies, not belonging to any particular crown or realm, possessed of extensive property, and acting in some respects as independent republics. Several of the Spanish and Portuguese orders of knighthood partake of both characters: they were originally religious, but have become secular. The kings of those countries, as *grand masters*, exercise the privilege of admission, and make use of it as a means of conferring distinction; but the knights as a body form an independent society possessed of property and privileges [ORDERS OF CALATRAVA, ALCANTARA, &c.] The other class, con-

KNIGHT'S FEE

sisting of orders merely titular, embraces most of the European orders, including all those of our own country. These were probably founded in imitation of the great military societies; although antiquarians have traced real or imaginary orders of knighthood under the reigns of princes of much more remote date, as Charles Martel, Charlemagne, &c. But these accounts are apocryphal: and no subsisting order of knighthood is of the date of the Crusades, except a few of those in Spain and Portugal, which, as we have said, were framed on the model of the great societies first mentioned.

Knight Errant. In the language of Chivalry, a knight wandering in search of adventures, sometimes under vows, for a certain period. Knight errantry was not altogether a fiction of romance. It originated, as Mr. Turner says, partly from the frequency of private war in feudal times, which made military aid constantly acceptable to the great barons; and as a knight had, for the most part, no other tie to the soil than his duties towards his feudal superior, he was at liberty to follow his own bent whenever his services were not needed by him. Such a mode of life peculiarly suited the tastes of the men of that age, and in some degree served the exigencies of society. 'Knights, therefore, were perpetually errant, or travelling in quest of adventures or employment; some from the pleasure of the expedition, and some for its expected profits. They often met the oppressed or the unsuccessful, and they cheerfully engaged themselves to redress those wrongs which laws were too feeble to remedy, and for redressing which, honour, plunder, or rich donations became usually their compensation.' (Turner's *History of England during the Middle Ages*, ch. xiii.)

Knight Service. *Servitium Militare*. The tenure by which a knight held his land. [FEUDAL SYSTEM.]

Knight of the Shire. The designation given to the representative in parliament of English counties at large, as distinguished from such cities and towns as are counties of themselves (which are seldom if ever called shires); and the representatives of which, as well as the members for other cities and towns, are called *citizens* or *burgesses*. It was formerly imperative on knights of the shire, as well as their choosers, either to be resident or to have a household in the county; but this regulation, which had long fallen into disuse, was formally repealed by 14 Geo. III. c. 58.

Knight's Fee (Low Lat. *Feodum Militare*). In the language of English feudal usage, a portion of land held by custom sufficient to maintain a knight to do service as such for the king. William the Conqueror by his military grants is said to have created 60,000 such fees. But although William's vassals were undoubtedly bound to follow him to war, it is doubted by modern antiquarians whether feudal services, strictly so called, were attached to these grants by the Conqueror, or whether they were not peculiarities arising subsequently when the

KNIGHTHEADS

feudal system grew into vigour, and attributed to the Conqueror by the legists of later times.

Knighthead. In Shipbuilding, the first cant timbers on each side of the stem. They serve to form a bed for the reception of the bowsprit.

Knoll (A.-Sax. *cnolle*, Ger. *knollen*). A term used in many parts of England for the pinnacle of a small hill, or for the hill itself.

Knoppern (Ger.). A species of gall-nut or excrescence formed by the puncture of an insect upon several kinds of oak. They are flat, hard, and prickly; they abound in Croatia, Styria, Slavonia, and Nativolia, and are used in Austria and Germany for tanning and dyeing.

Knot. In Sea language, a geographical mile. It is also 120 times the distance between two knots on the log line. A knot is to a statute mile nearly as seven to six. [Loc.]

Knots. The fastenings of ropes or cords; the union of ropes by interweaving. The most useful knots are: 1. *Thumb or over-hand knot*, tied at the end of a rope to prevent it from

KOBOLD

bind or draw anything close; 5. *Sheepshank*, serving to shorten a rope without cutting it or unfastening the ends; 6. *Clove hitch*, which binds with excessive force, and by which alone a weight can be hung to a smooth pole; 7. *Timber hitch*, very useful in hauling to move a weight; 8. *Single bowline knot*, difficult to undo, useful to throw over a post, &c., to haul on, used for the draw-loop of a slip noose; 9. *Double bowline knot*, for slinging a cask; 10. *Running bowline knot*; 11. *Wooding or packing-stick hitch*, used to tighten ropes; 12. *Men's harness hitch*, passing over the shoulder and under the opposite arm of men drawing a carriage, &c.; 13. *Stopper hitch*, for stoppering the fall of a tackle, &c.; 14. *Inside clinch*, for fastening a cable to the anchor ring, &c.; 15. *Common or sheet bend*, a very secure method of joining two ropes, or fastening a rope to a loop; 16. *Hawser bend*, for joining two ropes, easily undone; 17. *Cat's paw*, the turn in the bight of a rope, for hooking a tackle to it; 18. *Drag rope or lever hitch*, used for fixing handspikes or capstan bars to the ropes attached to heavy carriages, &c., which have to be moved by men; 19. *Half hitch*, cast on the bight of a rope; 20. *Carrick bend*. A wall-knot is a knot made at the end of a rope to prevent it from passing through a hole.

A special committee of the Alpine Club report, on the subject of knots: 'There can be no doubt that every knot in a rope weakens its power of resisting a sudden jerking strain. . . . These ropes, which we report will resist the strain of fourteen stone falling eight feet, will not resist it if there is a knot in any one of them, or even if the knots used in attaching them to the point of support or to the weights be roughly or carelessly made. . . . We therefore conclude that: 1st. No knot which is not absolutely necessary ought to be allowed to remain on the rope; 2nd. The tighter and harder a knot becomes, the worse it is; 3rd. The more loose and open a knot is made, the better it is.' See *Alpine Journal*, No. 7, September 1864, where diagrams are given of the knots recommended by the above-named special committee.

Knout, The. An instrument used in the infliction of a well-known Russian punishment.

Koala. The native name of a Marsupial quadruped of New Holland. [*PHASCOLARCTOS*.] The Mahrattas apply the same name to the jackal.

Kobellite. A mineral resembling Antimony Glance in general appearance, but with a brighter lustre and a radiated structure. It is a sulpho-bismuthate of lead, in which part of the lead is replaced by iron and copper. It is found in the cobalt mine of Hvöna in Sweden, and is named after Von Kobell.

Kobold. A German word signifying a spirit or spectre, and corresponding to the English *goblin*, of which it is probably the origin. In some parts of Germany there is scarcely a house or a family to which kobolds are not said to be attached; and according to the super-

opening out, &c.; 2. *Right or reef knot*, for securing all lashings where the ends of the rope meet together; 3. *Draw knot*, which offers great facility in undoing; 4. *Running knot*, used to

stitious notions of the peasantry, they prevail over all domestic operations, many of which they perform. The name of the metal *cobalt* is derived from the above.

Kof. A small two-masted vessel, formerly employed in the Dutch fisheries. It had two masts, main and fore, with a large spritsail abaft each. This arrangement enabled her to sail very close to the wind, and she could set squaresails if the wind happened to be astern.

Kokoona (Cing. kukoon). A large forest tree of the order *Hippocrateaceæ*, native of Ceylon. The yellow corky bark is used by the Cinghalese in the preparation of a cephalic snuff; and a lamp oil is expressed from the seeds.

Kola Nut. Kola, Gola, Guro or Goro Nuts are the seeds of the *Cola acuminata*. They are largely used as food and medicine by the natives of West Central Africa, and are highly valued, commercially, socially, and even politically. From the researches of Drs. Daniell and Atfield (*Pharmaceutical Journal*, March 1865) it would seem that their virtues must be ascribed to the presence of about two per cent. of *theine*, a substance existing also in tea, coffee, guarana, and maté, from one or other of which, beverages are prepared by Europeans, Americans, and Asiatics. Kola, like the substances just mentioned, has long been known to produce sleeplessness when eaten. It is curious and interesting to find that in all quarters of the globe man's instinct has induced him to select for the preparation of beverages, plants which differ greatly in appearance, characters, and habits, but which contain the same active principle.

Kolpodes, Kolpoda (Gr. *κολπῶδης*). The name of a genus of Polygastric Infusories, characterised by their flat and sinuous figure.

Komenic Acid. [COXYENIC ACID.]

Königite. A variety of Brochantite of a transparent emerald or blackish green colour, found at Katherinenburg in Siberia. It was named after König, late keeper of the minerals in the British Museum.

Könleinite. A fossil resin, found in the Brown Coal of Uznach in Switzerland and near Redwitz in Bavaria.

Koran. [ALCORAN.]

Koreite. A hydrous Labradorite, found at Nagyag in Transylvania, and in China. The name Koreite is applied by Dufrenoy to Agalmatolite.

Kosso, Koussou, or Cusso. The *Drayera anthelmintica*, an Abyssinian vermifuge. [BRAYERA.]

Kotschubite. A mineral of a carmine-red colour, discovered in the gold-washings of Karadinsk in the Ural. Named after Von Kotschuby, the Russian mineralogist.

Köttigite. A native arsenate of zinc, containing cobalt and nickel, and a trace of lime, from the Cobalt Mine Daniel, near Schneeberg in Saxony. Named after its discoverer, Köttig.

Koumiss. A vinous liquid, obtained in Tartary by fermenting the whey of mare's milk.

Koupholite (Gr. *κούφος*, *light*, and *λίθος*, *stone*). A species of zeolite or Pehnite from the Pyrenees: it occurs in small rhomboidal plates, with a pearly lustre, and of a yellowish green colour.

Kraal. The Zulu name for a village.

Kraken (Ger.). A name applied to a fabulous marine monster of gigantic size.

Krameria (after the Kramers, German botanists). An anomalous genus, allied on the one hand to *Leguminosæ*, and on the other to *Polygalaceæ*, with which latter it is most frequently associated, or made a distinct family under the name of *Krameriaceæ*. They are branching undershrubs, with simple or trifoliate leaves, and racemose flowers. *K. triandra*, one of the simple-leaved species, is thought to have yielded the Rhatany roots formerly obtained from Peru, though all the species have probably similar astrigent properties. Mr. Hanbury has recently shown (*Pharm. Journ.* 2 ser. vi. 461) that a very excellent form of Rhatany known as *Savanella Rhatany*, which has to a great extent superseded the former, and which is imported from New Grenada, is produced by a variety of *K. Izina* to which the name of *granatensis* has been given. Rhatany is considered as a useful astrigent medicine.

Krameric Acid. An acid obtained from the root of the *Krameria triandra*, or rhatany.

Krantzite. A fossil resin, occurring in the Brown Coal of Lattorf near Bernsburg. Named after Dr. Krantz of Bonn.

Kraut, Sour. [SAUER KRAUT.]

Kreasote (a word coined from Gr. *κρέας*, *flesh*, and *σώω*, *I preserve*). Kreasote seems to be the principal source of the peculiar odour and of the antiseptic and preservative qualities of wood-smoke. When properly purified, it is a colourless oily-looking liquid of great refractive and dispersive power, of a penetrating smoky odour and a burning taste: its sp. gr. is about 1.04; it remains fluid at 17°; it burns with a sooty flame; is sparingly soluble in water, and is neutral to test paper. It dissolves readily in alcohol, ether, benzole, and acetic acid; and forms a crystalline compound with potash. It coagulates albumen; and a solution of it, containing not more than 1 per cent., preserves meat from putrefaction. The efficacy of crude pyroligneous acid as a preservative of provisions, and the peculiar smoky flavour which it confers upon them, appear to be due to kreasote. It is an irritant poison when undiluted, but when largely diluted it has been found effectual in checking vomiting, and as an application in toothache for the destruction of the nerve. It appears to be closely related to phenic (carbolic) acid, and the formula $C_{16}H_{16}O_2$ has been assigned to it.

Kreatine (Gr. *κρέας*, *flesh*). A crystallisable organic substance contained in the juice of the muscular flesh of animals. The term *kreatinine* has been applied to a product of its decomposition. Kreatine is represented as $C_8H_{10}O_4N_2 + HO$, and kreatinine as $C_8H_9O_4N_3$.

KREITTONITE

Kreittonite. A black variety of Automolite (Zinc-Spinel) found at Bodenmais in Bavaria.

Kromersite. A native chloride of potassium allied to Sylvine, and met with in ruby-red octahedrons at Vesuvius. Named after Kromers, by whom it was analysed.

Kromnits White. A pure variety of *White Lead*, or Carbonate of Lead. [WHITE LEAD.]

Krishna. In Hindu Mythology, a divine being, produced from one of the hairs of Vishnu, and in his turn producing Brahma or Rudra the destroyer. (Muir, *Sanskrit Texts*, ch. ii. sec. 5; Godfrey Higgins, *Anacalypsis*.)

Krisuvigite. A variety of Brochantite, found at Krisuvig in Iceland.

Krokidolite. [CROCIDOLITE.]

Kronos. [ZEUS.]

Krum Horn. An old musical instrument, resembling a cornet. The name has been corrupted by organ-builders into that of the *cremona* stop of the organ.

Kryolite. [CRYOLITE.]

Krystalline (Gr. *κρύσταλλος*, *clear ice*, *crystal*). A term applied by Unverdorben to a salifiable base which forms crystallisable compounds with the acids, and which he obtained from animal empyreumatic oil. [ANILINE.]

Kshatriya or Oshatriya. [CASTE.]

Kufic. An epithet given to the ancient Arabic characters; from Kufa, a town on the Euphrates.

Kühnite. A native arsenate of lime and magnesia found in dirty-white or honey-yellow masses with a waxy lustre, at Longbanshyttan in Sweden. Named after Kühn, by whom it was analysed.

Kumbekephalic (a word coined from the Gr. *κύβη*, a bowl, and *κεφαλή*, the head). Some of the early long-headed or dolichocephalic inhabitants of Scotland had a peculiar lengthened skull, in which the occipital bones were slightly elevated, whilst a depression extended along the parietals. This configuration has received the name *kumbekephalic* from Prof. Wilson. Many skulls of existing races exhibit this character.

Kunkur. A very peculiar deposit widely spread over the peninsula of India, and apparently corresponding in age and in the circumstances of its accumulation with the *drift* of England. It is a compact nodular calcareous clay with many concretions and very few fossils. It is found at all levels up to 3,000 feet above the sea. It is not generally stratified, and varies a good deal in different localities. In composition it is chiefly calcareous, containing about 70 per cent. of carbonate of lime, 15 per cent. of silica, and nearly 20 per cent. of alumina.

Kupaphrite (Lat. *cuprum*, *copper*, and Gr. *ἀφρός*, *froth*). Copper Froth. [TYROLITE.]

Kupfer Diaspore or Copper Diaspore. A variety of Phosphocalcite, with half an equi-

KYROSITE

valent less water, the composition being, according to the following analysis by Kühn:—

Phosphoric acid	24.13
Oxide of copper	69.61
Water or loss	6.20
	99.94

Kupfer Nickel. A term applied by the German miners to a native alloy of nickel and arsenic.

Kupfer Schiefer (Ger.). A series of schistose beds, often bituminous and very fossiliferous, lying near the base of the magnesian limestone or Permian series of deposits in Germany. The beds thus named are worked at Mansfeld in Thuringia for a singular deposit of argentiferous copper, which is mixed up mechanically with the shale and sand, forming a small percentage of the rock. The beds have long been worked, and are not unimportant in an economic sense.

Kupferblende or Copper Blende. Tennantite, with part of the iron replaced by zinc; from near Freiberg in Saxony.

Kupferblüthe. [CHALCOTRICHITE.]

Kupferpecherz. An impure variety of Chrysocola, containing a large amount of Brown Iron-ore, found at Tourinsk in the Ural, and at the Basin of Mines in Nova Scotia.

Kurrajong. A native Australian name for several fibre-yielding plants, as *Hibiscus heterophyllus*, *Plagianthus soides*, *Commersonia platyphylla*, &c.

Kuteera or Kutera. A kind of gum obtained from *Cochlospermum Gossypium*.

Kyanise (named after Kyan, the inventor of the process). A mode of preserving timber from decay, by charging it with a solution of corrosive sublimate. [DAR ROT.]

Kyanite (Gr. *κυανός*, *dark blue*). A blue silicate of alumina, occurring massive and in prismatic crystals. It is the *Disthene* of Häuy, and the *Sappare* of some mineralogists. [CYANITE.]

Kymatin. A variety of Asbestos found at Kuhnisdorff in Saxony.

Kypholite (Gr. *κυφός*, *bent*, and *λίθος*, a stone). A variety of Serpentine.

Kyriological (Gr. *κυριολογικός*, *describing literally*). A term applied by Warburton, in his *Divine Legation* (book ii. s. 4), to that class of Egyptian hieroglyphics in which a part is conventionally put to represent a whole—e.g. a pair of armed hands for a battle, a scaling ladder for a siege, &c.; distinguished from the *tropical*, in which visible objects are used as emblems, or figuratively. [HIEROGLYPHICS.]

Kyrosite. A variety of White Iron Pyrites or Marcasite, containing arsenic and copper, which is found at the Briccius Mine, near Annaberg in Saxony, and also in Chili.

L

The first of the letters, in the English and most other alphabets, called *liquids* or *semi-vowels*, because, like vowels, they can be pronounced for any length of time, which is not the case with the consonants called *mutes*, as *p*, *d*, &c. It is the same as the Greek lambda, and the Hebrew or Phœnician lamed, and is found in the languages of almost all nations, excepting those of some Brazilian and Japanese tribes. In the ancient Greek, Hebrew, Phœnician, Celtic and Latin languages, and in those derived from them, the letter *L* consists invariably of two strokes, though in every possible shape and combination. Thus, in the most ancient Greek alphabets it is written $\Lambda \vee \Lambda$, in the Celtic $< \vee$, in Hebrew ל , and in Latin *L*. *L*, as an abbreviation, stands for *Lucius*, *LL.D.* Doctor of Laws, and *LL.S.* for a sesterium. As a numeral, *L* represented among the ancients, as at present, the number 50, according to the line—

Quinques L denos numero designat habendos.

La. In Music, the syllable by which Guido denoted the last sound in the hexachord. It is now used by the French as synonymous with our note *A*.

Labadists. A sect of religious enthusiasts in the seventeenth century; so called from Jean Labadie, a native of France domiciled in Holland, who was deposed from his preacher-ship by the synod of Dort. They endeavoured to introduce among Protestants similar notions to those of the *Quierists* in the Roman Catholic church, and were accused of similar perversities in practice. [*QUIETISTS.*]

Labarraque's Disinfecting Liquid. A solution of carbonate of soda impregnated with chlorine.

Labarum. The standard of Constantine, which he caused to be formed in commemoration of the alleged vision of the cross in the heavens. It is described as a long pike surmounted by a golden crown inclosing a monogram which contains the first two letters of the name of Christ, and is at the same time a representation of the figure of the cross. Ancient monuments exhibit the figure under two forms, ρ or ρ (sc. χ , ρ). The silken banner which depended from it was embroidered with the figure of Constantine and his family. The labarum is engraved on some of his medals with the famous inscription,

EN TOTTOI NIKA;

and it was preserved for a considerable time, and brought forward at the head of the imperial armies on important occasions, as the palladium or safeguard of the empire. The origin of the word is still undecided. (Beugnot, *Hist. de la Destruction du Paganisme en Occident* i. 57; Milman, *Hist. of Christianity* ii. 152.)

Labdanum. The resin of the *Cistus creticus* and some allied species. [*LADANUM.*]

Label or **Labellum** (Lat. dim. of labium, *a lip*). The third of the inner petals of an orchid, usually quite unlike the others in form, and turned towards the lower side of the flower. The name is also applied to a similar petal in other flowers.

LABEL. In Heraldry, a figure used chiefly by way of distinction or difference in the coat-armour of an eldest son during the life of the father. In this case it has three points; five points when borne by the heir-presumptive of a grandfather living, and so forth.

Labials (Lat. labium, *a lip*). The letters *B*, *P*, *V*, *F*, *M*, are so called, on account of the organ chiefly employed in their pronunciation.

Labiates (Lat. labium, *a lip*). A natural order of monopetalous Exogenous plants of Lindley's Echio alliance, consisting of many hundred species, inhabiting the more temperate regions of the earth. A two-lipped monopetalous corolla, an irregular number of stamens, and a four-lobed ovary, are the essential marks by which it is known from all others. The species are generally herbaceous, with square stems; a small number only consists of shrubs. The flowers are of all colours, but pure blue is uncommon in the order. Many of the species are valued for their fragrance, as *Lavender* and *Thyme*; others for their stimulating qualities, as *Mint* and *Peppermint*; some as aromatics, as *Sage*, *Basil*, and *Marjoram*; while a few are regarded as febrifuges. Numerous species are objects of great beauty, on which account the order is well known in gardens. Among the most ornamental are various kinds of *Salvia*, *Gardoquia*, *Draccephalum*, &c. The order has sometimes been called *Lamiaceæ*, from *Lamium*, one of the genera.

Labium (Lat. *a lip*). In Entomology, a movable organ, often biarticulate, which, terminating the face anteriorly, covers the mouth from beneath, and represents the under lip. [*LADRUM.*]

Lablab (the Arabic name of the *Convolvulus*). A genus of *Leguminosæ* yielding some of the kinds of tropical pulse. *L. vulgaris* and *cultratus* are much cultivated, the young pods being used like kidney beans, while the seeds or pulse are both wholesome and nutritious. Some varieties are better flavoured than others. The pods are flat, and marked along the edges with rough wart-like tubercles.

Labour (Lat. labor). In Political Economy every exertion, muscular or nervous, which is undertaken not for its own sake, but for some purpose of ulterior advantage, and with a view to its appraisement by some measure of value. Many occupations may be

LABOUR

very exhausting, and involve much physical or mental exertion; but if they are satisfied in themselves, and reflect solely on some immediate end, they have no direct economical significance. The labour of an amateur in a game of cricket may be very great, but it has no economical meaning; that of a professional cricketer, who is paid for his time and skill, has a meaning, because it has a market value. The toil of purely scientific observation may be great and unremitting, its results may be of signal benefit to mankind, but it is not economically appraised. But if the same labour is devoted to such ends as are susceptible of pecuniary compensation or material advantage to the student or observer, they fall within the definition of labour. Nor is it necessary, as some economists have suggested, that the exertion should be repulsive, disagreeable, or compulsory. It is quite possible that economical labour may be as agreeable to the worker, as any satisfaction felt in the mere pursuit of pleasure. It is conceivable that advantage and enjoyment should coexist in most occupations. For instance, the discovery of agricultural improvements, in the use of new manures, in the adaptation of machinery, in the trial of new seeds, and in crossing of seeds, may give as much pleasure as profit to the experimenter. The limitation often put upon labour, to the effect that it should be more or less disagreeable, is not an economical, but an ethical consideration, and one that is of by no means universal application.

The expression *unproductive labour* is also ambiguous and misleading, even though it has been sanctioned by the high authority of Adam Smith and many of his successors. It may be used of society collectively; it may apply to the result of individual exertion, and have a primary reference to the satisfaction of an individual's work. In relation to society, its significance is exceedingly vague, unless we are to consider that labour only as productive which is relative to the production of the lowest necessities of life, and to no means of comfort, enjoyment, or elegance. If, however, we may say that human exertions are stimulated by the desire of procuring the largest amount of advantage by the least possible expenditure of force, and that such an impulse is the key to all economical progress, it would be idle to exclude from the class of productive labourers any whose avocations are not degrading, vicious, mischievous, or criminal. Nor is it likely, unless any artificial regulations of society favour particular classes or particular interests, that such callings as those which minister to what are called luxury or enjoyment will ever be excessive or dangerous. All distinct enactments or privileges hindering the distribution of wealth have indeed a tendency towards developing these kinds of occupation which are relative to exaggerated and extravagant expenditure, but they also cripple the just progress of society, and often call into existence classes of persons whose business is to supply those very vicious and mischievous tastes which are ruinous to the individuals in whose favour the pri-

vilage was created. But labour may be unproductive to the individual, i.e. he may fail to secure the advantage which he has proposed to himself, and he may have wasted his capital and exertion. Errors as to the market or saleable value of any commodity or service are no doubt of frequent occurrence, and often entail much individual loss; but in a state of progressive wealth they are far counterbalanced by labour which has achieved its purpose, and which adds to individual advantage and collective prosperity.

Economists, too, have been apt to give an artificial limitation to the word *labour*, by confining it to such exertions as are almost or nearly mechanical. But the term *labour* is as fully applicable to the services of a statesman as it is to the functions of a ploughman or a spinner, and both in the main are as much undertaken for the sake of prospective remuneration. On this point Adam Smith is abundantly distinct. Dividing as he does the distribution of the gross product of labour into wages, profit, and rent, he continually shows that wages are disguised under the name of *profit*, and implies that by profit he intends to mean only that remuneration of capital which is relative to and fixed by the current interest on advances. It is true that the term *wages* is generally limited to that method of payment in which the capitalist remunerates a portion of the labour expended on the article in which he trades; but the distinction between wages and that portion of his profits which he appropriates as the reward of his own energies, skill, and superintendence, is merely an error of popular language, and one which, if uncorrected, tends to serious inconvenience in the interpretation of various social and fiscal expedients. It is hardly necessary to say, that by far the largest portion of national income is the product of labour, and that this product is continually increased by the substitution of mechanical forces for the mere muscular labour of man. It is also clear that the margin on which taxation can operate can be that only which is beyond the necessary subsistence of the labourer, his security against ordinary contingencies, and what is needed for the replacement of capital.

Labour is, economically speaking, set in motion by capital; in other words, the labour must be called into existence, and supplied with the means of subsistence during the time in which production goes on, and up to the period at which the produce of labour is exchanged. Hence, however abundant labour may be, and however urgent the demand for the produce of labour, no product will be forthcoming unless capital be supplied by which labour may be set in motion. The excessive demand for cotton wool which has characterised the cotton manufacture during the last four years has only been very partially supplied. The area over which cotton can be cultivated contains, perhaps, a wider geographical range than the limits assigned to any other botanical production, and the labour available for its culture is amply

LABOUR RENTS

sufficient for a quantity far in excess of any demand hitherto existent. The crop, too, is in several species of cotton derived from an annual. But, as is well known, the manufacture of cotton goods has been almost paralysed by a sudden deficiency in the customary supply. The reason, however, why the demand has not been satisfied, is due to the fact, that the capital necessary to stimulate the labour has been wanting. [PROFIT; MANUFACTURE; TRADES' UNION; WAGES.]

Labour Rents. In the rudest states of society, as in the most civilised, the wealthier and the more influential classes are sustained by the possession of land, a portion of the produce of which they secure to themselves by the fact of appropriation, and by allowing the privilege of labour upon the surface to the cultivator of the soil. When capital is scanty and the union of society feeble, the lord of the soil has been accustomed, in all those parts of the world in which agricultural pursuits prevail, to grant portions of the land which he possesses, to be held either on permanent or precarious tenure by his dependants, on the condition that they contribute a portion of their labour to cultivating that which he retains. Such was the tenure of villenage in England, during the prevalence of the feudal system, a tenure gradually extinguished, or rather substituted by copyholds, in consequence of the gradual exchange of predial services for fixed money payments. [MANOR.] Such was till lately the serf system in Russia; such is practically the ryot system in many parts of British India.

Labour rents were in their first institution a necessary process for the maintenance of an upper or governing class. In England it is not too much to say that in very early times labour rents, or pecuniary compensations in the place of such rents, formed the chief revenues of the feudal barons. But it will be obvious that they are never satisfactory. The labour which is compulsory can never be heartily given, and will always be wasteful and dear. Hence a reform in such a tenure is inevitable, when a community makes any notable advance in civilisation and wealth. There can be little doubt that one of the chief causes which contributed to the great political influence of this country in the middle ages, is to be found in the fact of its having been early able to commute labour rents for fixed money payments, and so to secure a free and improving body of yeomen.

Labourers, Statutes of. Towards the close of the first half of the fourteenth century, a plague of novel and excessive virulence sprang up in the farthest recesses of Eastern Asia. It appears to have travelled very slowly towards Europe; for if the chronological statements of the age can be depended on, it took nearly ten years for this visitation to pass from China to Western Europe. When it did reach Europe, its ravages were fearful. After every allowance being made for exaggeration, seems

LABRADOR FELSPAR

difficult to doubt that it destroyed nearly half the inhabitants. Called at first the Black Death, it has survived as an endemic to our own times under the name of the Turkey, Levant, or Egyptian plague. It forms the background to Boccaccio's *Decameron*, and it is said that, like that of the Athenian plague, its incidence was accompanied by an excessive licentiousness and depravity of manners. The last notable visit of this pestilence to this country occurred in the great plague of London. Its ravages, though not confined to the lower orders, were nevertheless most destructive among the poor; and this for the very obvious reason, that sanitary conditions were wholly unknown to our forefathers, and that the quarantine regulations of the time, under a show of precaution, in reality secured hotbeds for the preservation and spread of infection.

It has been observed, that there is reason to believe the statement that half the working population was destroyed. The immediate effect of the plague was that the rate of wages was, on the whole, doubled in consequence of the scarcity of hands. For instance, while the rate of threshing wheat had stood on an average at 5d. the quarter, it instantly rose to 10d. or 1s., and similarly with other piecework. Day-work also, and all materials, the value of which depends largely upon the labour expended in producing them, as iron and cloth, rose in proportionate rates: the profit on agricultural operations, a considerable portion of the landholder's estate being at that time cultivated for him by a bailiff, fell to a minimum, and the owners of land were threatened with a very large deduction from their customary incomes. The time also, that of the wars between England and France, was one of heavy taxation on personal property, and of continual military service. Hence the aid of parliament was invoked, in order to fix the rate of wages; and the first statute regulating the price of labour was enacted in 1350. The statute fixing the rate of wages was accompanied by others limiting the price of the necessaries of life. Both enactments were absurd, but the latter in a much higher degree than the former. From this time forward, the legislature has attempted to regulate, in various ways, the prices of labour; in earlier times by fixing the rate in parliament, in later by ordaining that the justices of peace in the several counties should meet and determine wages for each current year. Coordinate with these limitations were those which provided against the combinations of labourers, with a view to increase the rate of wages. All these laws were finally repealed in 1826, but they have left a heritage in the reactionary remedy of trades' unions.

Labrador Felspar. Labradorite. A variety of Felspar originally brought from the coast of Labrador. When viewed in certain directions it exhibits a beautiful play of colours; and the mutable opalescent tints of blue, red, green and yellow, which are reflected from the

surface, vary according to the position in which the stone is viewed, so that the same spot exhibits various tints if held in different positions, violet and red being the most rare. It takes a fine polish, and when cut into thin slabs it is employed in jewellery and for other ornamental purposes.

Labrax. A genus of Percoid fishes, dismembered by Cuvier from the Linnæan *Perca* on account of certain modifications of the gill-covers and tongue; the differences being that the opercula of the *Labrax* terminates in two spines, and the tongue, instead of being smooth, is roughened with many minute teeth.

Labridans, Labridæ, or Labroides. The Bream tribe. A family of Acanthopterygii, having the genus *Labrus* as the type. The fishes of this family may be recognised by their oblong scaly body; a single dorsal fin, supported in front by spines, each of which is generally furnished with membranous appendages. The jaws are covered with fleshy lips, and the pharyngeal bones are armed with numerous and strong teeth, disposed like a pavement. [BREAM.]

Labrum (Lat.). In Entomology, the usually movable part which, terminating the face anteriorly, covers the mouth from above, and represents the upper lip. [LABIUM.]

Labrus (Lat.). A genus of spiny-finned fishes in the system of Cuvier, with well developed double fleshy lips. The fishes of this genus are termed *bream*; and are further characterised by their conical maxillary teeth, of which the middle and anterior are the longest, and by their cylindrical and obtuse pharyngeal teeth, which are arranged like a pavement—the upper ones on two large plates, the lower ones on a single one, which correspond with the two others.

Laburnum. The common name of an ornamental early-flowering tree of the Leguminous order, the *Cytisus Laburnum* of botanists. Every part of this common ornamental tree is poisonous, especially the bark and seeds. A curious case of poisoning by it is reported by Dr. Christison in the *Edinburgh Medical Journal* for October 1843, and Dr. Taylor (*On Poisons*) has cited several others. The symptoms are vomiting, purging, and prostration. The term *Cytisin* has been applied to the poisonous principle.

Labyrinth (Gr. λαβύρινθος). Literally, a place, usually subterraneous, full of inextricable windings. Ancient mythology and history give an account of four celebrated labyrinths; the Cretan, Egyptian, Lemnian, and Etruscan. The first, wholly mythical, is said to have been built by Dedalus at the instigation of Minos, to secure the Minotaur. The second, said to have been constructed by Psammeticus, king of Egypt, was built on the isle of Meroë, and was a vast edifice, composed of twelve palaces, all contained within the compass of one wall, and communicating with each other. It had only one entrance; but the innumerable turnings and windings of the terraces and rooms of

which it consisted, rendered it, it is said, impossible for those who had once entered within its walls to get out without a guide. It is supposed to have been designed either as a burial-place for the Egyptian kings, or for the preservation of the sacred crocodiles, the chief objects of Egyptian idolatry. It was partly demolished between the reigns of Augustus and Titus; but even at the period of Pliny's visit, its ruins were magnificent. (Pliny, lib. xxxv.) Pococke's *History of the East*, vol. i. p. 61 &c., and Perry's *View of the Levant*, p. 381, contain a plan and description of the modern state of this labyrinth. There is no evidence of any such building in Crete; the existence of intricate caverns may possibly account for the myth. The labyrinth of Porsenna, as described by Varro, is clearly fictitious.

Labyrinth. A term applied by anatomists to certain internal parts of the ear, from the intricacy of their winding passages. [EAR.]

Labyrinth. In Metallurgy, a series of troughs attached to a stamping mill, through which a current of water passes for the purpose of washing away the suspended pulverised ore, and subsequently depositing it at different distances, depending upon its state of comminution.

Labyrinthodonts (Gr. λαβύρινθος, and ὀδούς, tooth). An order of fossil reptiles, in which the head was defended, as in the *Ganocephala*, by a continuous casque of externally sculptured and unusually hard and polished osseous plates, including the supplementary *postorbital* and *supratemporal* bones, but leaving a *foramen parietale*. Two occipital condyles; vomer divided and denticulous; two nostrils; vertebral bodies, as well as arches, ossified, biconcave; pleurapophyses of the trunk, long and bent; teeth rendered conical by undulation and side branches of the converging folds of cement, whence the name of the order. This group, which is found in the carboniferous strata (*Baphetes*), is otherwise restricted to the carboniferous period. The genera *Baphetes*, *Labyrinthodon*, *Rhombopholis*, *Mastodonsaurus*, *Trematosaurus*, *Metopias*, *Capitosaurus*, *Zygosaurs*, *Odontosaurus*, and *Xestorhynchias*, belong to this order.

Lac (Lat.; Gr. γάλα, γάλακτος, milk). A resinous substance which in India flows from certain trees, in the form of lucid tears, in consequence of punctures made upon their branches by a small insect, the *Coccus ficus*. The *Ficus indica*, and *F. religiosa*, *Buta frondosa*, *Zizyphus Jujuba*, and according to Dr. Hooker a species of *Celtis*, are amongst these which produce it. Dr. Hooker adds: 'The elaboration of this dye, whether by the same species of insect or by many, from plants so widely different in habit and character, is a very curious fact, since none have red juice.'

The commercial varieties of Lac are: *stick lac*, which is the substance in its natural state, investing the small twigs of the tree; *seed lac*, which is the same, broken off from the twigs, and which when melted and formed into thin cakes con-

LAC

stitutes *shell lac*. These varieties of lac have been examined by Mr. Hatchett (*Phil. Trans.* 1804), with the following results:—

	Stick Lac	Seed Lac	Shell Lac
Resin	68·0	88·5	90·2
Colouring matter.	10·0	2·5	0·5
Wax	6·0	4·5	4·0
Gluten	5·5	2·0	2·8
Foreign bodies .	6·5	—	—
Loss	4·0	2·5	1·8
	100·0	100·0	100·0

The great consumption of lac is in the manufacture of dye stuffs, sealing wax, and of certain varnishes and *laquers*.

LAC. In Commerce, a word used in the East Indies, to denote the sum of 100,000 rupees, or 12,000*l.* sterling. One hundred lacs, or 10,000,000 rupees, make a *crore*.

Lac Dye, Lac Lake. These are two preparations of lac imported in small cubic cakes from the East Indies, and extensively used in the production of scarlet dye. They are said to be prepared by digesting seed lac in an alkaline solution, which produces a deep pink liquid, the colouring matter of which is thrown down in combination with alumina by the addition of a solution of alum. The colouring matter of these dyes much resembles that of cochineal, for which it is largely substituted. In dyeing scarlets the liquid used for dissolving the colour is a solution of tin in hydrochloric acid, and tartar and sumach are used as mordants.

Laccic Acid. A peculiar acid said by Dr. John to exist in some varieties of seed lac. It is yellow, crystallisable; and forms soluble salts with potassa, soda, and lime, and insoluble salts with the oxides of mercury and lead. It occasions no precipitate in solution of baryta or of oxide of silver.

Laccine. A substance discovered in shell lac by Unverdorben. It remains after all the soluble matters in water, alcohol, and ether have been extracted. It is brittle, yellow, translucent; and soluble in caustic potash, and in sulphuric acid.

Lace (Ital. laccio, Lat. laqueus, a *lace* or *noose*). An ornamental fabric of linen or cotton thread, formerly made by hand (when it was called *pillow* or *bone lace*), but of late years produced by machinery, and generally termed *bobbin-net*. 'This manufacture,' says Dr. Ure, 'may be said to surpass every other branch of human industry in the complex ingenuity of its machinery; one of Fisher's spotting frames being as much beyond the most curious chronometer in the multiplicity of mechanical devices, as that is beyond a common roasting jack.'

The costly and complicated machines by means of which bobbin-net is produced are termed *lace frames*. A *rack of lace* is a certain number of meshes counted perpendicularly, and contains 240 meshes or holes; and such has already been the improvement in this manufacture, that the cost of labour in making a *rack*, which was twenty years ago 3*s.* 6*d.*, is

LACISTEMACEÆ

now reduced to 1*d.* Formerly the wholesale price of a 24-rack piece, five quarters broad, was 17*l.* sterling; the same is now sold for 7*s.* In the *Commercial Dictionary* will be found full statistical details of the value of the lace manufacture in this country, together with a learned and curious account of the origin and history of the fabric.

Lace-bark. [*LAGETTA.*]

Lace-leaf. [*OUVIRANDRA.*]

Lacerna (Lat.). A long woollen military cloak, worn at first only by the Roman soldiers, but which increased so much in fashion that at the period of the triumvirate it became a favourite piece of dress with all the higher classes of Roman citizens, both civil and military, and remained so till the times of the emperors Valentinian and Theodosius, when the senators were prohibited from wearing them in the city. Martial speaks of lacernæ which cost 10,000 sesterces (80*l.*).

Lacerta (Lat.). The *Lizard*; a constellation of the northern hemisphere, near Cepheus and Cassiopeia, formed by Hevelius.

Lacertidæ (Lat. lacerta, a *lizard*). A group of the order *Sauria*, forming the second family in the Cuvierian system, in which the characters are given as follows: Tongue long, slender, extensible, and bifurcate at the extremity, as in the serpent tribe; ear-drum membranous, on a level with the surface of the head or very slightly sunk; eyelids consisting of a production of the skin, with a longitudinal slit, closed by a sphincter, and a rudimental nictitating or third eyelid; body elongated; feet with five toes each; digits separate and unequal, particularly the hind ones, all armed with nails; scales on the belly and round the tail arranged in transverse and parallel bands. Cuvier subdivides the *Lacertidæ* into the two great genera *Monitor* and *Lacerta*, each of which have been again subdivided.

Lachenalia (after De la Chénal). A genus of *Liliaceæ* from the Cape of Good Hope, consisting of bulbous plants, with spotted orchis-like leaves, and spikes of pendulous tubular flowers, often yellow. They are ornamental spring flowers for the greenhouse, but have no useful properties.

Laches (Fr. lache, *negligent*). In Law, slackness or negligence. A term used to signify that degree of negligence which throws on the party committing it the evil consequences resulting to him from it.

Lachesis. [*FATES.*]

Lacing. In Sea language, the rope used to fasten a sail to its yard or gaff; also the piece of timber intervening between the figure-head of a ship and the knee of the head.

Laciniate (Lat. lacinia, a *fringe*). In Botany, having the margin slashed into fringe-like segments.

Lacinula. In Botany, a term given to the abruptly inflexed acumen of each of the petals of an umbelliferous flower.

Lacistemaceæ (Lacistema, one of the genera). A natural order of hypogynous Exogens.

LAONICUM

belonging to the Violal alliance, and distinguished by the amentaceous, scaly, apetalous, polygamous flowers, and unilateral stamens. The order comprises a few shrubs, found in the woods of equinoctial America.

Laconicum. A dry sudorific bath in a chamber heated with warm air by means of a stove. It was so called by the Romans as having been first introduced in Laconia.

Laconism. A short and pointed saying; so termed from the celebrity which the Lacedæmonians enjoyed for their brief and sententious mode of expressing themselves. There is an essay by Puteanus, *De Laconismo*.

Lacquer. A varnish, consisting of a solution of shell lac in alcohol, coloured by gamboge, saffron, annatto, or other yellow, orange, or red colouring matters. Lacquers are chiefly used for varnishing brass and some other metals, in order to give them a golden colour and preserve their lustre. The term *lacquer* is also applied to a mixture of Swedish pitch and coal tar, with which the inside of certain shells for rifled guns is coated, in order to prevent excessive friction between their interior surface and the bursting charge of powder during flight.

Lacrymal (Lat. *lacryma*, a tear). Relating to tears; as the *lacrymal glands*, by which they are secreted. They are placed in a depression of the frontal bone, above the external angle of the eye; the tears pass from them to the eye by the lacrymal ducts, which are six or eight in number.

Lacrymatory. A small vessel of glass or earthenware, which it was customary at Roman funerals to fill with the tears (*lacrymæ*) of the mourners, and deposit them with the ashes of the deceased in the sepulchre.

Lacteals (Lat. *lac*, milk). The absorbents of the mesentery, which convey the milky fluid called *chyle* from the small intestines to the thoracic ducts.

Lactic Acid. The acid of sour milk. It is formed in a variety of processes, and is a frequent product of the acidification of vegetable substances. It is best obtained by dissolving 8 parts of cane-sugar in 50 of water, to which one part of casein or of poor cheese and three parts of chalk are added. This mixture kept for two or three weeks at a temperature of 80° gradually forms crystals of lactate of lime, which after having been purified by recrystallisation may be decomposed by sulphuric acid. The residue digested in alcohol leaves sulphate of lime, and gives an alcoholic solution of lactic acid.

Pure lactic acid is an uncrystallisable liquid of a sharp acid taste, soluble in alcohol and in ether, and represented by the formula $C_{12}H_{10}O_{10} \cdot 2HO$. By long exposure to a heat of 265°, it becomes anhydrous ($=C_{12}H_{10}O_{10}$), and in that state is nearly insoluble in cold water; but when boiled in water, it gradually reverts to the hydrated state.

Lactic acid is contained in the fluids of the muscular tissues, and occasionally in some of the excretions.

LACTUCARIUM

Lactime, Lactose. *Sugar of milk.* This important form of sugar is exclusively of animal origin, and is contained in the milk of the mammalia: it is secreted in greatest abundance by the herbivora, but also by the carnivora, though fed upon animal substances only. It is largely prepared in Switzerland, by the evaporation of whey, and crystallises upon sticks immersed in the concentrated liquid; it forms mammillated masses composed of four-sided prisms. Sugar of milk is white, sweetish, and gritty between the teeth; it requires about six parts of water for solution, and is insoluble in alcohol and in ether. When boiled in very dilute acids it slowly passes into glucose. Under the influence of caseine, which acts as a ferment, sugar of milk undergoes alcoholic fermentation; but in the spontaneous souring of milk, lactic acid is formed. Like the other sugars, lactine is a hydrate of carbon, represented by $C_{24}H_{24}O_{24}$. According to Regnault, in combining with oxide of lead it loses five atoms of water, so that the formula $C_{24}H_{16}O_{16} + 5HO$ has been adopted. The homœopaths use sugar of milk as a vehicle for their remedies, objecting to common sugar on account of the traces of lime which it contains.

Lactometer (Lat. *lac*, and *metrum*, a measure). A term applied to a glass tube for ascertaining the proportion which the cream bears to the milk of any particular cow, or of the produce of a whole dairy. The tube is about half an inch in diameter, and a foot in height, with a graduated scale marked on the outside. It is filled with milk when newly drawn from the cow, and as it cools the cream rises to the surface, and the proportion which it bears to the milk is ascertained by counting the degrees opposite to each. Various other *lactometers* have been suggested, but none of them satisfactory in reference to the easy determination of the absolute quantity of cream (or butter) contained in various samples of milk.

Lactone. A pungent volatile liquid occurring among the products of the destructive distillation of lactic acid.

Lactuca (Lat. from *lac*, milk). To this genus of the Cichoraceous group of *Compositæ* belong the esculent *L. sativa* and the medicinal *L. vitrosa*. The former, which is the Garden Lettuce, is well known as one of the most agreeable and useful of salad plants. The narcotic and sedative principles which exist in lettuces do not occur except to an infinitesimal extent in the succulent young leaves that form salad; but when the flowering stem is thrown up, the sap becomes milky and bitter, and its narcotic properties are then more fully developed. The sedative effects of lettuce appeared to have been known from the earliest times. The popular opinion respecting the properties of these plants is maintained in our own times by the doggel—

for want of rest,
Lettuce and cowslip-wine *probatum est*.

Lactucarium. The inspissated milky juice of the *Lactuca sativa*, or common Garden Let-

LACTUCIC ACID

tuce. It possesses slight anodyne properties, and is sometimes used as a substitute for opium.

Lactucic Acid. A peculiar acid, discovered by Pfaff in the juice of the *Lactuca virosa*. It bears some resemblance to oxalic acid; but differs from it in giving a green precipitate with the protosalts of iron, and a brown precipitate with sulphate of copper.

Lactucin. A bitter crystalline resin; the active principle of the wild Lettuce.

Lacuna (Lat.). In Botany, a term applied in describing lichens, to denote one of the small hollows or pits on the upper surface of the thallus. Also a name given occasionally to the internal organ, commonly called an air-cell, lying in the midst of the cellular tissue of plants.

Lacunar (Lat.). In Architecture, the ceiling, or the underside of the member of an order. Also the under side of the larmier or the corona of a cornice. The under side also of that part of the architrave between the capitals of the columns. The ceiling of any part in architecture receives the name of lacunar only when it consists of compartments sunk, or hollowed, without spaces, or bands between the panels; if it be with bands, it is called a *laquear*.

Lacunose (Lat. *lacunosus*, from *lacuna*, a pit or cavity). In Zoology, when a surface has a few scattered, irregular, broadish, but shallow excavations.

Lacustrine Deposits. By this name the geologist means such deposits as have evidently been formed at the bottom of pools of fresh water. The deposits of lakes differ from those of rivers, not merely in the fact that they are of finer material and slower accumulation, but that from the nature of the case there is a greater amount of chemical change connected with them, owing to the more regular and equable condition under which they have been formed. In large lakes there is generally at one part a delta of coarse rolled blocks and gravel where some river enters, but the floor of the lake is elsewhere coated with fine mud, slowly accumulating, and not unfrequently the floor is much influenced by organic causes, or by substances separated from chemical solution in the water; of the latter kind are deposits of salt, gypsum, and other minerals from the waters of salt lakes. Most of the well-known lake deposits are of tertiary date, but some older deposits of limestone near the coal measures and some marls may also be regarded as lacustrine. It not unfrequently happens that the ancient borders of lakes, known only by lacustrine deposits, may be traced with tolerable certainty in mountain districts. Marls are very common deposits in lakes, but the order of arrangement of the rocks is often very irregular. [AQUEOUS ROCKS AND FRESHWATER DEPOSITS.]

Lacustrine Habitations. Under this name are described remains of human habitations of extreme antiquity, constructed by former inhabitants of Europe on certain lakes in Switzerland, Ireland, and elsewhere, and only recently brought into notice by archaeologists and geologists.

LADY

The habitations in question formed villages, constructed entirely on piles in the waters of the lakes, and communicating with the shore by causeways or bridges, and also on piles which were often of great length. They were thus entirely safe from land attack. In most cases they have been destroyed by burning, and the charred piles are the best indications of the position of the villages. In the water amongst these piles has been found a rich variety of almost every kind of material used by the inhabitants. Fishing implements, fragments of boats, and various articles in stone and metal, might have been expected; but there are also remains of perishable objects, such as cloth, and even of loaves of bread reduced to cinder.

It is certain, from the evidence thus afforded, that there existed in various parts of Central and Western Europe races of men who had attained a certain degree of civilisation at a date long anterior to the most ancient local records. Who these were, whence they were derived, and how and when they became extinct, are problems yet unsolved. They preceded the existing races, but succeeded other peoples of whom we have records in the caves of England, France, and Belgium, and in the shell-heaps or *kitchen-middens* (Dan. *kjökken-mødding*) of the shores of Scandinavia and Scotland.

Ladanum (Lat.; Gr. *λδανον* or *λδανον*). A resin which exudes from the *Cistus creticus*, a shrub which grows, as its name implies, in Crete. In the time of Dioscorides it was collected by combing the beards of the goats which browse on the plants.

Ladder (A.-Sax. *hlædre*). The framing used in scaffolding to mount from one stage to another. Ladders are usually made of a tree split down the middle: the two halves are then placed about one foot apart, and are kept in their position by the *rounds* or *rings* which form the foothold; they are placed about one foot from centre to centre. In mines, the sides are made occasionally of wrought timbers, but sometimes of wrought iron.

LADDER. On Shipboard, a set of wooden steps affording access between the several decks. There are several in a large ship, distinguished in name by their purpose or by the part of the vessel in which they are situated; that leading down from the quarter-deck is the *companion ladder*; *accommodation ladder* is a temporary flight of steps placed against the outside planking of a ship to furnish an easy entrance from boats. *Ladder-ways* are the square openings cut in the decks for the insertion of the ladders.

Ladies' Slating. A size of slates, 16 inches long by 8 inches wide; 222 such slates are needed to cover one square of roofing.

Lady (A.-Sax. *hlæfdige*). This title properly belongs to the daughters of all peers above the rank of a viscount; and is extended, by courtesy, to the wives of knights of every degree. (For the origin of the word, see Max Müller, *Lectures on Language*, second series, p. 255.)

LADY-DAY

Lady-day. In the Calendar, the 25th of March, being the Annunciation of the Virgin Mary. It is one of the immovable festivals of the church, having relation to Christmas, or the day of the nativity of Christ, which it precedes by nine months.

Læmodipods (Gr. *λαμός*, *throat*; *πούς*, *foot*). The name of an order of Crustaceans, in which the head is confluent with the first segment of the thorax, and supports the four anterior feet. The *Læmodipods* are the only Malacostracans with sessile eyes, and in which the posterior extremity of the body exhibits no distinct branchiæ. The females carry their ova beneath the second and third segments of the body in a pouch formed of approximated scales. All the species are marine.

Læstrygones (Gr. *λαϊστρυγόνες*). In the Homeric Mythology, certain gigantic beings, represented as keepers of sheep, on the confines of day and night, and ruled by a king named Antiphates. (*Odyssey* x. 83.) [CYCLOPES; PHÆACIANS.]

Lævoracemic Acid. Racemic acid is a compound of two acids of the same composition, but having opposite effects on a ray of polarised light. One of these acids twists the ray to the right, and is hence called *dextroracemic acid*; the ordinary tartaric acid of commerce is this substance. The other twists it to the left, and is therefore termed *lævoracemic acid*.

Lævotartaric Acid. [LÆVORACEMIC ACID.]

Lagan. [FLOTSAM.]

Lagonaria (Lat. *lagena*, *a bottle*). The Bottle or Club-shaped Gourds are names given to varieties of *L. vulgaris*. The genus belongs to the *Cucurbitaceæ*, and consists of annual pubescent herbs, with heart-shaped leaves, white monœcious flowers, and flask-shaped fruit, which when mature become woody pepos. They are found in the warm parts of Asia and Africa.

Lagetta (Lagetto, the native name). The Lace-bark tree of Jamaica is *L. lintearia*, the inner bark of which consists of numerous concentric layers of fibres, interlacing in all directions, and thus having a considerable resemblance to lace. The bark is made into bounnets, collars, and other articles of apparel, and was formerly made into thongs and whips for flogging negroes.

Lagging of the Tides. In Terrestrial Physics, a phenomenon of the tides, consisting in the irregularity of the lengths of the successive tide-days or intervals of the occurrence of high water at any particular place, and caused by the combined action of the sun and moon on the ocean. If the tides were caused by the moon's attraction only, the intervals between two successive arrivals at the same place of the same vertex of the tide-wave would be the lunar day, that is, the interval between two successive arrivals of the moon at the same meridian. In like manner, if the tides were caused by the sun's attraction only, the tide-day would be of the same length as the solar

LAGOTHRIX

day. In consequence of the moon's revolution about the earth in the same direction as the diurnal rotation, the lunar day is longer than the solar; and the actual or lunisolar tide being the result of the superposition of the two tides caused by the sun and moon respectively, it follows that from the time of coincidence of these two tides the actual tide-day (reckoned in mean solar time) will become longer and longer, until the moon has completed a quarter of a revolution, after which the lunar wave will fall back on the next following solar wave, and the tide-day will become shorter and shorter during the next quarter of the moon's revolution, and the coincidence will again take place when a semi-revolution is completed. This alternate acceleration and retardation of the tidal intervals is called the *priming and lagging of the tides*, and is most remarkable about the time of new and full moon. [TIDES.]

Laggings. The planking that forms the actual surface of a centre of an arch, and which is intended to receive the voussoirs. The term is also applied to the covering put round a cylinder of a steam-boiler, in order to prevent the radiation and the consequent waste of heat; the laggings are in these cases of wood, and they enclose a layer of felt or other non-conducting substance.

Lagomys (Gr. *λαγός*, *a hare*; *μῦς*, *a mouse*). The generic name of certain Rodents, called *rat-hares*, now peculiar to Siberia. They differ from the hares proper in having moderate-sized ears, legs nearly equal, clavicles nearly perfect, and no tail. The fossil bones of a species of *Lagomys* have been discovered in the osseous breccia of Corsica and in England.

Lagonite. An earthy mineral of an ochreous yellow colour, found as an incrustation at the lagoons of Tuscany.

Lagoon (Lat. *lacuna*, *a pit or hole*). The name given particularly to those creeks along the coast of the Adriatic, which are formed by water running up in the land. In some places they are deep; but generally they are so shallow as to emit noxious exhalations. They contain many islands; on sixty of which the city of Venice is built. Towards the sea these islets are secured by dams, either natural or artificial.

Lagophthalmia (Gr. *λαγός*, *a hare*, and *ὀφθαλμός*, *an eye*). A disease in which the eye cannot be closed. Sometimes it is a paralytic affection, but sometimes it depends upon enlargement of the eye; it is also occasionally connate. The term has reference to the notion that hares sleep with their eyes open.

Lagopus (Gr. *λαγός*, *a hare*; *πούς*, *a foot*). The generic name of those birds of the grouse tribe which have a round or square tail, and whose toes are feathered as well as the legs.

Lagostoma (Gr. *λαγός*, and *στόμα*, *the mouth*). The harelip.

Lagotherix (Gr. *λαγός*; *θρίξ*, *hair*). A genus of South American or Platyrhine monkeys, characterised by their round head, a thumb on the anterior hand (a characteristic which distinguishes them from *Atelæ*), and the

LAGRANGE'S THEOREM

tail partly naked. The grison, or silver-haired monkey, is a species of this genus.

Lagrange's Theorem. This theorem enables us to develop any function of y in a series according to x , when y is an implicit function of x and z in virtue of the given relation $y = z + x \phi(y)$. It is thus expressed:

$$F(y) = F(z) + F'(z) \cdot \phi(x) \cdot \frac{x}{1} \\ + \frac{d}{dz} \left\{ F'(z) [\phi(x)]^2 \right\} \frac{x^2}{1 \cdot 2} + \&c. \\ + \frac{d^2}{dz^2} \left\{ F'(z) [\phi(x)]^n \right\} \frac{x^n}{1 \cdot 2 \dots n} + \dots$$

This theorem was subsequently generalised by Laplace to embrace the case where

$$y = f[z + x \phi(y)].$$

To obtain Laplace's theorem it is merely necessary to replace, in Lagrange's, z by $f(z)$. Lagrange gave his theorem in the *Mém. de l'Acad. des Sciences* 1768; Laplace gave his in the *Mécanique Céleste*.

Lagrimoso (Ital.). In Music, a direction to the performer, when appended to a piece of music, denoting that it is to be performed in a weeping, plaintive manner.

Laird. A Scottish term, applied, as Libb remarks, to 'a landed gentleman under the degree of a knight;' it is regarded by many philologists as originally equivalent to **Lord**. Anciently the title of *laird* was given only to those proprietors who held immediately of the crown; and this distinction is still preserved in the Highlands. The designation *tiern*, corresponding to *laird* and rendered by it, is given to no one whose property is not worth two or three hundred per annum, while it may be withheld from a man whose rental extends to as many thousands; because the former acknowledges no superior under the king, while the latter does.

Laiety (Gr. λαός, *people*). The great body of the people, as opposed to those who are set apart for the celebration of Divine worship—the clergy. This distinction is plainly observed in the writers of the third century—Origen, Cyprian, and Tertullian. The word *laiety* is properly a general name for the people: in the writings of the Fathers βασιλικοί, *seculars*, ἱερωαί, *private men*, and λαϊκοί, *laymen*, are used indifferently to express this class.

Lake. A compound of alumina with the red colouring matter of certain animal and vegetable substances. Sometimes the term *lake* is indiscriminately applied to all compounds of alumina and colouring matter.

Lake Dwellings. [LACUSTRINE HABITATIONS.]

Lakes (Lat. lacus). Sheets of water occupying depressions on that part of the surface of the earth not covered by the waters of the ocean. Lakes differ from inland seas in not communicating with the ocean except by a river. They differ from pools and ponds not only in being larger, but in having definite banks and permanent limits.

LAMA

Lakes occur at all levels, from that of the Dead Sea, nearly 1,400 feet below the ocean, to that of Titicaca, 1,300 feet above it. Near the former is the Lake of Gennesareth, 700 feet above the Dead Sea, but also 700 feet below the Mediterranean level. The waters of this lake are generally sweet, cool, and refreshing, though several salt springs enter it at various points. The bed is a lower platform of the Jordan valley.

Lakes are for the most part only moderately deep, but there are important exceptions. They vary in dimensions from the small lakes of Scotland or England to Lake Superior with its area of upwards of 40,000 square miles. Although lakes are generally fresh, some are loaded with saline and other foreign minerals to the extent of nearly one-third of their whole contents. In these cases the prevailing material is not common salt, but chiefly chloride of magnesium. Lakes exist in all countries, and even in most parts of them, so that their number is almost infinite; but the principal examples are generally in groups connected with the great drainage systems of the countries in which they occur. The principal groups of lakes in the various large tracts of land are noticed under the names of the different countries in which they are found.

The origin of lake basins in mountain countries has recently been a subject of discussion among geologists. On the one hand, they have been attributed entirely to the eroding power of water and ice, but chiefly to the latter; and on the other hand, to clefts and fissures produced by mechanical violence during the elevation of the mountain chains.

Lake Iron-ore. A Bog iron-ore, found in the northern parts of Finland and in Sweden, in the neighbourhood of reed-banks and on the slopes of the larger and deeper lakes. [BROWN IRON-ORE.]

Lallation (Lat. *lallare*, to sing lullaby). The imperfect pronunciation of the letter *r*, which is made to sound like *l*; hence also the term *lambdacismus*.

Lama. Among the Mongols, a title given to priests in general; among the Calmucks, to the higher classes of priests only. The Dalai-Lama (i. e. Great Lama) is honoured by various tribes of Tartaric descent as the representative of divinity, or rather as a real divinity dwelling on the earth. This personage resides at Lassa in Thibet, and pilgrimages are made to his residence by the inhabitants of many distant regions of Tartary. He is now chiefly dependent, in a political sense, on the Chinese empire. When the actual Dalai-Lama dies, his spirit is supposed to seek another body in which to be born again; and the new Dalai-Lama can only be discovered by a certain favoured class among the priests. The worshippers of the Dalai-Lama also pay peculiar reverence to two other subordinate Lamas (Teeshoo and Taranaut Lama). They are distinguished by the title of *Yellow Caps*: the *Red Caps*, another sect in Tartary, are under three other Lamas,

LAMA

styled the three *Shamonars*. See Huc and Gabet's *Travels in China and Thibet*, an interesting work but perhaps not altogether trustworthy work.

Lama, Llama, or Glama. The name of a species of the camel tribe peculiar to South America. [AUCHENIA.]

Lamantin. The name given by French naturalists to the manatee or sea-cow. [MANATUS.]

Lambdoidal Suture. The union of the parietal with the occipital bones; shaped in man something like the Greek letter Λ or *lambda*.

Lamella (Lat. dim. of *lamina*, a plate of metal). In Botany, the foliaceous erect scales appended to the corolla of many plants, as in *silene*; also the gills forming the hymenium of an agaric, and the plate or thin part found at the end of many styles.

Lamellibranchiata (Lat. *lamella*, and *branchia*, gills). An order of Acephalous Molluscs, comprehending those which have the gills in the form of large semicircular layers disposed symmetrically, two on each side.

Lamellicorns (Lat. *lamella*; cornu, a horn). The sixth and last section of Pentamerous Coleoptera of the system of Latreille, in which the antennæ are inserted into a deep fossula under the lateral margin of the head. These antennæ are always short, usually consisting of nine or ten joints, and always terminated in a club usually composed of the three last, which are lamellar; sometimes flabelliform, or disposed like the leaves of a book, opening and closing in a similar way; sometimes concentrically contorted and fitting into each other, the first or inferior then being semi-infundibuliform and receiving the others; and sometimes arranged perpendicular to the axis, and forming a sort of comb.

The body is generally ovoid or oval, and thick. The exterior side of the two anterior tibiae is dentated; and the joints of the tarsi, with the exception of those of some males, are entire, and without brush or pellet beneath.

The anterior extremity of the head most commonly projects, or is dilated in the manner of an epistome. The mentum is usually large, covers the labrum, or is incorporated with it, and bears the palpi. The mandibles of several are membranous, a character observed in no other Coleopterous insects. The males frequently differ from the females, either by prominences on the thorax or head in the form of horns or tubercles, or by the largeness of their mandibles.

This family is very numerous; and is one of the most beautiful of the order for size of body, and the variety of forms exhibited in the head and thorax, and frequently also for the splendour of the metallic colours which ornament the species feeding on living vegetables. The other species, however, feeding on decomposed vegetable matter, are usually of one black or brown hue. Some of the Coprophagi, however, do not yield even in this respect to the former. They

LAMIDÆ

are all furnished with wings, and their gait is heavy.

The body of the larva is long, almost semicylindrical, soft, frequently rugose, whitish, and divided into twelve annuli, with six squamous feet: the head is squamous, and armed with stout mandibles. Each side of the body is furnished with nine stigmata or breathing pores. Its posterior extremity is thicker, rounded, and almost always doubled under it; so that the back being arcuated or convex, the animal cannot extend itself in a straight line, crawls badly on a level surface, and falls backwards or on its side every instant.

Some of them require three or four years to become pupæ: they construct in their place of residence an ovoid shell, or one resembling an elongated ball, composed of earth or the remains of substances which they have gnawed, and the particles of which are cemented by a glutinous matter produced from their body. Their aliment consists of the dung of various animals, mould, and the roots of vegetables (frequently such as are necessary to man), of which they sometimes destroy immense quantities, to the great loss of the cultivator of the soil.

Lamellirostrals (Lat. *lamella*, and *rostrum*, a beak). A tribe of swimming birds, the fourth in the system of Cuvier, comprehending those in which the margin of the beak is furnished with numerous lamellæ or dental plates, arranged in a regular series, as in the swan, goose, and duck. The birds comprised in this family pass most of their time in the fresh waters. Some come on shore to graze; others feed on aquatic plants, insects, vermes, or small fish, and reptiles, which their long neck enables them to reach or seize with facility. Some of the species dive in quest of their prey, and can remain a considerable time under water. All the Lamellirostrers of Cuvier were comprised in the great genus *Anas* of Linnaeus.

Lamia (Lat. and Gr.). An imaginary being, concerning which many superstitious notions were prevalent among the Greeks and Romans; sometimes represented as a species of monstrous animal, sometimes as a spectre or vampire. The Lamia of Pliny are animals, with the face and head of a woman and the tail of a serpent, inhabiting the deserts of Africa. According to mythologists, the first Lamia was a daughter of Neptune or Belus, who seizes and devours new-born infants in their cradles. In the story of Machates and Philemon (from which Goethe has borrowed his ballad of the *Bride of Corinth*), a young man is represented as marrying a Lamia, or Empusa, who sucks his blood at night. A similar tale occurs in the *Life of Apollonius of Tyana* by Philostratus. The Christian superstition of incubi, and the Oriental belief in vampires, seem to bear marks of the same origin.

Lamiaceæ. [LABIATÆ.]

Lamidæ. The subdivision or family of *Lanina*, in which the sides of the thorax are either smooth and rounded, or tuberculate,

LAMINÆ

rugous, or spiny, but not furnished with movable tubercles or spines.

Laminae. A tribe of Longicorn beetles, distinguished, according to Latreille, by their vertical head; filiform palpi, whose terminal joint is more or less ovoid and tapers to a point; maxillæ with the outer lobe slightly narrowed at the end; antennæ frequently setaceous and simple; and thorax, exclusive of the lateral spines or tubercles, nearly equal throughout. Some species are apterous, a modification which occurs in no other tribe of Longicorn beetles.

Laminae Dorsales (Lat. *lamina*, a plate of metal, and *dorsum*, the back). The two parallel ridges which in the embryo of fishes coalesce and form the neural axis and the rudiments of the *chorda dorsalis*, are termed *laminae dorsales*. The *laminae ventrales* are downward extensions of the same layer, to include the viscera and the nutrient yolk. These latter, when they coalesce below, form the external (serous or tegumentary) layer of the yolk sac.

Laminaria (Lat. *lamina*). A genus of olive-spored *Algae*, the type of the order *Laminariaceae*. Some of the species are of immense size, such as *L. digitata* and *bulbosa*, which with *L. saccharina* are brought away as hygrometers by the visitors to our sea-coasts. They yield an enormous supply of seaweeds for the preparation of manure or kelp, and delight chiefly in the colder seas of the North.

Laminarites. A term applied by Brongniart to a species of fossil fucus found in the secondary strata of Aix, near La Rochelle.

Lamium (Lat.). A genus of *Labiatae* of which several species occur wild in this country, and are commonly called Dead Nettles. They are weeds of hedges and cultivated land.

Lammas Day. In the Calendar, August 1. Dr. Johnson supposes this term to be a corruption of *Lattermath*, which signifies a second mowing of grass. Others derive it from a custom which once prevailed in some parts of England, of bringing a lamb alive on this day into the church at *high mass*. Others again derive it from a Saxon term signifying *loaf-mass*, so named as a feast of thanksgiving for the first fruits of the corn.

Lamp (Gr. *λαμπάς*). The general term for the contrivances used in producing artificial light from the combustion of inflammable liquids. The peculiar applicability of oil to the production of artificial light, which could not fail to be discovered at a very early period, rendered the use of lamps universal among the nations of antiquity. The Egyptians, Hebrews, Greeks, and Romans, vied with each other in the construction of these instruments; and the specimens of some that have been transmitted to our times display much taste and elegance of design. It would seem, however, that they confined themselves to external embellishment; for it is only within the last century that any material improvement was effected in construction.

LAMP

The most simple lamp consists of a vessel containing oil, and having a depression or spout on one side, holding a wick capable of imbibing the oil by capillary attraction. The oil thus raised through the wick, when ignited, is so heated as to be converted into vapour, which vapour, in a state of combustion, constitutes the flame of the lamp. To render air accessible to every part of the flame so as to insure perfect combustion of the oil, is an essential object in modern lamps; and in this respect the texture, materials, form and dimensions of the wick, are matters of much importance. If the wick be too large, the carbon remains unburnt in the interior of the flame, and produces smoke; and if the wick be too small, the light will be deficient. These inconveniences had been long observed, and many attempts made to remedy them; but it was not till the year 1780, when M. Argand invented the burner which bears his name, that lamps came into general domestic use. The principle on which the superiority of this lamp depends is the admission of air into the centre as well as to the exterior of the flame. This is accomplished by the use of a hollow circular wick, capable of being raised and depressed in the oil-tube, by rackwork, so as nicely to adjust its height to the wants of the flame, while at the same time a copious supply of air is insured by the application of a glass cylinder or chimney, upon the due height and dimensions of which much of the perfection of the lamp depends.

Many modifications of the original Argand lamp have been invented, but the tubular wick and chimney are in almost all cases preserved. The leading improvements in the modern Argands relate principally to the position of the oil chamber, which, instead of being above or on a level with the burner, as in the fountain and sinubral lamps, are now transposed to the foot or stand of the lamp, from which the wick is duly supplied by the pressure of a spring, which is occasionally wound up. In this way the inconvenience of the shadow of the oil-holder is avoided. By the use of high and comparatively narrow chimneys, the draught of air is so increased as to admit of the smokeless combustion of several vegetable and coarse animal oils. By similar contrivances lamps have been adapted to the combustion of oil of turpentine (camphine), paraffine oils, naphtha, and other analogous hydrocarbons; but the danger arising out of the ready inflammability and volatility of such oils, and their almost invariable tendency to smoke and throw off flocks of carbon, and exhale disagreeable odours, are circumstances which have of late tended to throw them into discredit.

In the chemical laboratory, and in certain artists' workshops, a variety of lamps are resorted to as sources of heat: in these, common alcohol, methylated spirit, coal gas, and other fuels, are economically and conveniently consumed. [Gas Fitting.]

For simplicity of construction and regularity of action, the *moderator lamp*, invented by M.

LAMP, SAFETY

Franchol in 1836, is undoubtedly the best. In this lamp the oil, which is contained in a cylindrical vessel usually forming the foot of the lamp, is raised to the apex of the Argand wick by means of a piston acted upon by a spiral steel spring. The flow of oil takes place through a narrow tube, which is more or less choked by a conical wire rising and falling in the tube with the piston itself. When the piston is at the highest point of its range, and when consequently the column of oil to be raised is shortest and the spring exerts its greatest power, the thicker part of this wire produces the maximum obstruction in the tube; but, on the other hand, when the piston is near the bottom of the cylinder and consequently the spring has become relaxed and the column of oil is higher, the thin part of the wire only is engaged in the tube, which consequently offers a smaller resistance to the flow of the oil.

Lamp, Safety. [SAFETY LAMP.]

Lampadephoria (Gr. *a carrying of torches*). A torch race, celebrated several times a year at Athens. The work of training the runners was one of great expense, and was classed among the LITURGIES [which see]. In this race each runner had to carry the torch unextinguished over an appointed extent of ground, and hand it on to another. From this, Lucrætiûs has derived his metaphor for human life:

Et quasi cursores vitæ lampada tradunt.

There are, however, difficulties in explaining the details of this race, which can only be accounted for by supposing that several bands ran at the same time, and that those which carried the torch unextinguished to the end were winners above those in which any one of the runners suffered it to go out. (Smith's *Dictionary of Greek and Roman Antiquities*, s.v.)

Lampadite. A variety of cupreous manganese, found at the mines of Schlackenwald in Bohemia, and named after Lampadius, the Saxon metallurgist.

Lampblack. Finely divided charcoal. It is the soot obtained by the imperfect combustion of resin of turpentine; this is burnt in chambers hung with old sacking, upon which the smoke collects, and is from time to time scraped off. It contains about twenty per cent. of peculiar resinous products, water, and saline matter.

Lampic Acid. A term given by Daniell to the acid produced by the slow combustion of the vapour of alcohol and ether in the lamp without flame: it is acetic acid modified by the presence of a peculiar hydrocarbon.

Lampoon. [SATIRE.]

Lamprey. [PETROMYZON.]

Lampyridæ (Gr. *lampyrís*, a glow-worm). A family of soft-skinned Serricorn beetles, of the tribe LAMPYRINÆ [which see], characterised by antennæ closely approximated at their base; head concealed beneath the thorax, or produced in the form of a snout; eyes of the males large and globular; mouth small. In one division the abdomen of the female is luminous; and

LANCASTERITE

the male, which is destined to be attracted by this luminosity, has his head almost entirely occupied by his largely developed eyes, and not produced in the form of a snout. The luminous property of the glow-worm is confined to the two or three terminal segments of the flattened abdomen, which differ in colour from the rest, and are usually yellowish or whitish; this character is peculiar to the true glow-worms, and announces their phosphorescence. The light diffused by the glow-worm is of a lambent, electric, greenish colour: the insect can vary or suspend its luminosity at will. The light-emitting segments preserve their peculiar property for some time after being separated from the rest of the body, and manifest it even in vacuo or when immersed in gases which are not supporters of combustion.

In a second division of *Lampyridæ* the females are not luminous, but are provided with wings; the head is exposed, and is mostly produced in the shape of a snout; the thorax is widened posteriorly, with pointed lateral angles. The elytra, in several, expand posteriorly, where they are sometimes strongly dilated or rounded, especially in the females. To this group belong the genera *Lycus*, *Dictyoptera*, and *Omalisus*.

Lampyrinæ (Gr. *lampyrís*). A Linnæan genus of Coleopterous insects, which constitutes the type of the present tribe of the soft-skinned or Malacodermous Serricorns in the system of Latreille. This tribe is characterised by the enlarged termination of the palpi, or at least of the maxillary palpi; by their soft, straight, depressed, or but slightly convex body; and by the thorax, sometimes semicircular, at others nearly square or trapezoidal, and projecting over the head which it either wholly or partially covers. The mandibles are usually small, and terminate in a slender, arcuated, very acute point, which is generally entire. The penultimate joint of the tarsi is always bilobate, and the terminal claws have neither dentations nor appendages.

The females of some of the Lampyrine tribe are apterous, or have but very short elytra, and are luminous. All the Lampyrines, when seized, press their feet and antennæ against their body, and remain as motionless as if they were dead. [LAMPYRIDÆ.]

Lanarkite. A carbo-sulphate of lead, found at Leadhills, Lanarkshire.

Lanate (Lat. *lanatus*, from *lana*, wool). In Botany and Zoology, when a part is covered with fine, very long, flexible, and rather curling hair, like wool.

Lancaster, Chancellor of the Duchy of. The officer before whom, or before whose deputy, the court of the Duchy Chamber of Lancaster is held. This court has special equitable jurisdiction as to lands holden of the duchy. The office has long been a sinecure, and is not uncommonly appropriated to a member of the cabinet.

Lancasterite. A native hydrate of magnesia, from Lancaster county in Pennsylvania.

(Lat. lancea, Gr. λόγχη). A weapon consisting of a long shaft with a sharp point, much used by the nations of antiquity, and also by the moderns before the invention of gunpowder. The ancient lancea was a general term for missile weapons or javelins: the pilum is termed lancea in Lucan:—

Cujus torti manu commisit lancea bellum.—(lib. vii.)

The Macedonian phalanx and the Roman infantry, as well as the most barbarous nations, all considered the lance as one of the most effective weapons; and even at the present day it is still considered of great value, though it is now borne by cavalry only. Almost all the armies of Europe have now regiments of *lancers*, so called from the lance being the chief offensive weapon with which they are armed. The lances in use among the European cavalry have a shaft of ash or beech wood eight, twelve, or in some cases even sixteen feet long, with a steel point eight or ten inches in length, adorned by a small pennon. [CAVALRY.]

In the middle ages, the terms *man-at-arms* and *lance* were synonymous. To each man-at-arms was allotted a certain number of horses and attendants, such warrior with his followers being then classed as a *lance fournie*. This establishment varied at different periods from three to ten horses. (Hewitt's *Ancient Armour and Weapons in Europe*.)

Lance Corporal. In the Army, the lowest grade of non-commissioned officer. He is distinguished by one chevron on the arm.

Lanceolate (Lat. lanceola, dim. of lancea, a lance). In Botany, a term applied to objects which are narrowly elliptical and tapering to each end, as the leaves, the petals, &c.

LANCEOLATE. In Zoology, an animal or a part is so called when it is oblong and gradually tapering towards each extremity.

Lancers. [LANCE; CAVALRY.]

Land (Ger.). In its widest acceptation, this word is used to denote the solid matter of which the globe is composed, in contradistinction to the liquid matter or water; but in its more restricted signification it is confined to *arable ground*. The latter is the legal meaning of the term; and in this sense it is used in all original writs, and in all correct and formal pleadings.

LAND. In Political Economy. The earliest and most important questions which have occupied the attention of economists are those which are connected with the appropriation, the distribution, and the cultivation of the soil. While some kinds of labour are occupied in the development of useful qualities from raw materials, others with the transfer of commodities from buyers to sellers, and others in promoting and securing the effectiveness of labour itself, that kind of labour which provides first the raw materials of human existence, and next those of comfortable existence, occupies a prominent position for consideration. All those materials of food, of clothing, of shelter, of convenience, are derived from labour exer-

cised on land, either in tilling or mining the soil. Now, as it is clear that the number of persons which can be maintained in any country is primarily to be referred to the rate of agricultural production from the soil, and that, supposing a country imports no food, its population can be no more than the agriculturists in the first place, and the largest number of persons, in the next, who can subsist on whatever remains after the necessities of the agricultural labourer are satisfied, the rate of production from the soil is the gauge of the possible increase of population. And although in a country like this, which has contrived to increase its population largely by the fact that it exchanges a portion of such among its manufactures as it produces beyond its own wants for food from other regions, the existing population is probably much greater than could be maintained from the agricultural produce of the islands, were the whole space as fully utilised as possible; it is still, for obvious reasons, a matter of great importance to decide (as far as may be practicable) the rate of production from land, and the causes, if any, which hinder or prevent a larger increase. So vital was this question to the earlier economists, that the physiocrats of France considered it the first duty of government to develop in every possible way the production of necessities and utilities from the soil, even if the encouragement given should interfere with or check manufacturing and commercial energies; and so strongly was Adam Smith's mind tinged with the reasonings of his friends Turgot and Du Quesnay, that he endorsed in great measure the opinions which the French economists originated. The view, no doubt, is erroneous; but as the standing point of Adam Smith's enquiry was the proportion subsisting in communities between productive and unproductive consumers, the error was natural, and, on the hypothesis of free exchange, harmless.

In order that agricultural produce should be derived from land at all, *security of tenure* is of fundamental necessity. It is clear that as labour exercised on the cultivation of the soil has a prospective and not an immediate return, the labour will not be exercised at all unless the fruits of labour be secured to the agent by which the labour is set in motion. Hence where there is no government, no order, and no protection to person and property from theft or rapine, agriculture ceases; and where protection is accorded uncertainly or capriciously, there, *pari passu*, the energies of labour are diminished, and the development of the art of agriculture is seriously checked. Similarly, where the tenancy of the cultivator is precarious, or the interference of landlords vexatious, or the action of an administration is unfair, it will be found that agriculture languishes, or that out of its many branches of industry those only are prosecuted with energy in which the capitalist or labourer is able to secure to himself the undiminished profit of his activity and intelligence. Thus, for instance, it is quite possible—in conse-

LAND

quence of injudicious conditions in a lease, or of absence of security as to the return of capital laid out in improvements, the profit of which cannot be obtained certainly under the terms of a tenancy at will—that the selection of stock may be made with great precision and care, but that the produce of cereals may be far below that which might be obtained by the concession of more liberal terms to the tenant. In short, the very same element of uncertainty which is fatal, when absolute, to agricultural energy altogether, operates in its degree when any risk, due either to unfairness or caprice, is incurred by the tenant. No one who has ever thought or written about agricultural economics has failed to discern that the highest rate of agricultural produce is inconsistent with a precarious tenure, and that it can be secured only by such a lease as guarantees the tenant the full benefit of all the labour and capital which he may find it expedient to introduce upon his holding.

Tenure of Land.—The kind of tenure possessed by the occupier of the soil is of great significance in comparing the actual and possible rate of production. Ownership in fee, that is possession in the fullest sense and with absolute powers of disposition, is plainly the kind of property which will invite the largest amount of capital for the development of natural resources and for the increase of annual produce. 'The magic of property,' says Arthur Young, 'turns sand into gold ;' but precarious possession, or, as he calls it, a nine years' lease, 'will turn a garden to a wilderness.' It is an economical axiom, that unless a man has full power of disposition, with perpetuity of interest in any possession, he will not be very hearty in improving what his feelings tell him is a mere precarious and temporary estate. This, as we know, applies to building houses, to planting and draining, or to otherwise beautifying property. And if a long term of years, far exceeding the possibility of any individual's life, is not a sufficient stimulant for the highest and fullest improvement of the soil, a life estate will be a still weaker inducement for the permanent outlay of capital. And as by far the largest part of the soil of this country is held for life, it is reasonable to conclude that the application of capital to the soil is crippled and hindered, and that if there were a general substitution of estates in fee for estates for life with remainder in fee, the course of agricultural science would be more rapid, and the application of capital more bountiful and continuous; and land being more freely offered for sale, a larger number of persons would devote their accumulations towards its full improvement. Under existing circumstances landlords cannot and tenants dare not improve, the former because the settlement of estates almost invariably involves great indebtedness, and the latter because they have no security that they will not have to pay interest on their own capital.

Division of Land.—In early English economical history, the feudal baron was the ultimate

lord over all his tenants, as the king was over all his barons. This lordship, however, was a dormant right, called into activity only by the occurrence of escheat, i.e. by the failure of heirs or the operation of a feudal forfeiture on the part of the tenant. Pending such a contingency, the freeholder was secure in the possession of his estate, and after the statute *Quia Emptores* (1290) had full power of alienation, and thus the freeholders of the various manors were generally very numerous. They became more numerous and far more powerful during the fifteenth century, having to all appearance thriven on the civil wars; and the English yeomanry were characteristic of this country up to and long after the Restoration. But the invention of strict settlements, and the gradual accumulation of land in few hands, the fruit of the ingenuity of the two conveyancers, Bridgman and Palmer, left no opportunity for the division of land among other than the wealthiest classes of society, when the yeomanry became gradually extinct. Anything more, however, than a bare statement of the process by which the accumulation of real estate has been and is going on, would far exceed the limits of this article. It is sufficient to mention that the greater part of the land of Great Britain is said to be possessed by not more than thirty thousand persons, and that the number is rapidly diminishing. It cannot be doubted that such a state of things is full of economical evils, and perhaps of political danger.

Value of Land.—Land, notwithstanding the expenses attending its conveyance, always represents at present the largest number of years' purchase, or, what is in effect the same thing, the lowest rate of interest. This was not always the case. In the middle ages land was commonly sold at ten years' purchase, and from the time of the Reformation to the beginning of the eighteenth century was seldom worth more than twenty, and commonly only fifteen, years' purchase. Its rise in value is due to many causes. The most obvious is the large increase in rent for the same parcels of land during the last fifty years. It is probable that rents have more than doubled within the present century, and there is reason to believe that the rise in rents is still progressing. Part, therefore, of the increase is due to the prospective advantages of ownership. The scanty amount of land in the market, and the number of persons who, having accumulated wealth, are eager purchasers of land, is another cause for a factitious price. Something, too, must be allowed for the political and social influence which in all countries is appended to the visible possession of the soil, and which in some cases operates so prejudicially to public interests in preventing the distribution of encumbered estates. But it would be a great error to confound, as is constantly done, the low rate of profit obtained from land as an investment, with the rates of profit derived from the abundant application of capital to

land already purchased and cultivated. There are probably few natural objects from which, at the present time, larger actual rates of profit can be derived than from the cultivation of land, provided capital be freely and judiciously employed. The very fact, that the existing and prevalent relations of landlord and tenant are not favourable to the full development of produce from land, gives a special advantage to the person who unites at once the position of owner, capitalist, and cultivator.

Small and Great Farming.—Much time, probably, has been wasted on the question whether the occupation of small or large farms is economically better and more profitable. The matter must be decided by local or commercial considerations only. In this country, where capital is abundant, where farming is a special business, and where the landlord and tenant are more rigidly distinguished than in any other community, there is and will be a natural tendency to large farming. Such a system has the advantage of requiring a proportionately less amount of dead stock for its operations, and therefore involves a smaller outlay of capital in certain directions. On the other hand, small farming may be in its way of a higher and more careful character, and be less wasteful of the powers contained in the soil. The failure of a particular crop by the large farmer would be set down as a natural contingency; but in the case of a small farmer, an effort might be, and probably would be made, to substitute another crop for the failure, before it is too late to procure one. M. Michelet has dwelt with great distinctness and eloquence on the untiring and devoted energy of the small French farmer. But in countries where capital is scanty, manufactures few and dispersed, and commerce of secondary or little importance, a system of small farming upon permanent holdings becomes an economical necessity. It would be impossible to transfer the English farming system to India, to France, or to Russia; and there can be no doubt that much of the misery and agrarian violence of Ireland is due to the fact, that a land system derived from English legal precedents and legal principles has been forced upon the peasantry, in place of the ancient and more natural tenures to which they were accustomed.

Rate of Production from Land.—Very little information as to the comparative productiveness of the soil in past and present times has hitherto been published, although the enquiry would have been of great historical significance, since it is manifest that the rate of production is the measure of population. From researches which have been carried on for some years past by the writer of this article, it can be proved that the increase in the rate has been far more considerable than would have been imagined, except on an investigation of facts. It is, perhaps, not too much to say that the average produce of grain from well-cultivated land in the United Kingdom falls little short of forty bushels the acre; including, that is to say,

wheat, barley, oats, and the leguminous plants. In some parts of England it is, of course, vastly higher. The writer was informed by a friend—the present (1865) president of the British Association—that in one field which was pointed out to him on the eastern side of Suffolk, ninety-six bushels of wheat were in 1864 reaped to the acre; and the same authority further stated, that, conceiving there must be some mistake, he was assured on enquiry that the amount was not exaggerated. Now it is certain, as the writer can testify from the inspection of many thousand farm accounts of the fourteenth century, that the rate at that time was little over twelve bushels an acre, the amount generally reaped on the American corn lands. Then the system of agriculture necessitated fallows, drainage was imperfect, stocks of cattle were small, weak, and slow in coming to maturity, and the mediæval agriculturist was unprovided with artificial grasses, root crops, and artificial manures. The breed of horses was small, ill proportioned, and weak; so that the power used was expensive and inefficient. On the whole, it may be concluded that ten times the amount of produce, at the very least, is procured from areas equal to those devoted to agricultural purposes five hundred years ago; that consequently ten times the number of persons can be maintained on the same surface, and that the rise in rents, probably eighty times over that of the same land, is due to the enormously increased power of production which agricultural science has rendered possible.

Law of Increase from Land.—Mr. Malthus, in the course of his *Inquiry into the Causes of Population*, a work which forms an era in economical science, was led into a hasty generalisation, which he expressed in an awkward metaphor; namely, that population increases in a geometrical, food in an arithmetical ratio, and that in consequence there were certain physical, pathological, and moral checks to population, in the absence of which the increase of mankind would soon outgrow the means of subsistence. When the theory is corrected, the assertion amounts to this: That when the fertile or most fertile lands in any community are exhausted, the necessity for procuring food compels the cultivation of less fertile lands, and that the phenomenon of rent occurs; the amount of rent being an index of the amount of pressure put upon population by the urgency of the demand for food. There is, therefore, this law traceable: That increased quantities of food are produced at a cost increased above the rate at which food was produced before the demand arises, and that every pressure put upon labour for the means of subsistence, and met by a response, implies an equal return at a necessarily increased charge.

This is not the place in which to discuss the theory of rent [RENT]; but it may be stated that a diminution in the cost of production does not necessarily imply a diminution in rent, for as the taker of the soil at rent is

LAND, DISTRIBUTION OF

governed by precisely those motives which influence any other person in any other calling, that is to say by the disposition to procure the average rate of profit on capital and wages for labour, any diminution in the cost of production (prices remaining stationary, or low prices in one department of agricultural labour being compensated by higher prices in another) will simply bring into play that competition for the use of land which is followed by a rise in rent. It is, no doubt, a condition that the demand for articles the cost of producing which is diminished, should increase in the ratio of diminution in order that these effects should be produced on rent; but there is no object in demand which, by its limited quantity and by the fulness with which it satisfies, on the condition of labour, so many demands, is so little liable to diminution in value, as a consequence of a diminution of cost in producing supplies, as the use of land.

In fine, while, as a result of extended trade, the risk of scanty supply in the first necessities of life is remote and problematical, the question whether the supply of some among the first conveniences of life, as for instance meat, is not unduly exalted by an unnaturally deficient rate of production, is one of great and immediate interest; and with it must be taken the further question, how far this deficiency is to be ascribed to the causes indicated in the article, namely the peculiar tenure of land in this country, and the necessary absence of many among the stimulants to increased productivity.

Land, Distribution of. The land, or solid portion of the earth's surface permanently above the level of the water surface, is distributed with great apparent irregularity, very large portions being collected in one part, and wide tracts of sea separating these from the other parts. Thus, for example, the area of land north of the equator is very much larger than that which is on the south, and that on the eastern side of the Atlantic Ocean is much larger than that on the western side of the same great tract of sea.

The whole surface of land is estimated at fifty-one millions of British statute square miles, more than three-fourths of which lies north of the equator. Of the temperate zones, the land is thirteen times greater in the northern than in the southern hemisphere. Of the whole area occupied by land, only about one twenty-seventh part has water opposed to it in the opposite hemisphere.

A very remarkable excess of water occurs in the hemisphere whose pole is the antipodes of the south-western extremity of England. An observer so placed as to see the whole of that half of the earth of which the south-western extremity of England is the pole, would have almost all the land in view, while the opposite hemisphere would exhibit an almost unbroken water surface. This extreme difference of the two hemispheres is very remarkable.

The most recent estimates of the relative proportion of land and sea are those of Sir

LAND STEWARD

John Herschel, who fixes the ratio at seven to eighteen. If the whole surface of the earth be estimated at 100, there are thus 28 parts of land to 72 parts of water.

Of the whole land, estimated at fifty-one millions of square miles, one twenty-fourth part is detached land or islands, and the remainder (Australia being regarded as a continent) is continental.

Land, Form of. There are many important general facts worthy of remark in reference to the form of land. Of these, the pyramidal termination southwards of all the principal land is very remarkable. Africa, Australia, and South America, all exhibit this peculiarity in the southern hemisphere. Hindustan, Arabia, Malacca, in Asia; Italy and Greece, in Europe; and California, in North America; afford similar examples in the northern hemisphere. There are few important exceptions.

The indentations of coast lines are next in order among the phenomena of the form of land. All the eastern coast of the North Atlantic Ocean is deeply indented in detail, while the western coast is little broken. Africa is remarkably free from bays and gulfs, and contrasts singularly with Europe in this as in many other respects. [Coasts.]

The forms of islands are worthy of notice. Those adjoining great continental masses not unfrequently range parallel to the direction of the land. The British Islands, Madagascar, Japan, the islands of the Indian Archipelago, and the Kurile islands are examples. Islands absolutely detached are often in groups of definite form. The islands of the South Pacific, and some of those off Africa in the Atlantic, are instances. [Island.]

The form of land in respect to elevation is another point for consideration. MOUNTAINS, TABLE LANDS, and VALLEYS, all of which are referred to in special articles, exhibit the most marked varieties. [STEPPIES; DESERTS; LLANOS.] Very important general principles in Physical Geography are involved in the consideration of these questions.

Land Springs. Land springs are sources of water which only come into action after heavy rains; while constant springs, which derive their supplies from a more distant and deeper source, flow throughout the year. All springs owe their origin to rains. In the case of land springs, the water, when it sinks through the surface, is soon interrupted by a retentive stratum, and forms a spring, which ceases to flow soon after the cause which gave it birth has ceased to operate; but the water which supplies constant springs sinks deeper into the earth, and accumulates in rocky or gravelly strata between impermeable beds; and when these are pierced, the water often rises above the surface. [ARTESIAN WELL.]

Land Steward. A person who has the care of a landed estate, and whose duties vary in different countries according to the mode in which landed property is managed. In England, where the landlord very commonly under-

LAND TAX

takes to keep the buildings and fences of his tenants in repair, the duties of the land steward are constant and multifarious; while in Scotland, where the buildings and fences are kept in repair by the tenant, the duties of the steward are limited to receiving the rents, and seeing that the covenants of the leases are duly fulfilled. In many parts of the Continent, and particularly in Italy, where the landlord is a partner with his tenant and shares the produce with him, the duties of the land steward, or *fattore*, as he is there called, are much more onerous than in Britain.

Land Tax. In Finance, a deduction, for the purposes of public expenditure, out of the profit derivable from the rent of land, or from its produce. Land taxes almost invariably form a part of the revenues of the king or of the administration in all settled countries. In the great majority of cases, they are of the nature of a tithe; that is, the government takes a variable portion of the produce either in kind or at a valuation of the produce, and sometimes in addition to this form of the tax determines what kind of crop shall be grown either wholly or partly on the land occupied by the cultivator, as in India, where the growth of opium and indigo is enforced by such regulations. However objectionable may be the form or the effect of such taxes, they are, generally speaking, a necessity, there being no means in poor countries by which a revenue can be obtained except by a land tax in the case of the wealthier part of the community, and by a poll tax, and some excise or customs duty on an absolute necessary of life, as salt, which will be borne by the poorer classes. A land tax will be found to exist in every European state, and is a fundamental feature in the Indian revenue system, where it is enforced by a legal maxim, that the absolute and real ownership of the soil is the property of the monarch and, by implication, of his successors, the actual owners being considered as occupiers paying, as the case may be, a fixed or a variable rent. So ancient is this theory of a land tax, that it is found in the Vedas.

For the effects of a land tax, the reader is referred to the article TAXATION; at present it will be necessary only to trace the history of the English land tax. In feudal times, the fiscal necessities of the sovereign were supplied partly from the profits of feudal incidents, as fines, reliefs, and the like; partly from grants in parliament, consisting of contributions from personal property under the name of *tenths*, *fifteenth*s, &c.; partly from escuages, originally compositions for military service on the part of tenants of the crown, and arbitrarily imposed; but made liable to the discretion of parliament by a clause in the great charter, requiring assent to their imposition. These escuages were virtually a very heavy land tax, being (if we can trust the value given to a knight's fee in the time of Edward I., and its identity with the same quantity in the reign of Henry II., rather more than a hundred years

before) twenty-five per cent. on the gross rental.

In the reign of James I. an attempt was made to effect a composition between the crown and the military tenants, on the basis of commuting the variable incidents of their tenure into a fee farm rent. The plan failed, not, it appears, because the terms of the composition were unfair, but because a fundamental feature in the scheme was the extension of the same composition to the inferior tenants, whose dues were payable to mesne lords, but whose payments on behalf of the lords should be made *through the crown*. With some reason, perhaps, the mesne lords felt that the security offered for their portion of the feudal incidents was of a somewhat problematical character, and the capricious imposts of military tenure were suffered to continue.

A heavy, but on the whole equitable, land tax took the place of the ancient system during the Protectorate. As at the Restoration the acts of the government immediately preceding the re-establishment of the monarchy were nullified, on the quibble that Cromwell had not been a *de facto* king, and therefore not within the statute of Henry VII., which gives legal authority to *de facto* governments, the feudal incidents, not having been technically abolished, were necessarily revived; but being felt to be intolerable, their abolition was determined on in the parliament of Charles II. To save the rights of the crown, and at the same time to give an equitable means of relief to the military tenants, it is clear that a tax or tithe should have been imposed; but the parliament, by a majority of one, and in defiance of the remonstrances of the members from the leading towns, abolished the feudal incidents, and compensated the crown by the grant of the hereditary excise. In other words, the landowners emancipated their estates at the expense of the general community.

At the time of the Revolution, it became necessary to support the new establishment by some general sacrifice. Hence, while additional customs and excises were levied, it was no longer possible that land should escape, and in 1693 (4 Wm. & Mary c. 1) a tax was imposed, for the first time since the Restoration, on land. It must be remembered that it was preceded by the hearth and the poll tax, as well as by a variety of similar imposts. The land tax was originally annual, and was assessed on a voluntary principle. Hence it is said (and it is difficult otherwise to account for the singular inequality of the present assessment), that while the friends of the new establishment rated themselves at the full amount of the tax, the Jacobites, too numerous to be affronted or even compelled to contribute to the real exigencies of the state, assessed their contributions at low and even nominal amounts. Be this as it may, the principle on which the assessment was made remained unaltered; and the rate at which a land tax is paid on the income of real estate, and the net proceeds of

LAND TRANSPORT CORPS

patent offices, is identical with that created at the first imposition of the charge.

The full land tax was four shillings in the pound. It appears that the amount was determined by the legal rate of interest at that time, viz. six per cent. But the tax during the first eighty years of its annual imposition was seldom levied at the full rate, land taxes of one, two, and three shillings being ordinarily imposed in time of peace. At the outbreak, however, of the American war, the tax was finally fixed at four shillings on the old assessment, and made perpetual; and ultimately being reckoned as a permanent government lien upon land, it was made capable of redemption, on the payment of its capitalised value, the proceeds of the redemption being applied to the purchase and extinction of a portion of the national debt. The sums received for redemption of land tax, and applied to these purposes, were 75,477*l.*, 55,457*l.*, 42,953*l.* in the years 1861-2-3 respectively.

As the rent of land increases largely without exertion or risk on the part of its owners, it seems natural that it should contribute largely to the public revenue; the more so, as the growth of population is the true cause of the increase of rent. Hence Mr. Mill has urged, that there could be no possible injustice, in case the present value of the land were permanently secured to the owner, in appropriating for the public service all increase in its value, provided such an increase were derived solely from the demand arising from unimproved sites, or for soils on which no capital is being fixed. It is difficult, nevertheless, to see how, if such a theory were adopted in practice, the stimulus to improvement of the soil would be operative in future.

Land Transport Corps. A corps which at the time of the Crimean war performed the duties now carried on by the Military Train. [MILITARY TRAIN.]

Lands. In a rifled gun, the portions of the bore between the grooves.

Land-locked. A term applied to a harbour or piece of water which is so environed by land on all sides as to exclude the prospect of the sea, unless over some intervening land. If a ship is at anchor in such a place, she is said to ride land-locked, and is therefore considered to be safe from the violence of wind or swell of the sea.

Landammann (Ger. landammann). In Switzerland, the president of the diet of the Helvetic republic. The highest magistrate in ten of the cantons also bears the title of landammann; in the others he is designated by various appellations.

Landau. The name given to a carriage which may be opened and closed at the top; so called from Landau in Germany, where they were originally made.

Landes (Fr.). In France, sterile plains covered with heath or broom are so called (probably from the Teutonic 'land'). They have given their name to a department abounding in them (part of the ancient Guyenne).

LANDSCAPE GARDENING

Landfall. The first land seen after a voyage is so called. A good landfall is when the land is seen as expected.

Landgrave (Ger. landgraf). A title taken by some German counts in the twelfth century, who wished to distinguish themselves from the inferior counts under their jurisdiction; and thus assumed the designation of land-graf, or count of the whole country. This was the origin of the landgraves of Thuringia, of Lower and Higher Alsace, the only three who were princes of the empire.

Landmark. A term denoting, in a general sense, anything by which the boundary of a property is defined. In ancient times the correct division of lands was an object of great importance; and various means were adopted to give distinctness and permanency to boundaries. Stones and hillocks were the most usual landmarks. The importance of this subject, among the Israelites particularly, may be judged of from the denunciation, 'Cursed be he that removeth his neighbour's landmark.'

In Naval language, the term *landmark* is applied to any conspicuous object which serves as a guide in entering a harbour, or avoiding a danger.

Landreeve. A subordinate officer on an extensive estate, who acts as an assistant to the land steward.

Landscape (the termination *scape* in this word answers to the German suffix *schaft*, which is really a participle of the verb *schaffen*, to make). The scenery presented to the eye in the country; as also, in its more common acceptance, a picture representing such scenery. A landscape in the latter sense may, however, become allegorical and historical, in the meaning applied by artists to those terms. The chief study of the landscape painter is the vegetable world, air, water, rocks, and buildings. To these he may impart an ideal beauty, and thus elevate his art above mere topographical painting; a term which may be applied to his work, if he merely copies without refinement what is presented to his eye. A landscape may be equally elaborated in all its parts, with a due observance of aerial perspective, because the eye is not necessarily more fixed in viewing a picture than it is in looking at natural scenery. The parts of a picture are viewed in succession, just as the various parts of a landscape present themselves in nature.

Landscape Gardening. The art of laying out grounds so as to produce the effect of natural landscape. Its principles are the same as those upon which the landscape painter proceeds in composing a picture; and though it is an art of which, like many others, everybody thinks he is a judge, it requires, to be properly practised, powers of a much higher order than fall to the lot of most men. Brown, commonly called Capability Brown, was the first who practised the art in this country so as to render himself worthy of the name of an artist. To lay down the principles of the art would be quite impossible in this article; but this gene-

LANDSLIP

ral observation contains the sum of them : Let selected and beautiful nature be constantly taken as the model, and success must follow.

Landslip. In Geology, a sliding of the land which occasionally takes place near a cliff or mountain side, owing generally to the removal of some supporting stratum by the action of water eating away and undermining the bed, or by frost expanding and contracting some material through which water passes. The immediate causes of landslips are sometimes natural springs; but more frequently natural cracks formed during unusually dry summers in clay, at the bottom of which is a bed of sand dipping towards and emerging at a hill side. The fall of the Ross-berg in Switzerland, and the slip that took place some years ago at Charmouth, near Lyme Regis in Dorsetshire, are familiar examples.

Landsman. On board Ship, a sailor who has not previously made a seagoing voyage. The expression *ordinary seaman of the second class* is gradually taking the place of *landsman*.

Landwaiter. An officer of the customs, whose duty it is upon landing any merchandise to taste, weigh, measure, or otherwise examine the various articles, &c., and to take an account of the same.

Landwehr (Ger. *land-guard*). The militia of Prussia and Austria are so called. [MILITIA.]

Langite. A sulphate of copper forming a crystalline crust on Killas, from Cornwall, and named by Professor Maskelyne, after Dr. von Lang.

Langrel. A particular kind of shot formed of bolts, nails, and other pieces of iron, tied together, and forming a sort of cylinder which corresponds with the bore of the cannon from which it is discharged. It was used chiefly to destroy the masts and rigging of the enemy's ships. The term is now obsolete.

Language (Fr. *langage*, from Lat. *lingua*, *the tongue*). Language may be defined as 'the expression of ideas and their various relations by certain articulate sounds, which are used as the signs of those ideas and relations.'

The only speaking animal is man: and from this fact it would seem to follow that the analysis of language must in the end determine the essential distinction between the mental constitution of man and that of brutes. The progress of physical science is constantly lessening the interval which was supposed to separate the bodily structure of man from that of brute animals; and a fold of the brain seems to be almost the only perceptible distinction between them. If, taking all his powers together, we may speak of man as the strongest or most enduring of all animals, yet in many individual attributes he is far surpassed by many; nor do we gain much by taking our stand on his higher moral or spiritual nature. The arguments which are urged to prove an inherent immortality in the human soul, go far, as Bishop Butler has shown (*Analogy* part i. ch. i. p. 25), to establish the same immortality for brutes. It is also clear that our senses differ in no

LANGUAGE

respect from those of lower animals. With the memory of brutes is combined the power of distinction and comparison; while it is certain that they feel pleasure and pain, and exhibit the signs of love and hatred, shame and pride. They have a strength of will which may be not unfrequently matched with that of the human will; and if they are guided in part by instinct, the same must be said of man during the stage of infancy: but no mere instinct will account for the determination with which the spider proceeds to repair its injured web, or gives up its task when it is seen to be hopeless. It is clear also that brutes can communicate to each other their wants and their designs; and the mere power of imitating articulate sounds is possessed in a high degree by the parrot, mocking-bird, and other animals. But whatever their sensations or ideas may be, it is certain that they are not such as to compel the creature to give utterance to them in articulate speech. This defect or limitation, therefore, seems to mark the real distinction between the very highest brute creatures and man, and to result from the incapability of forming any *general ideas*, or of advancing beyond acts of particular perception. In wood, stone, and iron, men may see the common characteristic of hardness, or that of malleability in gold and iron, or of whiteness in snow and milk. This power of generalisation seems to be wholly wanting in brutes. 'If,' says Locke, 'it may be doubted whether beasts compound and enlarge their ideas that way to any degree, this, I think, I may be positive in, that the power of abstracting is not at all in them, and that the having of general ideas is that which puts a perfect distinction betwixt man and brutes, and is an excellency which the faculties of brutes do by no means attain unto.'

But it is obvious that such a conclusion remains a mere deductive theory, until a complete analysis of language has shown that the elementary predicative roots of human speech are such expressions of general ideas. Hence the desire to obtain an answer to some of the most momentous questions, relating to the past history and the future condition of mankind, renders a classification of existing languages a matter of primary necessity. Before the introduction of Christianity, no attempts at any such classification were ever made. The Greek, regarding all races except the Hellenic as mere barbarians, cared nothing for dialects which he despised as unintelligible jargons; and although he subjected his own language to a minute philosophical analysis, there was nothing in the process to lead him to examine the history of its growth. The work of grammatical analysis was first rendered practically necessary by the extension of Roman dominion. When Latin historians adopted Greek as their literary language, such grammarians as Dionysius the Thracian, carrying out the work already begun by the Alexandrine editors, especially in Homeric literature, soon elaborated that grammatical nomenclature in which European scholars have been

LANGUAGE

trained from their days to the present. But this technical system had been already carried to far higher perfection at a much earlier time in a land of which Greeks and Romans knew nothing. The Sanscrit grammarians had examined with extreme minuteness the whole field of their own speech, embracing every form of the language, regular and irregular, and supplying rules for the employment of every word; and the resemblance of their terminology to that of the Greeks at least proves resemblance if not identity of structure between the two languages. But beyond this task of mere analysis it was impossible to advance except by a comparison of other languages with that which was under examination; and there is no evidence to show that the Greek discovered any marks of affinity between the inflexions of his own language and that of the Latin; while it is certain that Caesar did not see in the language of the Gauls whom he conquered, a speech which was radically the same as that of his own soldiers. The narrow exclusiveness of national feeling, which led to this contemptuous neglect, received its first blow by the introduction of Christianity, and those who were imbued with its spirit were not long in learning that all dialects except one or two were no longer to be regarded as barbarous. But unfortunately certain theological prepossessions interposed new barriers in the way of a really scientific investigation of language. It was assumed that because all human speech was originally one, therefore all languages were sprung from Hebrew, and might all be traced back to that source. On this task the labour of ages was expended, yet not altogether wasted. If, by dint of twisting and straining, a few words might be said to resemble words of some thing like a similar meaning in Hebrew, a vastly larger number obstinately resisted the process; while the observations of missionaries and other persons gradually discovered nearer resemblances between words in European languages and words belonging to dialects far more distant geographically than that of the Hebrews. Thus the Spanish Jesuit Hervas identified the Greek *θεός* with the Sanscrit *deva*, and *ειμή* with the Sanscrit *ásmi*. But further thought or research showed that no certain bounds could be placed on the importation of words from one language to another; and that, as long as men were busied only in making lists of words simply from their phonetic resemblance, they were drawing up mere barren catalogues of similar sounds. This conviction led Leibniz to maintain that if anything was to be done to good purpose in the classification of languages, it must be by a diligent accumulation of facts, and by a careful arguing from the known to the unknown; and as soon as it was felt that languages must be classified not by similarity of words, but wholly by their grammatical construction, the attainment of a true science of language was insured. The attention of grammarians was thus turned more and more to an examination of inflexional forms, and it was admitted that without a knowledge of their

origin and nature we could not be said to have a real knowledge of the languages in which they occur. Thus if the addition of *d* to *love* converts a thing of the present into a thing of the past, if *r* added to *amo* changes an active verb to a passive one, we must know what these letters *d* and *r* really are, before we can claim really to know our own language or the Latin. Hence in each case it became necessary to trace back each given word with its inflexions to the oldest form in which they appear in that language. The present forms of English words vary indefinitely from those of the same language in long past ages: and therefore we have to trace our present terminations and suffixes through every period of our language to Anglo-Saxon; but this very name shows that we cannot stop here; and after comparing that dialect with the Saxon of the Continent, we must compare it with every other Low German dialect, and these with all other German dialects, until we reach the Gothic of Bishop Ulfilas.

But if by so doing we establish the fact of a certain group of languages connected with each other, we have not determined the nature of that connection. Is the Gothic the parent of this whole group, or itself the outgrowth of some earlier stock? Are there other languages besides these belonging to the same branch, or others which with them make up a larger class of languages? and if so, what place does this class occupy in the great field of human speech? The same questions demanded an answer from those who examined what are known as the Romance languages. It was clear that French, Spanish, and Italian were related to each other, but are they sprung from the Latin directly, or through the intermediate Provençal? and again, is Latin really the one source of all, and has the group to which these dialects belong anything to do with the Hellenic dialects on the one side, and the Teutonic, with the German and English, on the other? Such a classification, if possible, would go far towards solving the most important problems connected with human speech; and such a classification became possible when European philologists became acquainted with Sanscrit. This language, which is admitted by all to have been the language of the Brahmans in the time of Alexander the Great, carries us back by the internal evidence of its literature to at least the second millennium before the Christian era. But the mere question of its age is of secondary interest: its real importance lies in the light which it throws on all the European languages except such allophylian languages as the Basque. [TURANIAN LANGUAGES.] The system of Sanscrit grammar was seen to be substantially identical with that of the Greek: the same laws were discerned as regulating the declensions and conjugations of both; their numerals, articles, and pronouns were the same, while many words which were used as prepositions in the Greek were found in the form and with the force of nouns in the Sanscrit. Hence the conclusion was finally established

LANGUAGE

that the relation of languages was to be measured by the similarity of grammatical forms, and that this resemblance must in its turn be tested by the laws of phonetic change. The relative age of each remained a question wholly of internal evidence, but it was clear that the presence of a single more perfect grammatical form was proof that the language in which it was found could not be the offspring of any other in which the same form existed in a less perfect state. We may take the following paradigm of the auxiliary verb:

	Italian	Wallachian	Spanish	French
<i>I am</i>	sono	sum	soy	suis
<i>Thou art</i>	sei	es	eres	es
<i>He is</i>	e	é	es	est
<i>We are</i>	siamo	suntemu	somos	sommes
<i>Ye are</i>	siete	su'nteti	sois	êtes
<i>They are</i>	sono	su'nt	son	sont

These, it is clear, are mere variations of one common type; but none of them explain themselves. We cannot understand why *sum* in Wallachian should be *soy* in Spanish, or why *suis* in French should in the second person change into *es*. These forms, then, could not have originated on French, or Italian, or Wallachian soil. But by the aid of Sanscrit we obtain another set of paradigms.

	Sanscrit	Lithuanian	Doric	Latin	Gothic
<i>I am</i>	āsmi	esmī	ēsmi	sum	im
<i>Thou art</i>	asi	esi	ēsi	es	is
<i>He is</i>	asti	esti	ēsi	est	ist
<i>We (two) are</i>	'avns	esva	ēvns	...	siju
<i>You (two) are</i>	'sthas	esta	ēstas	...	sijuts
<i>They (two) are</i>	'sthas	(esti)	ēstas
<i>We are</i>	'avns	esmi	ēvns	sumus	sijum
<i>You are</i>	'sthā	este	ēstā	estis	siju
<i>They are</i>	santi	(esti)	ēsti	sunt	sind

This table, it is true, exhibits some older forms, and carries us a stage or two farther back in the history of their development; but we cannot say that we find in any of them the common and earliest type of them all. That the Sanscrit is not the original, is clear from the fact that the Greek form is in many instances more primitive. The Sanscrit *'smās* has lost the radical vowel which is retained in the Greek *ēsmi*; and the same remark applies to the Sanscrit *'sthā* as compared with the Lithuanian *este* and the Latin *estis*. So again the Greek *ēvri*, for *ēvns*, has lost the radical *as* altogether, while the Latin has at least preserved the *s* in *sum* = *santi*. A comparison of the two tables still further refutes the theory of Raynouard, that Provençal alone was the daughter of the ancient Latin, and in its turn the only source of French and Italian, Spanish, and Portuguese. The crippled Provençal forms, *sem*, *ets*, *son*, could not possibly have been changed back into the more primitive French forms *sommes*, *êtes*, *sont*. But it remains nevertheless a fact, that the English *am*, the Latin *sum*, the Greek *smi*, the Lithuanian *esmī*, and the Sanscrit *āsmi*, are all variations of one common type, and that this type was furnished by the language spoken before the separation of the progenitors of the several tribes or races which have spoken these or other cognate dialects down to the present time. And this fact of an affinity which has nothing to do with

subsequent intercourse (for the majority of these races have, since they left their common home, been as much separated as if they had been inhabitants of different planets) furnishes also the measure for determining to which language any given word belongs. No facts in philology are better ascertained than these, that the grammatical systems of languages are never exchanged, and that there cannot, therefore, be such a thing as a mixed language. But words may be imported to any extent. The Persian vocabulary is full of Arabic words; the Araucan dictionary has even a larger number of Spanish than of Indian words; yet the inflexional system of these languages is in no way affected by the circumstance. If, then, we find that the Latin *vinum* represents the Greek *olvos*, *wine*, and the Latin *ovis* the Greek *ōis*, *a sheep*, it may be possible, probable, or certain, that the Latin may have imported the word from the Greek; but a notion of conscious borrowing cannot possibly be applied to the words in the following table:—

	Sanscrit	Greek	Latin	Slavonic	Irish
<i>Father</i>	pitar	patēr	pater	...	athair
<i>Mother</i>	mātār	matēr	mater	mati	mathair
<i>Brother</i>	bhrātār	phratēr	frater	brat	brathair
<i>Sister</i>	svāsār	phratēr	soror	sestra	sior
<i>Daughter</i>	dūhitār	thuyátrōp	...	dukte	dear

Such comparisons, while they prove the absolute impossibility of borrowing or importation from one dialect into another, throw also a flood of light on the social and moral condition of the several races, and of the common parents from which they sprang. The names for numerals, for domestic and other animals, for articles of clothing, for agricultural and other implements, for houses and other buildings, and for natural phenomena, furnish indisputable evidence of their social condition, both intellectually and morally. But this subject, momentous and interesting as it is, belongs properly to the history of Aryan civilisation, and cannot be further treated here. It is more necessary for our present purpose to remark that a comparison of these inflexional systems shows that the Latin never passed through the Greek; while it becomes, for similar reasons, equally certain that the Romance languages have not sprung from the Latin, but owe their origin to unwritten Italian dialects, sprung from the same stock to which the Latin itself belongs. This conclusion is of the highest importance, as it enables us to rate at their true value the literary dialects of Greece, Rome, and England. Such languages, however graceful or powerful, have passed into an artificial condition of arrested growth, and are really in a state of decay. They have lost the power of regeneration which the vulgar dialects retain; they are exposed not less than the dialects to phonetic corruption, and cannot issue out into new forms by any powers of their own. Into this state of stagnation the Latin dialect was brought when it became a literary language. 'It could not grow,' says Professor Max Müller (*Lectures on Language*, first series, p. 58), 'because it was not allowed to change

LANGUAGE

or to deviate from its classical correctness. It was haunted by its own ghost. Literary dialects, or what are commonly called classical languages, pay for their temporary greatness by inevitable decay. They are like stagnant lakes by the side of great rivers. They form reservoirs of what was once living and moving speech, but they are no longer carried on by the main current. At times it may seem as if the whole stream of language was absorbing these lakes, and we can hardly trace the small rivulets which run on in the same bed. But if lower down, that is to say later in history, we meet again with a new body of stationary language, forming or formed, we may be sure that its tributaries were those very rivulets which for a time were almost lost out of our sight. . . . As soon as a language loses its unbounded capability of change, its carelessness about what it throws away, and its readiness in always supplying instantaneously the wants of mind and heart, its natural life is changed into a merely artificial existence. It may still live on for a long time, but while it seems to be the leading shoot, it is in reality but a broken and withering branch, slowly falling from the stock from which it sprang. The sources of Italian are not to be found in the classical literature of Rome, but in the popular dialects of Italy. English did not spring from the Anglo-Saxon of Wessex only, but from the dialects spoken in every part of Great Britain, distinguished by local peculiarities, and modified at different times by the influence of Latin, Danish, Norman, French, and other foreign elements.' In the same way, a comparison of the several high and low German dialects shows that there never was one common Teutonic language. The Gothic of Ulfilas has no more claim to the parentage of the other forms, than Sanscrit to that of Greek, or Greek to that of Latin. But all these, together with the Celtic, Scandinavian, Lithuanian, and other dialects, point to the common language of an earlier time, when the ancestors of all these branches of the human family still dwelt in the same home.

To this great tribe of languages, Frederic Schlegel gave the name Indo-European; but this title, as upholding too much that geographical system of classification which had been the fruitful source of so many errors, has been displaced by that of Aryan—a designation adopted by large portions of this family of nations, if not claimed originally by the parent stock itself. The root of this name is found in Gr. *ἄρα* and *ἀποιρ*, Lat. *arare*, in the participial forms *erds* and *earth*, and in *earring*, an old English word for harvest; but the distinctive force of the root was lost when, from the sense of ploughing and tilling, it passed into a mere title of honour. Thus in the Vedic literature Arya and Sudra give an exhaustive division of mankind, and the Persian distinction of Iran and An-iran is familiar to all. But the evidence furnished by the language, the discovery of which rendered this classification possible, has produced consequences still more important.

It has swept away all those theories which treated language as the result of conscious agreement, and which discerned that agreement in the formal, as distinguished from the radical elements of speech, or, in other words, regarded the inflexional terminations of nouns and verbs as arbitrary additions which originally had no meaning. It has shown that all such terminations existed in earlier forms of language as separate words, while it exhibits the workings of similar combinations in more recent dialects. Thus the paradigm of the substantive verb already given, shows that the word for the first person consists of the radical *as*, denoting breath or life, and the personal pronoun *mi*; and the English *am* is as much made up of these two elements as is the Sanscrit *āsmi* or the Lithuanian *esmi*. The other persons of the several numbers are formed by adding to the root the pronouns expressive of those persons; and this process is seen in all varieties of Aryan dialect, although the substitution of a synthetical for an inflexional structure has to some extent obliterated the earlier forms in many modern languages. This result must, doubtless, be in part attributed to the expression of personal pronouns in such languages; the phrase *ἐγώ εἰμι*, or *I am*, is strictly speaking tautological; but the practice is sure in the end to weaken the inflexional structure of a dialect to which it is applied. The closeness of the parallelism in earlier stages of speech is exhibited in the following paradigm:—

	Sanscrit	Greek	Latin
<i>I give</i> . .	dāda-mi	dōda-mi	dō
<i>Thou givest</i>	dāda-si	dōda-si	dā-s
<i>He gives</i> .	dāda-ti	dōda-ti	dā-t
<i>We give</i> .	dāda-mas	dōda-mes	dā-mus
<i>Ye give</i> .	dāda-tes	dōda-tes	dā-tes
<i>They give</i> .	dāda-ti	dōda-tes	dā-nt

But although in the Latin *dō* the reduplication of the root and the pronominal suffix has been as much lost as in the French *aime*, yet when needed phonetically, the suppressed suffixes are always at hand. Thus we have in French *il aime*, Lat. *amat*, *he loves*; but if the expression is to be inverted, we have immediately *aime-t-il*? The method of forming the tenses has been illustrated in the articles IMPERFECT TENSE, FUTURE TENSE, &c.; and we need only remark that what holds good of Greek and Latin, holds good also of French and Italian. The French future is formed by adding to the root of the verb the inflexions of the present tense of *avoir*, to have; and if after examining the terminations any doubt remained, it would be removed by a reference to the uncompounded Provençal future, *dir vos ai*, *dir vos em*. The choice of this verb to express future time was arbitrary; but the choice once made, the old grammatical law at once took effect. This instance, however, may serve to show the infinite variety of forms which the same language may assume. It is obvious that instead of taking the Latin *habeo*, *I have*, as the base of the tense, *dirai* = *habeo dicere*, the present

tense of *vado*, I go, might have been adopted, and with *diversis* a very different form of inflexion would at once have been the result.

The words already examined show further that our nouns and verbs are made up of two radical components, which cannot be further decomposed, and these are the *roots predicative* and the *roots demonstrative*, the latter being sometimes called *pronominal* or *local*. The method (and there can only be three modes) in which the former are combined with the latter determines the class to which any particular language is to be assigned. In many compound words we have, of course, two, or possibly more predicative roots, but in no case have we any mere arbitrary and unmeaning suffix. Thus the English *landscape*, compared with the German *gesellschaft*, exhibits a suffix which is itself the past participle of verb, and the termination *-tepos* in the Greek comparison of adjectives (e.g. *σοφώτερος*) is no pronominal ending, but the predicative root *tar*, to go beyond, which reappears in the Latin *trans* and the French *très* used as a prefix to mark the superlative degree. The adaptability of these roots to express shades of meaning indefinitely removed from the original idea is indeed wonderful. Thus the root *ar*, to plough, was transferred, as in the Sanscrit *aribram*, an oar, from the ground to the sea, which, in Shakespeare's phrase, 'men *ear* and wound with keels.' It thence passed to the idea of labour in general, as in the Old Norse *erfida*, the German *arbeit*, the English *errand*, and finally through the Greek *ἀργός*, *ἀργιστής*, *ἀργός*, Latin *agrestis*, expressing ideas of swiftness, slowness, brilliancy, rudeness, it came to denote in *ars*, art, the highest conceptions of the painter and the poet.

These roots Bopp divided into two classes, roots ending with a vowel and roots ending with a consonant: by Professor Max Müller they are classified as primitive, secondary, and tertiary, the first being simply a vowel, as *i*, to go, or a vowel and consonant, as *ad* to eat, *da* to ; the secondary comprising those which have a vowel between two consonants; while those which have two or more consonants coming together fall under the third class. The possible combinations of these letters would give many thousands of such roots; but in fact the number used is very small. Sanscrit grammarians reckoned them at 1,700, and probably not more than one-third of that number are actually needed. The language of the English peasant is said to be carried on with 300 words, and Shakespeare was contented with 15,000; but 50 derivatives out of only 500 predicative roots would give a list of 25,000 words. The mode in which these roots are used enables us to frame a genealogical classification of languages, as it furnishes evidence that the separation of each from the parent stock did not take place until its grammatical system had been completed. But as such formations as the French future, and the Latin and Greek imperfect, already noticed, show

the wide choice of means available for the construction of new forms, it is perhaps a matter of wonder that we are able to trace the genealogical connection as minutely as we can. In the AGGLUTINATE LANGUAGES [which see] this classification fails us; but the distinction of pronominal and predicative roots supplies another which is absolutely exhaustive. They may be so combined (1) as to preserve the distinct existence of both, and so to exclude all phonetic corruption, or (2) so that the predicative root may remain intact, or (3) so that both the roots may be modified by phonetic changes.

The first mode marks the RADICAL stage of language, and is seen only in the Chinese, which is therefore a monosyllabic language, in which every root is a word and has its own proper force.

The second, or TERMINATIONAL Stage, comprises the agglutinative or Turanian dialects.

The third, or the INFLEXIONAL stage, includes the written and literary languages of the Aryan and Semitic families, which are, strictly speaking, the only *families* of speech fully deserving that title, the characteristics of the Semitic dialects being that the component pronominal and predicative elements are more palpable than in the Aryan languages; and also that every root in the former consists of three consonants, whence they have sometimes received the name of tri-literal.

The laws of phonetic change are of primary importance in the science of language. The analysis of language has led to the conclusion that 'sound etymology has nothing to do with sound.' The true conditions which regulate phonetic changes in Aryan languages are in great measure comprised in Grimm's law, which may be stated as follows:—

'Wherever the Hindus and the Greeks pronounce an aspirate, the Goths and Low Germans generally pronounce the corresponding soft check (*g*, *d*, *b*), the Old High Germans the corresponding hard check (*k*, *t*, *p*).'

Thus (1) if for the English *yesterday* we desire the German and Greek equivalents, we must expect words beginning with *g* and *ch*, and accordingly we find *χθές* in the latter, and *gestern* in the former. (2) The Greek *θῆρ*, a beast, is represented by the Latin *fera*, the German *thier*, English *deer*; and if for the English *dare*, we look for a Greek word beginning with *θ*, we find *θάρρειν*. (3) The Greek *φῆρ* is represented by the Latin *fauna*, the Gothic *bōka*, the English *beech*. (4) The English *quern* or *quean* is the Gothic *qinō*, the Greek *γῆρ*, Sanscrit *janī*. (5) The English *two*, German *zwei*, Old High German *zwei*, answers to the Latin and Greek *δύο*. (6) Few really Saxon words begin with *p*, and none in Gothic except foreign words, while in Sanscrit the corresponding *b* is very seldom an initial sound, its place being occupied with the labial spiritus *v*. (7) The Greek *κέρας* is represented in the Latin *cornu*, *cervus*, English *horn* and *hart*. (8) The English *three* answers to the German *drei*, Latin *tres*, Greek

LANGUAGE

ρῆσις. (9) The English *fars, ferry*, answers to the Greek *ῥῆσις*, and the Sanscrit *char*. For a fuller illustration of these formulae, the reader is referred to Professor Max Müller's *Lectures on Language*, second series, v.

With Grimm's law must be combined four propositions, which may be regarded as constituting 'the Magna Charta of the science.'

(1) The same word takes different forms in different languages, as the Latin *ipse* reappears in the Italian *medesimo*, and the French *même*; but (2) even in the same language. Thus the English has received from the French some words which it already possessed in a Teutonic form, the French *guilt* being thus set by the side of the Anglo-Saxon *wile*, and *guise* and *wise*, *engage* and *wed*, alike became English words. (3) Different words take the same form in different languages. Thus in Danish *good* is *god*; but the identity of sound between the two words is merely accidental. 'The two words are distinct, and are kept distinct in every dialect of the Teutonic family. As in English we have *God* and *good*, we have in Anglo-Saxon *God* and *gōd*; in Gothic *guth* and *God*; in Old High German *cot* and *cuot*; in Dutch *God* and *goed*. Though it is impossible to give a satisfactory etymology of either *God* or *good*, it is clear that two words, which thus run parallel in all these dialects without ever meeting, cannot be traced back to one central point.' But (4) difference of meaning will show that words of the same form in the same language belong really to different roots. The French pronoun *son* represents the Latin *sonum*; the noun so spelt is the Latin *sonum*, sound; *louer*, to praise, is the Latin *laudare*; *lower*, to let, the Latin *locare*. The English *cleave* in the sense of striking is the Anglo-Saxon *clifian*; in the sense of severing, it represents the Anglo-Saxon *cláfan*. But it follows, of course, that words which retain no resemblance to each other may be most closely related. Thus the Sanscrit for *tear* is (*dāsrī*), which appears in Greek as *δάκρυ*, *δάκρυμα*, in Latin as *lacryma*, French *larme*; in Gothic as *tagr*, English *tear*: and thus is established the identity of the English *tear* and the French *larme*.

Finally, it must be remembered that, although man is distinguished from the lower animals by the power of framing and giving expression to general ideas, yet his speech could never have become the vehicle for any but the merest sensuous thought, if it had not passed through the crucible of metaphor. Speaking from comparatively scanty evidence, Locke with marvelous sagacity concluded that if we could trace to their sources all words which now bear an abstruse signification, 'we should find in all languages the names which stand for things that fall not under our senses, to have had their first rise from sensible ideas.' This conclusion is now fully established by the evidence of comparative philology. Words which denote the Spirit of God meant originally nothing more than the breath of the sky: words expressing the soul or life of man, once meant

only air or wind. The wonderful flexibility of these predicative roots may be seen by examining the changes of meaning undergone, for example, by the root *mar* or *mal*, which originally expressed simply the idea of crushing or grinding. With this meaning it appears in the (.....) *μάλα*, the Latin *mola*, the Irish *meile*, and the English *mill* and *meal*. The transition from pounding to fighting is seen in the Greek *μάχεται*—while as expressing the ideas of softening or destruction, the root furnished a name for man as subject to disease and death, the *morbus* and *mors* of the Latins, while the gods were *ἀ-μρτο-ι*, or *im-mor-tales*. Again, under the form *marj*, or *mraj*, the root gave birth to the Greek *μέλας*, and the Latin *mulgeo*, *mulceo*, all meaning originally to *stroke*; and the corresponding ideas of softness, sweetness, and decay were expressed in the Greek *βλάτ*, *μαλακός*, *μαλθακός*, and the Latin *marcidus* and *mollis*. In the same way the root *jan* passed from its original force of making and producing (as in the Sanscrit *janas*, Gr. *γένος*, *γονεύς*, *γονή*, English, *kin*, *king*, *queen*, *quest*) to the abstract idea of knowing, as in the Sanscrit *jñā*, the Greek *γινῶμαι*, Latin *gnoceo*, English *know*; the close relation of these two ideas being best seen in the Teutonic *kann* (can) and *kenne* (ken). Other and more complete illustrations of the metaphorical processes which, from means so poor and weak, produced the wonderful fabric of philosophic language, will be found in Professor Max Müller's *Lectures on Language*.

The ultimate conclusions to which the science of language may carry us are not on all points definitely ascertained. The original form of those primary roots which we call predicative is yet to be ascertained; and the philologists who advocate the onomatopoeic theory, which traces them to imitations of natural sounds, maintain on this point a sharp controversy with their opponents. (F. W. Farrar, *Chapters on Language*.) If their conclusions (which would not at all weaken the argument from the general ideas expressed in predicative roots) can be established, they would further prove that man was originally mute, while the evidence already at our command shows that he was unable during a long period to express more than the merest bodily sensations. Each stage in the growth of language marks the formation of new wants, new ideas, and new relations. 'It was an event in the history of man,' says Professor Max Müller, 'when the ideas of father, mother, brother, sister, husband, wife, were first conceived and first uttered. It was a new era when the numerals from one to ten had been framed, and when words like law, right, duty, generosity, love, had been added to the dictionary of man. It was a revelation—the greatest of all revelations—when the conception of a Creator, a Ruler, a Father of man, when the name of God was for the first time uttered in this world.' [Roots.]

The following genealogical table of the Aryan family of languages may serve to illustrate the remarks made in this article:—

LANGUAGE

LIVING LANGUAGES	DEAD LANGUAGES	BRANCHES	CLASSES
Dialects of India . . .	Prakrit and Pali ; Sanscrit, Modern and Vedic	Indic . . .
the Gipsies	Iranic . . .
Persia . . .	Paral, Pehlavi, Zend
Wales
Brittany	Cymric
—	Cornish	Celtic . . .
Scotland
Ireland	Gadhelic
Portugal
Spain
France . . .	{ Langue d'oïl } lingua vulgaris { Oscan	Italic . . .
Italy . . .	{ " d'oil } { Latin
Wallachia	{ Umbrian }
Albania	Illyric . . .
Greece . . .	Kouvé { Doric, Æolic	Hellenic . . .
Lithuania . . .	Attic, Ionic
Russia
Poland
Gerrmany . . .	Middle High German—Old High German
—	Gothic
England . . .	Anglo Saxon
Holland . . .	Old Dutch
Denmark
Sweden
Norway
Iceland

Northern division
Aryan family

A more complete table of the Aryan languages, together with genealogical tables of the Turanian and Semitic families of languages, will be found in Professor Max Müller's *Lectures on Language*, first series.

On the subject generally, see Max Müller, *Lectures on the Science of Language*, first and second series, wherein abundant references will be found to all the important philological works of recent writers. [TEUTONIC.]

Laniaries, Dentes Lanarii (Lat.). The long conical and sharp-pointed teeth which are placed next behind the incisors. They are also called *dentes canini* and *cuspidati*. They never exceed $\frac{1}{2}$ —1 in number in the Ferine Mammalia.

Lanius (Lat. *a butcher*). A Linnæan genus of Passerine birds, forming the typical family of the Dentirostral division of that order in the system of Cuvier. The birds of the family *Laniidae*, shrikes, or butcher-birds, are characterised by a strong compressed conical beak, more or less hooked, and emarginate near the point, as in the other Dentirostræ. The shrikes live in families, and fly irregularly and precipitately, uttering shrill cries; they build in trees, lay five or six eggs, and take great care of their young. They have the habit of imitating a part of the songs of such birds as live in their vicinity. The larger and stronger birds are predatory, and attack, slay, and devour smaller birds; whence the name *Butcher-bird*.

Lansium. This genus of *Miliacæ* yields the Lansia, Langsat, or Ayer-Ayer, a yellow fruit about the size of a pigeon's egg, highly esteemed in the East. The species *L. domestica* is a tree with imparipinnate leaves. Its wood is used by the Malays.

Lansquenets, Lansknechts (Ger. landknechte, *country men or lads*, or lanzknecht, from the *lance* or pike which they carried). The German infantry first raised by the emperor Maximilian to confront that of the Swiss, to-

wards the end of the fifteenth century. The lansknights were very irregularly armed, the greater part with pikes, but certain companies in every division had muskets. They were raised by voluntary enlistment, and their leaders passed with little reluctance into the service of any power which was willing to pay them. This infantry played a conspicuous part in the wars of Italy, in the first half of the sixteenth century, after which the name fell into disuse.

Lantern (Lat. *lunerna*). In Architecture, a drum-shaped erection, either square, circular, elliptical, or polygonal in plan, placed on the top of a dome, or on that of an apartment, to give light. [CUPOLA.]

Lantern, Magic. [MAGIC LANTERN.]

Lantern Wheel. In Mechanics, a kind of pinion having, instead of leaves, cylindrical teeth or burs, known as *trundles*, or spindles, in which the teeth of the main wheels act. The ends of the trundles being fixed in two parallel boards or plates, the lantern wheel has the form of a box, or a lantern, whence the name; it is much used in horology, but is now seldom employed in mechanics, for which purposes toothed wheels have been substituted for it.

Lanthanite. Native carbonate of lanthanum.

Lanthanum (Gr. *λανθάνειν*, *to escape notice*). A metallic substance discovered by Mosander in *Cerite*; it is associated with, and concealed as it were by, the oxide of cerium. The anhydrous oxide of lanthanum is of a brick-red colour: the hydrated oxide is white, and rapidly absorbs carbonic acid.

Lanyards (perhaps connected with the Fr. *lanière*, *a thong*). On Shipboard, short ropes used in making fast various articles; but more particularly in stretching, by means of deadeyes or blocks, other ropes, as the shrouds, stays, &c.

Laocon (Gr.). In Greek Mythology, a son of Antenor and priest of Apollo or Poseidon during the Trojan war. While he was

LAPAGERIA

engaged in sacrificing a bull to Poseidon, two enormous serpents, sent by Athena, in revenge for his having endeavoured to dissuade the Trojans from admitting the famous wooden horse within their walls, issued from the sea; and having fastened on his two sons, whom he vainly endeavoured to save, at last attacked the father himself, and crushed him to death in their complicated folds. (Virgil *Æn.* ii.)

This story has gained celebrity from its forming the subject of one of the most beautiful groups of sculpture in the whole history of ancient art. The composition is pyramidal, and represents Laocoon and his two sons writhing and expiring in the convolutions of the serpents. This famous group of sculpture, which was highly praised by Pliny, was discovered at Rome among the ruins of the palace of Titus, at the beginning of the sixteenth century; and afterwards placed in the Farnese palace, whence it found its way to the Vatican. It was executed by Polydorus, Agesander, and Athenodorus, the three celebrated artists of Rhodes.

Lapageria (after Josephine Lapagerie, the first wife of Napoleon Bonaparte). A beautiful genus of twining undershrubs from Chili, belonging to the *Philesiaceae*. *L. rosea*, with its great bell-shaped rosy-crimson lily-like flowers, is one of the most gorgeous creepers introduced for the ornamentation of our greenhouses.

Lapilli (Lat. *lapillus*, a little stone). Small volcanic cinders.

Lapis (Lat.). In Roman Antiquity, literally a stone; but the term was used among the Romans to signify a mile, at the end of which lapides or stones were erected with a mark thereon to show the distance from Rome. Hence the phrases *tertius lapis*, *centesimus lapis*, &c., for 3, 100, &c. miles; and sometimes even the ordinal number was used, with *lapidem* understood, as *ad duodecimum*—twelve miles distant. The Roman practice of indicating the distance of one place from another by the erection of stones has been borrowed by almost all the nations of modern Europe.

Lapis Causticus (Lat.). Caustic potash.

Lapis Divinus (Lat.). A compound of nitre, alum, and verdigris, melted together; camphor is sometimes added, and white vitriol substituted for verdigris. A portion of this fused compound dissolved in water formed a celebrated eye lotion; it was hence also called *Lapis ophthalmicus*.

Lapis Infernalis (Lat.). Fused nitrate of silver; often called *lunar caustic*.

Lapis Lazuli (Lat. *lapis*, and Arab. *azul*, heaven). A mineral of a blue colour, found in masses or nodules (generally in granite or crystalline limestone) mixed with felspar and Quartz, and often sprinkled with yellow grains of Iron Pyrites. It is a silicate of soda, lime, and alumina, together with a sulphide (probably of iron and sodium). Frequent use is made of it in mosaic and inlaid work, as well as for making vases and other costly ornaments; and when ground to a fine powder, and carefully

LAPLACE'S COEFFICIENTS

washed, so as to remove all foreign matters, it furnishes the valuable pigment known by the name of *Ultramarine*. A nodule of considerable size has been found in the basalt of Titterstone Cleve Hill in Shropshire; but Siberia, Persia, China and Bucharica are its chief sources. [LAZULITE.]

Lapis Lydius (Lat.). Lydian stone. A silicious slate, used as a *touchstone* for trying the quality of gold and silver by the colour of the streak.

Lapis Ollaris (Lat.). [POTSTONE.]

Lapis Specularis (Lat. from *speculum*, a mirror). The *Specular Stone* of the ancients generally signifies Mica, but sometimes Selenite or transparent Gypsum.

Lapithæ (Gr. *Λαπίθαι*). In mythical Geography, a people of Thessaly, chiefly known to us from their fabled contests with the Centaurs. The battle between the Centaurs and the Lapithæ has been described by Hesiod and Ovid with great minuteness.

Laplace's Coefficients and Functions. In the calculus of attractions, certain coefficients and functions which were first investigated in the *Mécanique Céleste*. They have their origin in the following considerations. If

$$u = [(x-x')^2 + (y-y')^2 + (z-z')^2]^{-\frac{1}{2}}$$

denote the reciprocal of the distance between two points (x, y, z) and (x', y', z') ; then the following partial differential equation will be satisfied identically:

$$\frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2} + \frac{\partial^2 u}{\partial z^2} = 0.$$

[POTENTIAL.] If polar coordinates be employed, then

$x = r \sin \theta \cos \phi$, $y = r \sin \theta \sin \phi$, $z = r \cos \theta$, and putting for brevity $\cos \theta = \mu$, the last equation becomes

$$r \frac{\partial^2 ru}{\partial r^2} + \frac{\partial}{\partial \mu} \left\{ (1-\mu^2) \frac{\partial v}{\partial \mu} \right\} + \frac{1}{1-\mu^2} \frac{\partial^2 u}{\partial \phi^2} = 0,$$

and u or

$$\left\{ r^2 + r'^2 - 2rr'[\mu\mu' + \sqrt{1-\mu^2}\sqrt{1-\mu'^2}\cos(\phi-\phi')] \right\}^{-\frac{1}{2}}$$

may be expanded in a series of the form

$$P_0 \frac{1}{r} + P_1 \frac{r'}{r^2} + \&c. \dots + P_i \frac{r'^i}{r^{i+1}} + \dots$$

Each coefficient P_i will be a determinate rational and integral function of μ , $\cos \phi \sqrt{1-\mu^2}$, and $\sin \phi \sqrt{1-\mu^2}$ of the i^{th} dimension in μ , and an exactly similar function of μ' , $\cos \phi' \sqrt{1-\mu'^2}$ and $\sin \phi' \sqrt{1-\mu'^2}$, whose greatest numerical value will be unity. These coefficients $P_0, P_1, P_2, \dots, P_i$ are called *Laplace's coefficients* of the orders 0, 1, 2, \dots, i respectively. Substituting the series for u in the last differential equation, it is easily seen that P_i satisfies the equation

$$\frac{d}{d\mu} \left\{ (1-\mu^2) \frac{\partial P_i}{\partial \mu} \right\} + \frac{1}{1-\mu^2} \frac{\partial^2 P_i}{\partial \phi^2} + i(i+1)P_i = 0;$$

LAPLACE'S THEOREM

an equation which has been integrated directly by Hargreave, Donkin, Boole, and others. (*Phil. Trans.* 1841 and 1857; Crelle's *Journal* and *Cambridge and Dublin Math. Jour.*) All functions of μ and ϕ which satisfy the last equation, known as *Laplace's equation*, are termed *Laplace's Functions*. Amongst other useful properties of such functions are the following:

1. Q_i and R_i being two Laplace's functions,

$$\int_0^i \int_0^i Q_i R_i d\mu d\phi = 0$$

whenever i and i' are different integers.

2. Any function of μ , $\cos \phi \sqrt{1-\mu^2}$ and $\sin \phi \sqrt{1-\mu^2}$ which does not become infinite between the limits of the above integrals can be expanded in one, and only in one, series of Laplace's functions. If

$$F(\mu, \phi) = F_0 + F_1 + \dots + F_i \dots$$

represent this expansion, then

$$F_i = \frac{2i+1}{4\pi} \int_{-1}^1 \int_0^{2\pi} F(\mu', \phi') P_i d\mu' d\phi'.$$

The writers on Laplace's functions are very numerous. It will suffice here, however, to mention the two most recent special works on the subject. The one is the *Treatise on Attraction*, *Laplace's Functions*, and the *Figure of the Earth*, by Archdeacon Pratt (London 1861); the other the *Handbuch der Kugelfunctionen* by Heine (Berlin 1861).

Laplace's Theorem. [LAGRANGE'S THEOREM.]

Lapping. In Artillery, wearing away by friction a very small portion of the surface of the lands of a rifled gun, in order to ease the passage of the shot.

Lapse (Lat. *lapsus*, a slip). In Ecclesiastical Law, the omission of a patron to present a clergyman to a benefice within six months after its being void; in which case the benefice is said to be void, and the right is lost to the patron. In England the right of presentation then accrues to the bishop, and to the sovereign by the neglect of these; and in Scotland it devolves on the presbytery.

Lapwing. The name of a native species of the genus *Vanellus*, dismembered by Bechstein from the *Tringa* of Linnaeus. [VANELLUS and TRINGA.] The lapwing or pee-wit (*Vanellus cristatus*, Bechst.) is an inhabitant of this country, and subsists chiefly on worms and the animalcules of the seashore, which it frequents in great numbers. The female makes a simple nest by scraping together a little dry grass, and deposits thereon four eggs, of a dirty olive colour spotted with black. The young birds are covered with a thick down when hatched, and soon begin to run about: at the approach of danger they squat down, and the parent, by a curious instinct, endeavours to attract the attention of the intruder, and draw him away from the spot, by fluttering about with cries of inquietude, or even running along the ground as if lame. In October the lapwings are fat, and in good condition for the table: their eggs are considered a great delicacy.

LARGO

Laquæar (Lat.). In Architecture. [LACUNÆ.]

Lararium (Lat.). In Ancient Architecture, the apartment in which the lares or household gods were deposited; it also frequently contained statues of the proprietor's ancestors.

Larboard (Ital. *quello bordo*, *that side*, contracted in speaking to 'lo bordo). The former term for the left-hand side of a ship to a person standing on it, whose face is turned towards the head. The other side is called the *starboard*; and as, from the resemblance of sound, larboard and starboard were often confounded, the word was officially abolished a few years ago, and *port* substituted arbitrarily for it. [PORT.]

Larceny (Fr. *larcin*, from Lat. *latrocinium*, *theft*). In Law, a species of felony, distinguished formerly into simple and mixed: the latter of which was the taking of goods and chattels from the person, or from the house, if above the value of twelve-pence. But this distinction was abolished in 1828. Larceny is the felonious and fraudulent taking and carrying away of the goods and chattels of another. Thefts of things affixed to the freehold, if forming part of what is termed real property, are not larceny at common law; but many offences of this description have been brought within the character of larceny by enactment. Robbery, breaking into and stealing in a dwelling-house, if in the daytime, piracy, &c., are species of mixed larceny. A receiver of stolen goods is indictable either for a substantive felony, or as accessory to the theft or robbery. The law on the subject of this and cognate offences is now consolidated by 'The Larceny Act 1861.' [LAW, CRIMINAL.] The punishment of simple larceny is three years' penal servitude, or two years' imprisonment.

Larch (Lat. *Larix*). The Common Larch is *Abies Larix*; the American Larch, *Abies pendula*, the Tamarack of the Canadians. [ABIES.]

Larderellite. A native borate of ammonia found at the lagoons of Tuscany, and named after count de Larderel.

Lardite. A kind of Chinese *Figure-stone* or Agalmatolite, named after M. Lardi.

Lares (Lat.). Domestic deities of the Latins, who were probably regarded as the souls of the deceased ancestors of a family. Their worship, however, was not confined to private houses; as there were lares of the city, the country, roads, &c. [PENATES.]

Large (Ital. *largo*). In ancient Music, a character representing the greatest measure of musical quantity; one large containing two longs, one long two breves, one breve two semi-breves.

LARGE. In Sailing, this term is applied to a wind abaft the beam, but not straight astern. *To sail large* is to sail on a large wind.

Larghetto (Ital. *dim. of largo*). In Music, a movement a little quicker than *largo*.

Largo (Ital.). In Music, a direction for the time, or rather the style, in which a piece of music is to be performed. It is generally un-

LARIDÆ

derstood to mean *slow*, but the real meaning is *wide, roomy*; a figurative expression for a broad expressive style [ALLUO.]

Laridæ. A family of swimming birds, having the gull (*Larus*) as the type. [LARUS.]

Larix (Lat. *the larch*). The name under which some botanists separate the Larch from other species of *Abies*.

Larixnic Acid. A volatile crystallisable acid, contained in the bark of the larch.

Lark (A.-Sax. *laferc*; Scotch, *lavrock*: as hawk from *hafoc*). The common name of the native species of the genus *Alauda* of Linnæus; of which one, the *Alauda arvensis*, is distinguished as the sky-lark or lavrock; the other, *Alauda campestris*, Linn., is called the field-lark. As the species of the present genus differ from most other insectorial birds in resting habitually and sleeping upon the ground, their feet present a singular but simple modification, which at the same time beautifully adapts them to their office of supporting the superincumbent body on a flat surface: it consists in the extreme elongation in an almost straight line of the claw of the hinder toe, which is, at the same time, proportionally robust: thus the plane of support is extended at the expense of the prehensile faculty, which the habits of the lark render of little or no value to it.

The sky-lark is universally admired for the power and melody of its song, and for the beautiful associations inspired by the circumstances under which its notes are most richly poured forth, viz. while soaring aloft to greet the rising sun. It ascends in the air almost perpendicularly, by successive flights, to an elevation at which its song becomes inaudible: its descent is generally oblique. The female builds her nest on the ground, and lays four or five eggs, which are of a greyish brown colour marked with darker spots: she sits about fifteen days, and usually rears two broods in the year. This prolific species is granivorous, and in the winter large flocks congregate together; they are very fat at this season, and are captured in great numbers for the table. [ALAUDA.]

Larkspur. The common name for the plants referred to the genus *Delphinium*. They belong to the order *Ranunculaceæ*, and are for the most part of ornamental character. [DELPHINIUM.]

Larmier (Fr.). In Architecture. [CORONA.]

Larus (Lat.; Gr. *λαρος*). A Linnæan genus of aquatic birds belonging to the longipennate division of palmipeds in the system of Curvier, and now raised to the rank of a family comprising several subgenera. The *Laridæ*, or gulls, are characterised by their compressed elongated pointed bill, of which the superior mandible is curved downwards near the end, and the inferior forms a salient angle beneath. The nostrils, placed near its middle, or a little more forwards, are long, narrow, and form a complete transverse perforation: the tail is ample, and sometimes pointed. (*Ictria*.) The gulls are common and numerous on the seacoast, and feed on the different animal sub-

LASCARS

stances which are left on shore or float down with the ebbing tide. The black-headed gull (*Larus ridibundus*, Linn.) breeds on the marshy edges of rivers or fens; the female makes her nest among the reeds and rushes of heath or dried grass, and lays three or four eggs of an olive-brown colour spotted and streaked with dusky red. When the young are able to accompany the parents, they all resort to the seashore. The other species of gulls build for the most part in the sand or the clefts of rocks.

Larva (Lat. *a spectre*). A Metabolian insect in its first stage after exclusion from the egg is so called, because its real form is, as it were, masked: the same term is also applied to those reptiles which undergo a metamorphosis, as the frog, when at a corresponding period of existence. The term *grub* is applied to the larvæ of many insects; while that of *caterpillar* is most frequently reserved for the *Lepidoptera*.

Larvæ. Spectres of the deceased were so termed by the Romans. They were held to be mere empty forms or phantoms, as their name indicates, yet endowed with a sort of existence resembling life, since they were to be propitiated by libation and sacrifice. The larva of Caligula, according to Suetonius, was often seen in his palace after his decease. The larvæ are described by Seneca, and often represented in paintings and on gems under the figure of a skeleton; sometimes under those of old men, with shorn locks and long beards, carrying an owl on their hands.

Larvipara (Lat. *larva*, and *pario*, *I bring forth*). Those insects are so called which bring forth larvæ instead of eggs, the latter being hatched in the oviduct.

Laryngitis. Inflammation of the larynx. The symptoms are hoarseness, sense of suffocation, great anxiety and restlessness, and spasmodic difficulty of deglutition. The acute form of the disease sometimes terminates fatally in twenty-four hours. Chronic inflammation of the larynx is not an uncommon complaint, and often a very troublesome one; requiring for its relief strict attention to the general health and the careful use of counter-irritation. The acute form of the disease requires local depletion and general antiphlogistic treatment.

Laryngophony (Gr. *λαρυγγόφωνος*, *sounding from the throat*). The sound of the voice as heard by applying the stethoscope over the larynx.

Laryngotomy (Gr. *λαρυγγοτομία*). The operation of making an opening into the larynx. [ΒΡΟΧΟΤΟΜΙΑ.]

Larynx (Gr. *λάρυξ*). The upper extremity of the trachea. It is a cartilaginous cavity, the superior opening of which is called the *glottis*. Its various parts, anatomically considered, are extremely complex and intricate, especially in reference to its construction and physiology as the organ of voice.

Lascars. The name popularly given to the native Malayan sailors, many of whom are in the service of our mercantile navy.

LASER

Laser (Lat.) or **Cyrenaicum**. *Asa dulcis*. A gum resin which was greatly esteemed by the ancients, and obtained from the north of Africa. It is described by Dioscorides (lib. iii. c. 48); and, under the name of *silphion*, by Theophrastus. Different names were given to different parts of the plant which affords it, the term *laser* being exclusively applied to the inspissated juice. From the representations of the plant upon the coins of Cyrene, it appears to have been one of the *Umbelliferae*, and according to Lindley (*Flora Medica*, p. 52) was in all probability obtained from *Thapsia Silphion* or *garganica*.

Lasionite. A kind of Wavellite, found in slender silky fibres at the mine of St. Jaques, near Amberg, in Bavaria.

Lasso (Span. from Lat. *laxus*, *loose*). A rope furnished with a noose at one end. It is much used in Australia and America for catching wild cattle. In the British cavalry, ten men per troop are supplied with the lasso, in order that they may, on emergencies, be available for purposes of draught.

Last. In Commerce, a measure of uncertain quantity, varying in different countries and with respect to different articles. Generally, however, a last is estimated at 4,000lbs. (*Commercial Dictionary*.)

Lastage. Ballast or lading in a ship.

Lastrea (after M. de Lastrea, of Chatelleraut). The modern genus of Ferns of which the Male Fern, *L. Filix-mas*, is the type. It is separated from other Aspidiaceae Ferns by its free veins and kidney-shaped sori, owing to which latter character some botanists prefer to place it in *Nephrodium*, in which, however, in a more limited sense, the veins are united. It is a very extensive genus found in all parts of the world.

Lasurite. Blue carbonate of copper. [CHESSYLITE.]

Latania (Latanier, its Bourbon name). A genus of African Palms, with fan-shaped leaves, and forming trees twenty or thirty feet high. The pulp of the fruit of *L. Commersonii*, though disagreeable in flavour, is eaten by the negroes. This species is a native of the Mascaren Islands, and is often cultivated in our hothouses.

Lateen Sail (Ital. *latina*, *large* or *broad*). A triangular sail having its upper edge fastened to a long yard much inclined to the horizon. It is used on kebecs and other vessels navigating the Mediterranean.

Latent Heat (Lat. *lateo*, *I lie hid*). When heat is applied to a solid, the temperature of the latter rises until it begins to melt; but even if the application of heat be continued uninterruptedly, a thermometer placed in contact with the melting solid remains stationary until complete liquefaction has taken place. The same phenomenon is observed when a solid or liquid is converted into vapour by heat. During liquefaction or vaporisation a large amount of heat is absorbed without rendering the body hotter, and hence the heat so disappearing has been termed *latent heat*. In such cases the

LATH

heat thus said to be rendered latent is consumed either in separating the atoms of the body from each other or in moving them into new positions. It, therefore, no longer exists as *heat*; but when the vapour is condensed or the liquid solidified, the amount of heat which has thus been consumed is re-generated. (*Heat as a Mode of Motion*, by Prof. Tyndall, p. 147.)

Lateral Operation. A Surgical term applied to one of the methods of cutting for the stone.

Lateran. A church at Rome, the Pope's see, and the metropolitan of the whole world, dedicated to St. John Lateran. The name is derived from the Roman family of the Laterani, who possessed a palace on this spot, which was seized by Nero, and became from his time an imperial residence. The Lateran palace was given by Constantine to the popes (Milman's *Hist. of Christianity* ii. 361), who continued to inhabit it until their retirement to Avignon, when it was exchanged for the Vatican. The building was then converted into a church. Eleven councils have been held in the Basilica of this name (hence styled Lateran councils in ecclesiastical history), of which four are considered by Roman Catholics to be general. The last of these (or the twelfth general, according to the same computation) is the most celebrated. It was held in 1215 by Innocent III., and is principally famous as establishing the Roman Catholic doctrine of the Eucharist, using for the first time the term *transubstantiation* for the change of the elements. This council was convoked on the occasion of the heresy of the Albigenses, and its exposition of the Catholic faith is directed principally against them. It established also some canons for the maintenance of discipline among the clergy, and that (*omnis utriusque sexus*) which enforces confession and communion upon all the faithful at least once a year.

Lateritious (Lat. *lateritius*, from *later*, a brick). This term is applied to the reddish sediment which is often deposited by the urine.

Latex (Lat.). A coagulable sap which circulates in the vessels of the laticiferous tissue of plants. The term is extended to any kind of viscid fluid conveyed in the laticiferous vessels, whether opaque or not.

Lath (Ger. *latte*). In Architecture, a thin cleft piece of wood used in slating, tiling, and in plastering. Two sorts of laths, single and double, are known amongst London builders, and both of them are made out of Baltic fir; the former being barely a quarter of an inch in thickness, the latter being three-eighths of an inch; the foreign laths are usually split out of oak, and are made of various thicknesses. Pantile laths are long square pieces of fir or oak, on which the pantiles hang. The term has also lately been applied to the wrought-iron strips that serve to fasten the slates or the sheets of metal on a roof; or to the strips that support the filling-in part of a fireproof floor.

Lath Floated and Set Fair. In Archi-

LATH

ture, two-coated plasterer's work; the first is called *laying*, and is executed without scratching, except with a broom. When used on partitions and walls, this kind of work is generally coloured; when on ceilings, it is white.

Lath Plastered, Set, and Coloured. In Architecture, the same as lath laid, set, and coloured in addition; the same definition may be extended to the work called lath pricked up, floated, and set fair for paper, excepting that it receives an additional coating—the pricking-up coat essential for procuring the even surface that is required for paper.

Lathe. An Anglo-Saxon territorial division, of which the etymology is uncertain. Kent is the only county divided into lathe, each of which contains four or five hundreds. Each was originally under the jurisdiction of a lathe-reeve, subordinate to the sheriff of the county.

LATH. An engine in which rotary motion is given to the object proposed to be turned, the tool intended to act upon it being held or fixed in any requisite position. It is much used, and is, in the hands of the best makers, a very complicated and ingenious piece of mechanism. The old lathes were worked by the foot; but in modern works, the head-stocks are made so large that it is necessary to put them in motion by a steam engine. A good lathe consists of: 1. the frame; 2. the head-stocks, which bear also the differential pulleys, to allow the velocity of the motion to be changed; 3. the rest for the tools; and 4. the corresponding differential pulleys upon the shaft communicating motion; the foot motion would be comprised under the frame.

Latroæa (Gr. λαθραῖος, *concealed*). A curious genus of *Orobanchaceæ*, called Toothwort. The English name arose from the root, which is parasitic on the roots of trees, and is branched, and clothed with numerous fleshy scales, resembling teeth. On this ground the old herbalists considered it a specific for toothache.

Lathyrus (Gr. λάθυρος, *a vetchling*). A considerable genus of *Leguminosæ*, one of the most familiar of which is *L. odoratus*, the Sweet Pea of the gardens. Several other species are cultivated for ornamental purposes. *L. sativus* is grown in the south of Europe under the name of Gesse, or Jarosse: its seeds are eaten in the same way as the chick pea, but are of a superior quality. The whole plant is sometimes cut for forage. The tuberous roots of *L. tuberosus*, not uncommon in cornfields in various parts of Europe, and lately found in Essex, are eaten, boiled or baked, in countries where they are abundant. *L. Aphaca*, which has leaf-like stipules, but no leaflets, and *L. Nissolia*, which has neither leaflets nor stipules, but flattened grass-like leaf-stalks, are two rare annual native plants.

Latialite (from Latium, the old region of the Latins, in Italy). A synonym for Haüyne.

Laticiferous Vessels. One of the elementary tissues of plants, probably a modification.

LATITUDE

tion of cellular tissue, and consisting of tubes in which Latex is conveyed.

Laticlave (Lat. latus clavus). The broad stripe which Roman senators and patricians were privileged to wear on their robe.

Latin Church. In Ecclesiastical History, a name applied to the church of Rome and the churches in communion with it, as distinguished from the Greek or Eastern or Orthodox communion. As contrasted with the latter, the Latin Church was long distinguished by a less subtle and refined theology, and by greater vigour of action. For a full examination of the characteristics of these two great religious bodies, see Milman, *History of Latin Christianity*, also *Edinburgh Review*, January 1858, p. 64, &c.

Latissimus Dorsi. In Anatomy, a broad muscle of the back which pulls the os humeri downwards and backwards, and assists in its rotatory motion.

Latitude (Lat. latitudo, *breadth*). In Geography, this term signifies the distance of a place from the equator, expressed in degrees of the earth's circumference; or it is the angle which a line perpendicular to the horizon of any place makes with the plane of the earth's equator. In Astronomy, the term *latitude*, as applied to a celestial body, has a different signification, and means the distance of the body, or rather the place of the body, from the ecliptic, or plane of the earth's orbit. The term *declination* is applied to denote the angle corresponding to terrestrial latitude; namely, the distance of a star or planet from the plane of the earth's equator. This double signification of the term is unfortunate, as it tends to create a confusion of ideas; but having been introduced by the early astronomers, and being ingrafted into every existing work on the science, it is now too late to substitute another word in its place.

Latitude and longitude being the coordinates by which the positions of places on the terrestrial surface are defined, their determination forms a most important application of astronomy.

In order to give an idea of the methods of finding the latitude of a place, or of a ship at sea, it is necessary to recall some of the elementary properties of the sphere. Let *H H'* be the horizon of a spectator placed at *C*; *C P* the direction of the axis of the earth; and *C Z* the direction of the zenith, or perpendicular to the horizon. Let *C E* be drawn perpendicular to *C P*, in the plane determined by the straight lines *C P* and *C Z*, or the plane of the meridian; then *C E* is the intersection of the planes of the equator and meridian; the semi-diameter of the earth being neglected as infinitely small in comparison with the distance of the celestial concave, to which *C P*, *C Z*, and *C E* are supposed to be prolonged. Hence *Z* is the zenith and *P* the elevated pole.

Now, by the definition, the angle *E C Z* is the latitude of *C*; and it is this angle, therefore,

LATITUDE

which is to be determined. The observer always knows his zenith by the direction of the plumb-line; but there is no visible mark in the heavens by which he can at all times determine the place of the equator, or the position of E in the meridian, or even the meridian itself. But the angles EOP and ZCH being each right angles, ECZ is equal to PCH ; that is to say, the latitude of the place is equal to the height of the visible pole. Now the pole is a fixed point in the heavens, and its position (in the northern hemisphere) is indicated nearly by a star, called the pole star, or a *polaris*, which describes a small circle within $1^\circ 40'$ of it. By observing, therefore, the height of the pole star at any place, an approximation to the latitude will be obtained within $1^\circ 40'$ of its true value. But this approximation is very far from being sufficient for any useful purpose; it is therefore to be corrected by means of a table called the 'correction for pole star.'

The places of the principal stars being given in the existing catalogues, the observed altitude of any one of them at the time when it passes the meridian will give the latitude of the place. Let S be a star on the meridian, and SP its polar distance in the catalogue, and let its altitude $H'S$ be observed; then $H'S$ being known, SZ , the zenith distance, is also known; and SP being also known, we have $SP - SZ = ZP$, the complement of the latitude. In like manner, the latitude may be found by observing the meridional altitude of the sun, or moon, or a planet, the declinations of all these bodies at any time being known. Various methods have been given for determining the latitude by observations of the heavenly bodies; but though all the methods are equally good in theory, they are not all equally practicable, and some of them give results attended with much greater uncertainty than others. The following are those which are chiefly employed.

1. By observing the altitude or (which comes to the same thing) the zenith distance of a star on the meridian. This is the simplest in practice, requiring only a single observation, and no other correction than for refraction. It is accordingly generally employed for common geographical purposes. When the sun or planets are the bodies observed, corrections must also be applied for the semi-diameter of the body and for the parallax. At sea the bodies selected are the sun and moon, the observation of a star or planet being difficult. To know when a heavenly body is on the meridian, it is necessary to have a pretty accurate knowledge of the time; but it may be remarked that near the meridian the altitude varies very slowly, and therefore a small error in respect of the time does not much affect the result.

2. By the altitudes of circumpolar stars (those which never go below the horizon of the place) at their upper and lower transits. If the altitude of a star on the meridian is observed both above and below the pole, the sum of the two altitudes is equal evidently to twice the height of the pole, or twice the latitude. The

only correction required is for refraction, which is not the same in the two observations.

3. The latitude may also be found by observing the greatest and least meridian altitudes of the sun in the course of a year. The sum of the altitudes of the sun at the summer and winter solstices is equal to twice the height of the equator, or twice the complement of the latitude; but this method requiring observations to be made at an interval of six months, is seldom employed, excepting in fixed observatories.

4. All the preceding methods suppose the body observed to be on the meridian; but this condition, though it renders some calculation unnecessary, is not indispensable. The latitude may be determined by the observed altitude of a body out of the meridian; and indeed with more certainty, because several observations may be made successively, the mean of which will give a surer result than a single meridional observation. Let P be the pole, S the place of the star or planet, and SZ its observed zenith distance, or the complement of its observed altitude. In the triangle PSZ , PS , the polar distance of the star, is known; SZ is given by observation; and the hour angle ZPS is given, because the time of the observation is supposed to be known; therefore PZ , the co-latitude, may be found by the solution of a spherical triangle. This method, however, can only be successfully applied by observing near the meridian, unless the exact time of observation is known; and some artifices of analysis are required to adapt the trigonometrical formulæ to calculation.

Another method of finding the latitude is the one called Sumner's method. When one altitude only can be taken, the place of the observer may be assumed to be on a line, which is found as follows. With the estimated latitude of the ship, the altitude, and declination, and by means of the chronometer, showing Greenwich mean time, calculate the longitude. Mark the spot on the chart corresponding to this latitude and longitude. Assume another latitude a few degrees different from the former, and find the longitude as before. Mark the spot on the chart corresponding to this latitude and longitude. Join the two spots thus found, and the place of the ship will be on or very near to the line, or the line produced. If another altitude could be taken an hour or two afterwards, and two spots determined in like manner, the line joining them will intersect the other line on the chart in or near the true place of the ship, and thus the position of the ship will be found very nearly. The estimated latitudes should, if possible, be taken one greater and one less than the true, and within a few degrees of each other; a small diagram or chart bounded by the two parallels of latitude passing through the estimated latitudes may be easily constructed, and the place of the ship indicated thereon by the intersection of the two lines found as above. This method is fully described in Mr. John Riddle's *Navigation*.

LATITUDE

5. The method in most general use for finding the latitude by observations off the meridian is the one known as 'Inman's Double Altitude.' This consists in taking the altitudes of the same heavenly body, or of different heavenly bodies, and noting the interval or elapsed time between the observations: the latitude may then be computed by the application of the common rules of spherical trigonometry.

6. The last method which we shall notice for finding the latitude is one that has been proposed by Bessel, and consists in observing the eastern and western passages of a star through the prime vertical; that is, the vertical plane at right angles to the meridian. When a transit instrument is adjusted to move in this plane, and consequently has its horizontal axis in the direction of the meridian, all the stars which pass the meridian between the zenith and equator will twice enter the field of the telescope. Now let t be the time of the eastern transit, t' the time of the western transit, δ the declination of the star, ϕ the latitude, and P the diurnal arc corresponding to the time $\frac{1}{2}(t-t')$; then the formula by which the latitude is determined is

$$\tan \phi = \frac{\tan \delta}{\cos P}$$

The advantages of this method are, that the observations may be made with a portable transit instrument, which can easily be oriented by means of the circumpolar stars; a small error in the adjustment will produce no sensible error in the result if the stars observed pass near the zenith; the observations are altogether independent of errors in the division of the instrument; and in determining differences of latitude, errors of declination are also eliminated by observing the same stars at all the stations. It is therefore a very convenient method for use in a trigonometrical survey.

Latitude on the Sphere or Reduced Latitude. In consequence of the whirling motion of the earth about its axis, the parts of the equator which have the greatest velocity acquire thereby a greater distance from the centre than the parts near the poles. By actual measurement of a degree of latitude in different parts of the earth, it is found that the equatorial diameter is larger than the polar diameter by about twenty-six miles, the former being about 7,924 miles, the latter about 7,898 miles, and that the form of the earth is that of an *oblate spheroid* resembling the annexed figure, in which PP_1 is the axis, and EQ the equator. It is usual, however, in drawing the figure of the earth, to exaggerate its ellipticity: this is done for the sake of drawing the lines about the figure with greater clearness, for if it were constructed according to its true dimensions the line PP_1 (being only about the $\frac{1}{305}$ th part of itself less than EQ) would appear to the eye of the same length as EQ , and we should see that the figure more nearly resembling the earth would be a sphere. The true latitude of a point A is the angle formed

LATTICE-LEAF

by AG , a perpendicular drawn to the earth's surface at A with the plane of the equator EQ : thus AGQ is the true latitude of A . The *reduced* or *central* latitude of A is the angle formed by AC , a line drawn from A to the centre C of the earth with the equator. Thus ACQ is the *reduced* latitude of A , or the latitude considering the earth as a sphere

The difference between the true and reduced latitude is not great; it is, however, of importance in some of the problems in nautical astronomy. The value of this correction for different latitudes has accordingly been calculated, and forms the nautical table called the *correction for the spheroidal figure of the earth*. (For the analytical investigation of this correction, see *Jeans' Navigation*.)

Latitudinarians. In Ecclesiastical History, a class of English divines in the reign of Charles II., who were opposed alike to the high tenets of the ruling party in the church, and to the fanaticism which then distinguished so many of the Dissenters. They were, of course, the objects of much attack; and one of their number, Fowler, bishop of Gloucester, explained their principles in his treatise entitled '*The Principles and Practice of certain modern Divines of the Church of England vulgarly called Latitudinarians, truly represented and defended, by way of Dialogue*, 1670.' Henry More and the other Platonising divines of the time were sometimes comprehended under this appellation. The word has been since very generally used to designate those who hold opinions at variance with the more rigid interpretation of Scripture and church traditions, or merely as a term of party vituperation.

Latona. [MINERVA.]

Latris (Gr. *λατρεία*, *hired service*). In Roman Catholic Theology, this term is applied to the worship of God, the adoration paid to the saints being distinguished by the name *dulia* (Gr. *δουλεία*, *slavery*), while that which is directed to the Virgin is exclusively known as *hyper-dulia*, or an excess of *dulia*.

Latrobeite. A variety of Anorthite, found, of a pale red colour, in Amittok Island, on the coast of Labrador. It is a hydrated silicate of alumina, peroxide of iron, lime, potash and magnesia. Named after the Rev. C. J. Latrobe, by whom it was first brought to this country.

Latten (Fr. *laiton*). Brass or bronze. Tinned iron is also sometimes called *latten*.

Latter-day Saints. [MORMONISM.]

Lattice-leaf. [OUVRANDRA.]

LATUS RECTUM

In the Conic Sections, the double of the ordinate at a focus. [CONIC SECTIONS.]

Laudanum (of uncertain derivation). Different preparations of opium have been so termed: the tinctures used formerly to be called *liquid laudanum*.

Laudicomi (Lat.). Among the Romans, persons who (like the modern claqueurs in France, or the puffers in England at auctions) attended the performance of plays and the delivery of orations, in order to raise or to join in the acclamation.

Lauds (Lat. *laudes, praises*). In the Roman Catholic Church, the prayers formerly used at daybreak, between those of *matins* and *prime*. In later times they have become generally confounded with *matins*.

Laughing Gas. [NITROUS OXIDE.]

Laumontite. A variety of zeolite, named after Gillet-Laumont. It crumbles when exposed to air in consequence of loss of water. It is a silicate of alumina and lime with sixteen per cent. of water.

Launch (Fr. *lancer, to hurl out*). The putting of a new vessel into the water. When the vessel is to be launched, a frame called *cradle* is built under her, thus: At about one-third of the extreme half-breadth are laid, on each side of the keel and parallel to it, long pieces of planed timber, forming, as it were, two keels under the principal portion of the vessel. On these are placed vertical timbers meeting the ship's bottom, and maintained from slipping outwards by a strong plank or ribband. This apparatus, which is the cradle, rests on each side upon a platform sloping to the water five-eighths of an inch in one foot; these platforms are called *the ways*, and are planed and greased. The blocks on which the keel was laid being removed with the shores, the vessel rests on the cradle, which is kept from sliding down by a small piece or bar of wood fixed to it lying nearly horizontal, abutting against a place in the ways called the *dog shore*, which being struck downwards falls, and the vessel slides down into the water. When afloat, the cradle, which was only kept together by the ship's weight, breaks up, and the detached pieces are recovered by boats.

LAUNCH. The largest boat carried by a man-of-war, and occasionally provided in very large vessels with guns and a screw engine to enable it to penetrate rivers.

Laura (Gr.). A name applied to the enclosure of a monastery in the Greek or (Orthodox) Eastern Church. The well-known *lauras* in Palestine, &c. were collections of cells in which hermits lived, in strict seclusion, but without a common monastic rule.

Lauraceæ (Laurus, one of the genera). A natural order of arborescent Exogens of the Daphnal alliance, inhabiting the cooler parts of the tropics and some temperate countries. They are distinguished from all other incomplete apetalous Exogens, excepting *Atherospermaceæ*, by the peculiar dehiscence of the

LAURENTIAN ROCKS

anthers, which open in consequence of the face of the valves rolling back; and from that order by the ovules being pendulous, not erect. The species are generally tonic and stimulant. Cinnamon and Cassia are the produce of some, Camphor of others, and the Common Sweet Bay (*Laurus nobilis*) is a frequent instance of the order in the northern form. A few are so aromatic that their seeds have been used as substitutes for nutmegs.

Laureate (Lat. *laureatus*). Literally, crowned with laurels. It was from some traditional belief respecting the coronation of Virgil and Horace with laurel in the Capitol (of which, however, no record is extant) that the dignity of poet laureate was invented in the fourteenth century, and conferred on Petrarch at Rome by the senator or supreme magistrate of the city. It was intended to confer the same honour on Tasso, who, however, died on the night before the proposed celebration. In 1725 and 1776 it was granted to two celebrated improvisatori, the Signor Ruffetti and the Signora Morelli, better known by the name of Corilla. [IMPROVISATORI.] In most European countries the sovereign has assumed the privilege of nominating a court poet with various titles. In France and Spain these have never been termed poets laureate; but the imperial poet, or Poeta Cesareo, in Germany, was invested with the laurel. In England traces of a stipendiary poet royal are found as early as Henry III., and of a poet laureate by that name under Edward IV. Skelton, under Henry VII. and Henry VIII., was created poet laureate by the universities of Oxford and Cambridge, and appears to have held the same dignity at court; but the academical and court honour were distinct until the extinction of the university custom, of which the reign of Henry VIII. exhibits the last instance.

Royal poets laureate are supposed not to have begun to write in English until after the Reformation. The office was made patent by Charles I., and the salary fixed at 100*l.* annually, with a tierce of Spanish Canary wine. Under Queen Anne it was placed in the control of the lord chamberlain. In the reign of George III. the annual tierce of wine was commuted for an increase of salary, and at the close of the same reign the custom of requiring annual odes from the lord chamberlain was discontinued.

Laurel. The common name for *Laurus*. The Cherry Laurel, or Common Laurel of the gardens, is the *Cerasus Laurocerasus*.

Laurencia (after M. de la Laurencie, a French naturalist). A genus of rose-spored *Algæ*, the type of the order *Laurenciucæ*. It contains some of our commoner seaweeds, as *L. obtusa* and *pinnatifida*, the former of which forms the greater part of what is now sold as Corsican Moss, and the latter is sometimes eaten under the name of Pepper Dulse.

Laurentian Rocks. In Geology, an important group of rocks, deriving its name from the river St. Lawrence, near which they are

LAURIN

developed. These rocks are anterior to those generally recognised as the oldest Silurian and Cambrian strata known in the British Islands. They are, however, believed to be represented by some examples of gneiss and slate in Scotland. Other contemporaneous series will, no doubt, be discovered. Among the Laurentian rocks of Canada very singular indications of the existence of organic bodies have been detected in Serpentine, Epidote, and other magnesian portions of the metamorphosed rock. Of the organic origin of these indications there can be little doubt; but it is not so clear to what group of organisms they may be referred. In appearance they remind the naturalist of the *Rudista*, a group of which, however, very little is really known. They resemble *Foraminifera* in structure, but their size is gigantic. Some naturalists have referred them to the *Spongiadæ*. They have been described by Dr. Carpenter and others under the name *Fozoon canadense*.

Laurin. A fatty matter of an acrid taste, contained in the berries of the common laurel.

Laurostearic Acid. One of the fatty acids of the Bay berry.

Laurus (Lat.). The typical genus of *Lauraceæ*, represented by the Bay or Noble Laurel. The branches of the Bay were used to form the crowns placed on the heads of the heroes of antiquity, and on the statues of the gods. The Bay is in this country an evergreen shrub with aromatic leaves, used on account of their agreeable flavour. Oil of Bay, an external stimulant, is expressed from the fruit.

Lava (from Lat. *lavare*, as being washed up). The molten matter poured out from active volcanoes in a fluid state. Although the word admits of clear definition, the mineral produced is often extremely different in different places. Thus when lava is erupted into the air, the upper part is full of air bubbles, and resembles a coarse ash. It is then called scoriaceous, or simply *scoria*. Not unfrequently similar scoriæ will be found at the bottom of a flood of lava where a thin stream has first come in contact with uneven and damp earth. Below the scoriaceous surface the lava is more compact, and where it has cooled more slowly and under greater pressure, it is found to have assumed a different aspect. The more compact and deeper parts of a lava current are often distinctly porphyritic, while the parts near the surface are sometimes like glass. [OBSDIAN.]

Lavas differ in composition, but on the whole there is a general similarity in many respects between the lavas of different countries and distant times. The same laws would seem to have always acted in reference to their formation.

Lava poured out under water assumes a different appearance from that which has been erupted in the air. It is more compact, and resembles basalt. [BASALT and VOLCANO.]

Lavandula. A genus of *Labiata*, containing two well-known officinal plants, *L. vera*, the common Lavender, and *L. Spica*,

LAW

which yields oil of Spike; the latter is somewhat the larger of the two. Lavender is an undershrub, with linear grey leaves and close spikes of bluish flowers, from which latter by distillation the essential oil of Lavender is procured. Preparations of Lavender are used both in perfumery and medicine. The oil of Spike, which has a less agreeable perfume, is used by painters on porcelain, and by artists in the preparation of varnishes.

Lavender. [LAVANDULA.]

Lavendulane. An amorphous mineral, of a lavender-blue colour, from Annaberg in Saxony. It is a mixture of arsenates of cobalt, nickel, and copper.

Laver (as it is otherwise called *sea liverwort*, the word looks like a corruption of *liver*). The *Porphyra vulgaris*, esteemed by some as a delicacy. What is called *green laver* is *Ulva latissima*.

Laverna (Lat.). Among the Romans and Latins, Laverna was the patron goddess of thieves. A grove on the *Via Salaria* at Rome was sacred to her. The origin of the name is doubtful.

Law (Lat. lex). *Law, collective and particular.*—We employ the term *law* to denote a body of rules, or all the rules applicable to a given subject; e.g. the *Roman law*, the *law of nature*. We employ the term *a law* to denote an individual rule.

The idea of law, in its strictest sense, comprehends the notion of two parties; a superior imposing it, and an inferior obeying it.

Laws, improperly or metaphorically so called.—In common language it is usual to apply the word *law* to designate principles or properties which can only be thus named by analogy. Whenever certain causes invariably or generally produce like effects, this consequence of effect upon cause is popularly termed a *law*. Thus we speak of the *law of nature* with reference to inanimate or irrational subjects; of the *law of gravitation*, by which bodies are mutually attracted to each other; of the *laws of motion*, of the *laws* which regulate certain processes in animal and vegetable economy, &c. In this sense, laws have been defined to mean, 'the necessary relations resulting from the nature of things.' The analogy is nobly expounded in a well-known passage of Hooker's *Eccelesiastical Polity*, at the end of the first book.

Law defined.—Law, in its stricter sense, as applied to the voluntary actions of a man, comprises the notion of a command issued by a superior imposing an obligation on a subject.

Laws, Divine and Human.—Laws are divided, according to the superior who imposes them, into divine and human: the law of God, and the law of man.

Law of Nature.—The law of nature, however extensive in its philosophical meaning, is much more confined in that sense in which alone it is within the province of jurisprudence. Regarding it as merely applicable to the relative duties of men in a community, it is sufficient

LAW

for practical purposes to observe, with Grotius, that its first principle is the sociability of man; and, consequently, that the conservation of society in its actual state, whether from the motive of mutual distrust, as Hobbes maintained, or from innate benevolence, as his adversaries contended, is the duty which it imposes on everyone.

Let us suppose, therefore, that in a community such as our own there could occur at once a suspension of all civil positive law; and that, at the same time, the sanctions of the divine or unwritten law could be withdrawn. Men would thus be restored to a state of natural liberty. The natural law is that code of duties which would then take the place of all other legislation. Every act tending to injure our neighbour in person and property, every act in any way tending to disturb or impair the frame of society, would then be prohibited by natural law, as it now is prohibited by laws human and divine. Undoubtedly the natural law, in the sense in which it is commonly used, comprehends a far wider range of objects. The duties of personal holiness, the relative duties of the members of a family, the duties of active benevolence; all these are dictated to us by conscience, as much as abstinence from positive injustice. But the province of jurisprudence is too limited to admit of the consideration of these higher parts of morality, and is concerned only with political society.

Law of Nations.—The principle of natural law between individuals in a community would thus be the maintenance of the status quo, or actual condition of things, and the insuring to every one the continuance of all his possessions. This, therefore, is the elementary dogma of that only branch of natural law which can be said to exist as a definite rule of conduct; namely, the law of nations. Nations are in a state of natural liberty with reference to other nations. For, since they have no earthly superior to establish rules for them, the only maxims which govern their intercourse are certain conventional arrangements, the effect of which is the maintenance of the existing society and intercourse between the subjects of distinct sovereign states. All the rules of national law have this for their ultimate end. The natural law of men, to use the phrase of Hobbes, teaches the absolute duties subsisting between men and men; the natural law of nations, those subsisting between men in societies: or (in a compendious definition), national law is the law of nature applied to independent states as if they were individuals.

The law of nations, according to the comprehensive arrangement of Mackintosh, comprises 'the principles of national independence, the intercourse of nations in peace, the privileges of ambassadors and inferior ministers, the commerce of private subjects, the grounds of just war, the mutual duties of belligerent and neutral powers, the limits of lawful hostility, the rights of conquest, the faith to be observed in warfare, the force of an armistice, of safe-

conducts and of passports, the nature and obligation of alliances, the means of negotiation, the authority and interpretation of treaties of peace.'

But the law of nations, in its practical sense, widely differs from this extensive and philosophical compendium of international duties. Many of the maxims which relate to the subjects here enumerated belong rather to the higher province of morality than to that of jurisprudence. The only punishment of which the sanction can be applied in this species of law is the hostility of other states towards that which violates it. Whoever, therefore, is powerful enough, whether from his own strength or from position and alliances, to defy such punishment, is, in a certain sense, above the law. Hence, although the law of nations, considered as a branch of that of nature, would lay down absolute rules of conduct in the highest as well as the lowest matters of policy within its reach, it may safely be said that the law of nations as a body of recognised right extends only to a portion, and that the least important, of these matters. The only maxims which can be said to subsist as laws are those which are never or rarely violated by European states; because the inconvenience of their general neglect would overbalance the particular inconvenience of adhering to them in a given instance. Thus all will acknowledge that there is a wide difference, in point of preciseness and obligation, between the principles which forbid unjust aggression or severity towards the conquered, and those which prescribe the privileges of ambassadors and the protection of peaceful aliens.

The subjects to which national law is most strictly confined are customary rules respected by the mutual consent of nations, rarely infringed by the voluntary act of a sovereign power, and of which the infringement is considered to require satisfaction and reparation.

It is to be observed, that although several of the maxims of national law (such for example, as the sanctity of the persons of ambassadors) are usually held binding in transactions with all nations of the globe, yet the great bulk of its rules are only recognised and observed by the Christian states of Europe and America in their dealings with each other.

National law (from its defective sanction and want of a sovereign legislator as to its details) may, perhaps, be more properly termed the custom than the law of nations.

The reduction of the law of nations to a system was first made by Grotius, in a work which (as Sir J. Mackintosh has well observed), though we now indeed justly deem it imperfect, is among the most complete that the world has yet received, at so early a stage in the progress of any science, from the genius and learning of one man. To him succeeded Puffendorf; who, avoiding the inconvenient and unscientific method of Grotius, has (to use the words of the statesman already quoted), without the genius of his master, and with very inferior learning,

treated the subject with sound sense, with clear method, with extensive and accurate knowledge, and with a copiousness of detail sometimes indeed tedious, but always instructive and satisfactory. In addition to the works of these illustrious authors, the rules of national law are to be found, first, in the treatises of several other authors, who are usually regarded as authorities; of whom Bynkershoek (*Opera Omnia*, fol. Lug. Bat. 1767; Engl. trans. fol. 1749), Vattel, Wicqueshort, Rutherford (*Institutes* 1779), Von Martens, and others, may be cited: secondly, in the treatises which have been at different times concluded between European states; especially those of Westphalia, 1648; Utrecht, 1713; Aix-la-Chapelle, 1748; Paris, 1763; and Vienna, 1814. A full summary of the bibliography of this subject will be found in the introductory chapter of Mr. Manning's work on the *Law of Nations* (1839). (See also the standard work of Dr. Wheaton *On International Law*, 2 vols. 8vo., and the recent treatises of Sir R. Phillimore and Dr. Twiss.)

The language of conventions and treaties has frequently given occasion to disputes. Subsequently to the revival of letters, and until the peace of Nimeguen (1679), the state language ordinarily used was the Latin; but since that period it has chiefly given way to the French, which is now commonly used between nations employing different languages in their public acts.

Law, Positive or Municipal.—This is the term usually employed to distinguish law, in its ordinary sense (the expression of the will of a supreme power in a state), from all the other species of law (improperly so called) with which we have hitherto been occupied. It is called *positive* law, because established in the form of direct and definite injunctions; *municipal*, from the Latin *municipium*, a town possessed of privileges and local laws.

Positive law is 'a rule of civil conduct prescribed by the supreme power in a state.' Blackstone adds, 'commanding what is right, and prohibiting what is wrong.' But as it is clear that the right commanded and the wrong prohibited acquire the character of right and wrong only from being so commanded and prohibited, the latter half of the definition is evidently comprehended in the first. A regulation or body of regulations, usually adhered to by men in their dealings with each other, but not commanded by the civil power nor enforced by lawful punishment, is properly called a *custom*; but when such regulations, whether set by men to each other on a footing of equality, or by subordinate bodies within the state to individuals, can be enforced by lawful punishment, the sovereign power allowing such punishment, the sovereign power thereby adopts the regulations, and they become laws in the strictest sense of the word.

A law is also defined, 'a command of a political superior obliging the subject to a particular course of conduct.' This definition comprehends most of the civil institutions

with which jurisprudence is concerned; but it appears to exclude some which are nevertheless within the province of that science. For example—

1. Many laws are enacted to explain former laws, and also to repeal former laws. Neither of these can be said, in strictness, to answer the definition of law which describes it as a command, unless we consider them as re-enacting former commands. 2. The Roman jurists applied the term 'laws of imperfect obligation' to certain enactments of their law prescribing particular conduct, but without any penalty being expressed in the event of their violation. These were not commands, not being enforced, and could not be said to oblige the subject, who was at liberty to escape the obligation. Our laws recognise no such rules as these. If a statute enjoins or prohibits an action without adding any express penalty, the courts of justice *presume* that a violation of the statute is punishable. Law, as the subject matter of jurisprudence, is that which obliges the subject to a particular *course* of conduct by *general* rules of action. This excludes—

1. Laws made to permit or restrain the acts of specified individuals. Such were called by the Romans *privilegia*, or under the emperor's private rescripts; in our law, *private acts of parliament*. The sovereign body in the state, having the power to repeal and modify its own enactments, can by an expression of its will exempt particular persons from its own injunctions, or can impose new duties on particular persons. Such decrees have all the force of law; but they do not form a part of the general law of the country.

2. Laws made to suit a particular emergency, occasional or particular commands, which are distinguished from general laws by their *shorter duration*. To exemplify this difference, it has been said that should a sovereign command all his subjects to wear black as their ordinary dress, such a command would be a law; but should he order a general mourning for a stated time, such an order would not have sufficient permanence to entitle it to that appellation.

Every command given by a political superior is a law in point of force; but it is necessary to establish some distinction between occasional and general commands, as otherwise every direction of a public officer, every incidental command of a military superior, must be considered as a law. An act to suspend the collection of a duty for a given time, an order in council to admit bonded goods, or to issue any temporary regulations respecting trade and commerce, royal proclamations—all these are familiar instances of the species of occasional or particular commands.

Municipal law is commonly divided into two branches; that which concerns the public duties of individuals with reference to the state, and that which concerns the private relations of individuals towards each other. The division between these branches is not in all systems the same. Under the old Germanic institutions,

for example, most crimes were considered as civil injuries only.

Laws, strictly so called and forming the body of public right in each separate state, are to be found either in codes sanctioned by the authority of the state; or in decrees issued and made public by such authority; or, finally, in certain unwritten customs, to which that authority, by sanctioning them, has given the force of law.

The code of law, under all Mohammedan governments, is to be found wholly or in part in the Koran, which to Mohammedans bears the character both of revealed and civil law. Those of the Hindus and many other nations are likewise considered by them to possess the authority of a religious sanction.

In Western Europe the laws in force in most of its countries, although modified and republished by their several legislatures, are in great measure founded on what is termed the Roman law. This body of law is principally declared in the *Pandects*, *Code*, and *Institutes* of the emperor Justinian; but these contain only a digest of a small portion of the laws which prevailed in the ancient Roman empire.

The Roman Law.—'Inasmuch,' to use the words of our own learned judge Lord Holt, 'as the laws of all nations are doubtless raised out of the civil law, as all governments are sprung from the ruins of the Roman empire, it must be owned that the principles of our law are borrowed from the civil law, therefore grounded upon the same reason in many things.'—The manner in which the Roman law has been introduced into the jurisprudence of modern Europe may be said to have been twofold: first, through the prevalence of Roman usages, derived from the times of the empire, among the population of various countries, especially that part of it which was collected in towns; secondly, through the efforts of the ecclesiastics, who learnt the civil law from the *Codex* of Theodosius, and from the works of Justinian, and introduced it, as far as their authority extended, into such branches of justice as they were permitted to administer, and especially into their canon law, which the various princes of Europe permitted to be binding, to a different extent in different countries, upon their lay as well as clerical subjects. Thus the Roman law is in one sense the oldest and fundamental part of public right in many countries: in another sense it is a comparatively recent importation, altering the character of their respective legislations. The Roman law comprises what are termed the *INSTITUTES*, *PANDECTS*, *CODE*, and *NOVELLÆ* [see these terms]. These have been collected and published together, under the title of *Corpus Juris Civilis*; the best editions being those of Amsterdam (8vo. 1664) for the text, and of Gothofred (fol. Paris 1628) for the text and notes. The most elaborate modern work on the history of the Roman law is that of Savigny.

It would be impossible, within our limits, to give the reader any useful bibliographical

notice on a subject which in foreign countries has necessarily received such abundant attention and illustration; and English treatise writers on the civil law are few, and of no great value, that law having only existed among ourselves, as we have seen, in certain limited departments.

Civil Law in England.—In England, while in the way of ancient custom there are fewer vestiges of the civil law than in any other of the provinces of ancient Rome, yet in the way of ecclesiastical jurisdiction it has been wider spread and continued longer in force than almost anywhere else.

Although Britain was a highly civilised province possessing 140 cities and towns in the time of the Romans, yet the numbers and violence of her invaders, especially the Saxons and the Danes, appear to have extinguished almost every relic of her provincial customs and jurisprudence. It is chiefly, therefore, to the clergy that we are to look for the prevalence of the civil law in England, and it has been introduced by them in several ways.

1. At the Norman invasion a considerable accession to the numbers and influence of the spiritual body in England took place. A century afterwards the discovery of the *Pandects* rendered the study of jurisprudence familiar chiefly among that body, which monopolised most of the learning and intelligence of the age. The clergy introduced it into England; and, as the rude and simple justice of the Saxons was inadequate to meet the wants of the people, most of the early lawyers, who were themselves chiefly ecclesiastics, sought in the pages of their favourite works for principles to supply the defects as they arose. Hence in the works of Bracton, Britton, and Fleta (written expressly on the common law of England, that is the customary law of the Saxons modified by extensive introduction of Norman usages), we find constant reference not only in spirit but in words to the civil law. The time during which the study of the latter was most in vogue among English lawyers appears to have been between the reigns of Stephen and Edward III. During the greater part of that period a constant struggle was carried on between the ecclesiastical lawyers (supported in many cases by the crown) and the popular party in favour of the old customary right, which was defended by the temporal nobility. The final victory of the common law, and its establishment as the rule of the land, except in particular cases, may be dated from the reign of Edward I.

2. The jurisdiction of the lord chancellor of England is a subject considered elsewhere. [CHANCELLOR.] It is sufficient here to remark, that as most of the chancellors under the Plantagenet kings were ecclesiastics, and as the matters intrusted to their decision were those to which the rules of the common law did not apply, they generally searched for precedents in that of Rome; which has hence been largely imported into one great branch of modern English law, namely, *Equity*.

LAW

3. In some particular matters the rules of the civil law have always been allowed by custom to prevail in England. Of these, cognisance was taken by the courts of honour and chivalry, now fallen into disuse; by the High Court of Admiralty [ADMIRALTY]; and by the courts of the two universities of Oxford and Cambridge.

4. The chief influence of the civil law in England has been through the canon law, which was founded upon it.

Law, Canon.—The rules which were framed by the Christian church for its own spiritual polity may be supposed to have had their origin in the very earliest periods of Christianity itself; but all the authority and force which they possessed could arise only from the mutual consent of the faithful to be bound by them, until the establishment of Christianity as a state religion entirely altered the character of its spiritual constitution. The temporal jurisdiction which was then conceded to the bishops, together with the legal force given by several emperors, and by Justinian in particular, to the canons of councils, gradually called into existence a new and independent body of legislation.

When the Western Empire had been overthrown, the authority of the popes, as temporal governors, was by degrees confirmed in the city of Rome and the adjacent country. At the same time the power of the ecclesiastical body was increased and extended in other countries; and the reverence attached to their authority gave to the spiritual censures with which they visited particular offences a greater force than to the sanctions of the national law. Thus, besides matters of church government, which were at first the particular subject of the pontifical law, it comprehended within its purview numerous and important branches of the civil law of persons and property.

About the year 1150, the various edicts then in force of the several popes, together with the canons of councils, and the authoritative declarations of fathers and doctors of the church, were collected together by the monk Gratian, and reduced into a volume called the *Decretum*, and considered as the earliest authority in canon law.

In the next century, Pope Gregory IX. published five books of *DECRETALS* [which see], collected from the Decretal Epistles of the Popes, to which Boniface VIII. added a sixth book, about the end of the same century. To these were added, at subsequent periods, the Clementine Constitutions, a seventh Book of *Decretals*, and a Book of *Institutes*. The whole of these authorities were collated and published by Gregory XIII. in 1580, under the title of *Corpus Juris Canonici*.

In matters of evidence, and as far as practicable in the forms of proceeding, the compilers of the canon law founded their system upon that of Rome, with which they were best acquainted. In all such matters of civil jurisdiction as their legislation embraced, they

likewise assumed it as the basis of their structure. By the practice of all ecclesiastical courts the civil law is allowed to come in aid of and to supply the canon law, in all such cases as are there omitted. The subjects of the canon law were: 1. The hierarchy and government of the church; 2. All things relating to pious uses; 3. The wills of defuncts, the guardianship of orphans, and matters of marriage and divorce. But it was by no means permanently received, in most European countries, to its full extent. Its jurisdiction only subsisted by the toleration of princes; and therefore varied as the superstition or piety of these sovereigns, or their jealousy of ecclesiastical usurpation, alternately predominated. But, upon the whole, its authority became so deeply rooted, that even in countries which have in later times rejected the authority of the pope, its rules are still referred to, not merely in matters relating to church benefices, but also in some cases of purely civil jurisdiction.

Nevertheless, although in early times its authority was asserted by the popes on the ground of their temporal superiority over all earthly sovereigns, its force in every country must now be said to depend upon the will of the state, which gives the force of law to its provisions.

It is supposed that the decrees and canons of the church of Rome were adopted in this country so early as A.D. 605, shortly after the introduction of Christianity among the Saxons; but they were not fully recognised by the state until after the Norman conquest. From that period the power of the bishops made rapid strides, insomuch that they succeeded in retaining many branches of jurisdiction of which in other countries the temporal power had deprived them. In addition to the general canon law, we have in England a particular provincial law—the *constitutions* of the papal legates and councils of this country in 1237 and 1269; and a further body of constitutions, framed in provincial synods under the authority of successive archbishops of Canterbury, from Stephen Langton in 1222 to Archbishop Chichele in 1414, and adopted subsequently by the province of York. These constitutions have been illustrated by the commentaries of distinguished ecclesiastics, and principally those of Lyndwood, who flourished in the reigns of Henry V. and Henry VI. The canons of the Protestant church passed in the convocation of A.D. 1603, although ratified by King James I. for himself and his successors, yet do not (as Lord Mansfield finally decided) bind the laity, except so far as they declare the older provisions of the law. The most standard work on English Ecclesiastical Law is Gibson's *Codex Juris Anglicani*. The best guides for the student are the compilations of Dr. Burn and Sir R. Phillimore.

Law of England, Common Law.—This expression is used in two different senses, according to the subject under consideration. We speak of the common law in contradistinction

to the civil law, or to equity; meaning a certain portion of our laws relating to a definite subject matter, and administered in courts following particular rules of evidence and modes of procedure. We also, by the common law, sometimes mean the unwritten or ancient customary law; in this sense it is opposed to the statute law, which is of positive enactment.

The constitution and laws of our Anglo-Saxon ancestors have been the subject of innumerable theories and contradictory systems, since the ingenuity of modern times has been applied to their investigation; but all the efforts of the learned have gone no further than to establish the existence of a few principles and customs common, for the most part, to the Germanic tribes in general.

Edward the Confessor reduced the customs of the country into something resembling a system of law; and although his enactments are lost, it is to his reign that we must look for the most authentic form of Anglo-Saxon polity. The king was guided and controlled in his deliberations by the *witan*, or chief men, assembled in the *gemote*, or meeting; but their relative power and that of the sovereign varied according to the strength or weakness of the latter. Justice was administered in the county courts, where the *good men* or landowners assembled, and the bishop and sheriff presided. Questions of property were decided by ordeal, or by a tribunal of sworn witnesses. In criminal as well as in civil cases the defendant sometimes freed himself by the oath of compurgators, or *wager of law*, as it was called when adopted by the Normans. The inhabitants of every district were mutual guarantees, by the custom of frankpledge, which was founded on two principles: the one, the liability of the lord or superior for the appearance of his vassals; the other, the collective responsibility of the tithing, or hundred, for all its individual members: which was not prevalent in all England, and entirely unknown in the northern shires.

By the Norman conquest and the division of the better portion of England between Norman proprietors holding in chief of the crown, the feudal system of law, as regarded land and its incidents, was early introduced into the country. Other portions of Norman jurisprudence were imported at a later period, through the medium of the king's courts; which, being at first confined in jurisdiction to the domains of the crown, gradually supplanted the old Saxon courts, although these long continued to be governed by their national law.

The three great institutions in which English law differs from that of other countries—the parliament; the system of tenures and their incidents, on which the law of real property is founded; and the trial by jury—may perhaps be said to have been founded on Norman jurisprudence, but to have become prevalent through their analogy to Anglo-Saxon institutions. [PARLIAMENT.]

The first consequence of the invasion of the Normans was, that different modes of trial

were prevalent, according to the nation to which the contending parties belonged. Compurgation or '*wager of law*' was the common mode of decision between Englishmen. In criminal cases, it was usually by the oath of eleven compurgators chosen out of an array of fourteen. In civil suits, the amount of the compurgation required seems to have been regulated by the value of the property claimed. To this peculiarly English mode of trial was added the *wager of battle*, which is first named in the laws of the Conqueror, but which either French or English and French might use. *Inquest of witnesses* was a Norman mode of trial in civil cases, by which witnesses were summoned from the neighbourhood in which the quarrel arose to declare on their oath the truth concerning the matter in question. Finally, the ancient proof of *ordeal* subsisted in criminal cases.

This diversity in the modes of trial was accompanied by a diversity of judicature. The ancient county courts received one blow by the withdrawal of the bishops, who ceased to preside in them, being chiefly foreigners, and who gradually established a separate jurisdiction of their own. A still more important wound, in its consequences, was inflicted by the increasing power and influence of the king's courts (at first only confined to causes arising within the royal demesne), in which the Norman law and modes of procedure were adopted, and in which the machine of our own common law was gradually elaborated by judicial ingenuity during successive centuries.

Henry II. is commonly regarded as the founder of the common law. His principal contribution towards it consisted in his ordinance of the grand assize; justices in eyre, or circuit. Justices of the king's courts, being appointed to try causes by inquest of twenty-four witnesses, at the option of the tenant or demandant, if either party preferred to purchase this mode of trial instead of the ordinary trial by battle. Shortly after his reign the Fourth Council of Lateran, by abolishing the ordeal (A. D. 1215), gave a new impulse to the development of the jury system. Criminal cases were now tried by a jury of witnesses *de vicineto*; and the process by which these witnesses, both in civil and criminal cases, became converted into sworn judges of the fact, has never been distinctly traced; but the intermediate steps had certainly all been passed before the reign of Edward III., possibly before the death of the first monarch of that name.

If Henry II. was the founder, Edward I. may almost be regarded as the completer of the common law. From his time to the present no change has taken place in its general principles: all that subsequent reforms have effected has been to accommodate those principles to altered circumstances. And long may the spirit of these institutions remain unchanged amidst the march of improvement; holding together, as they now do, the mightiest commercial community of the globe, with no less beneficial authority than they exercised six hundred years

ago over the barons, vassals, and burghers of a small feudal by!

The system of real property may be said to have been fixed by the statute *Quia Emptores*, 18 Edw. I. Before that time we may consider the lands of England as having been subject, in general, to the unrestricted feudal law. All land was held, mediately or immediately, of the king. The two classes of free proprietors were those who held by the military service (of Norman introduction), and those who held by the old English custom, their property in their lands being retained by them, subject only to acknowledgement or fealty to the sovereign—a less honourable, but probably a less burdensome tenure. But either of these tenants might, in his turn, create fresh tenants under him, yielding the same homage to him which he yielded to the sovereign. Below these, the only two classes of tenants recognized by the law were those who held of the king, or mesne lords, by pure villenage, or absolute and base service; and by villen socage, which was also a base service, but restricted to certain specified duties. From the tenure of pure villenage have sprung our present copyhold tenures; by which certain lands are held within manors (which are the old estates held in early times directly of the king) by the will of the lord, as it is expressed in their grant, although by long usage the will of the lord is merely nominal, and the obligations of the tenant consist only in certain specified rents and services.

The object of the statute *Quia Emptores* was to restrain the creation of fresh subordinate estates, by declaring that if anyone alienated his land by sale or feoffment (which purported to convey it in perpetuity) the feoffee should hold the same, not of the feoffor, but of the feoffor's lord, whether a mesne lord or the king himself. Hence all manors must have existed prior to the reign of Edward I.; as it is essential that there should be in them tenants who hold of the lord, and such tenancies could not have been created at a later period.

When alienation of lands and tenements was made in early Norman times, the alienation was either to the donee and his heirs for ever—thus giving him an absolute unrestricted property, descendible to his heirs, whether male or female, subject only to his homage to the donor; in other words, a *fee simple*; or it was upon condition—as, for instance, a grant to a donee, provided he had issue; under which grant, if the donee died without issue, or his issue came to fail, the land would revert to the donor. The conditional donees had devised, with the assistance of the king's judges, various ingenious methods of defeating these provisions; as by aliening as soon as they had issue, and then repurchasing the fee simple. It was to fix the law of conditional gifts that the statute *De Donis*, 13 Edw. I., was passed; by which such a donee was absolutely prevented from aliening the tenements. Hence arose *estates in fee tail*: in other words, estates granted to a man and to certain specified heirs; for example, the heirs

male of his body. In after times, when the restraint on alienation which this statute created began to be repugnant to the more liberal feelings of the people, certain devices were invented (*uses and reversions*), whereby the donee in tail was enabled to bar the entail and acquire the fee simple, as he could have done before this statute was passed.

Besides these famous statutes, we find the reign of Edward I. distinguished by the confirmation of *Magna Charta* and the *Charter of Forests*. The first of these great constitutional acts contains few provisions of much importance in legal history, and was far more valuable as an evidence of the spirit of the country in restraining arbitrary usurpations, than, as is commonly supposed, by establishing any new franchises, or even confirming ancient ones. Perhaps its most important legal effect was the fixing to the city of Westminster the Court of Common Pleas, which had formerly caused the suitors much inconvenience by following the person of the king in his various progresses.

It is also to the reign of Edward I. that we must refer for the distinct definition of the province of that court, and of the other two superior common law courts of record, the King's Bench and Exchequer. The history of these three courts is far too intricate, and requires too much explanatory statement, to find a place in these pages. It must suffice to observe, that the King's Bench is the ancient *Aula Regia*, in which the king was supposed, as by fiction of law he still is, to sit in person, and which followed him in all his progresses, inasmuch that in the reign of Edward I. it actually sat in Scotland. [KING'S BENCH.] The Court of Common Pleas, or Common Bench, had in strictness jurisdiction in all civil causes between subject and subject. In this court only real actions, in which the right to land is tried—now almost all abolished [REAL ACTION], but anciently the most important part of judicial business—could be adjudicated. The Court of Exchequer was intended to recover the king's debts and ordinary revenues of the crown. It acquired in process of time a jurisdiction over common personal actions, by the fiction of the complaining party being a debtor to the king; and also an equitable jurisdiction, similar in form to that of the chancellor's court.

The equitable jurisdiction of the chancellor had probably begun long before the reign of Edward I. [CHANCELLOR], and before his reign the original writs, by which actions were commenced, had been sued out or obtained in the chancery, the clerks of which, like the pontifical framers of the *actiones* among the Romans, had the monopoly of drawing up these magical instruments. In the reign of Edward I. (by Statute of Westminster the Second, 13 Edw. I.) an important change was made in this branch of law, by authorising the clerks to frame writs adapted to particular cases which the old forms did not adequately suit. Hence originate our modern actions of *trespass on the case*.

From the same statute the modern judges of *assize* and *nisi prius* [Nisi Prius] are chiefly derived. These were originally occasional commissioners sent down into the counties to deliver the gaol of prisoners, or to try civil causes. By this statute the commission was first directed to be given to the king's justices, associated (as they still are in form) with one or two discreet knights of the county. The commission of assize is, strictly speaking, a commission to try disputes respecting land wherein the writ of assize (which dates, as before stated, from Henry II.) was brought—now fallen into disuse. The commission of *nisi prius* originates in what may now be called a legal fiction. When the pleadings in an action in the superior courts [PLEADING] are concluded, and an *issue of fact* is taken between the parties, the issue is appointed, by the entry on the *record* or written proceedings, to be tried by a jury from the county in which the proceedings arise, at Westminster, *unless before* the day appointed (*nisi prius*) the judges shall have come to the county in question. Besides these commissions, the same judges try criminal cases by virtue of a *commission of the peace*, in which they are associated with the justices of the county; a commission of *oyer and terminer*, to hear and determine all treasons, felonies, and misdemeanours; and a commission of general gaol delivery, to try and deliver every prisoner who shall be in the gaol at their arrival in the county.

Having referred to the reign of Edward I. as the period under which a general sketch of our old common law might be most advantageously presented, we proceed to notice very briefly the chief alterations which mark its subsequent history. These alterations can be easily ascertained where they were caused by the highest legal authority—by the parliament of the nation. But far greater changes have been wrought by the silent course of the tribunals—by the discretionary power which our judges have assumed to extend the remedies, which they were authorised to administer, to cases unprovided for by earlier law, which either the ingenuity of practitioners, or, in many more instances, the increasing wants and more intricate relations of life, had called into existence. To trace such alterations is as impossible as to note, day by day, the increase of stature by which the child grows into the man. Often, in laboriously investigating the history of our English jurisprudence, we are surprised when we look back, after perusing the events of a generation or a century, to the state of things as it existed at the beginning of that epoch, and find that although we cannot with all our diligence detect in its history the occurrence of any external changes in the subject on which our minds are fixed, yet the same forms, the same modes and circumstances, present themselves to our eyes under a totally different aspect and character.

The reigns of Henry II. and Henry III. are principally remarkable for the gradual substi-

tution of the king's justices of the peace for the various elective magistrates who exercised the several duties of that office before. It was in the reign of the latter prince also that the parliament is supposed to have finally acquired its present form. Under the successors of the Edwards, and during the wars of the fifteenth century, small accessions were made to the general bulk of English law; but during those times very great changes were silently taking place in the disposition of property by means of the invention of Uses, borrowed from the civil law. This extensive and most important subject will be found briefly treated of under the head of CHANCELLOR.

The laws of Henry VII. had principally in view the benefit of his exchequer. Under his successor, whose reign forms so important an epoch in political history, the laws of property were very considerably modified by the two statutes of Uses and of Wills. [For the former, see USE.] The latter rendered general the power of devising estates by will. The system of bankrupt laws also had its commencement under Henry VIII. His daughter Elizabeth did not add much to the essential and valuable parts of our statute book; but under her government the Acts which restrained the alienation of lands by ecclesiastical bodies were passed, and also the celebrated statute respecting the poor, of which the policy forms, even at the present day, a subject of some controversy. In the succeeding century, the reign of James I. witnessed the first attempt to limit the period at which actions and suits might be commenced; and the first statute of bankruptcy. But it is most remarkable for the laborious attempt to systematise our ancient law by Sir E. Coke, one of the most acute if not philosophical jurists of any age or country. That of Charles II. forms the next marked epoch in the history of our law, after those of Edward I. and Henry VIII. His restoration was distinguished by the abolition of feudal tenures and incidents, and the reduction of all the modes by which estates of inheritance might be held (with few exceptions) to two only, freehold and copyhold. The Statute of Frauds, a necessary protection, perhaps, to unwary transactors of business, but a source of endless litigation; the statute which regulates the distribution of the effects of intestates; and finally, the celebrated Habeas Corpus Act, which gave, or rather confirmed, to every person imprisoned by any authority short of the express and definite course of justice, the means of releasing himself—are all productions of this reign.

The eighteenth century, while it gave rise to new views and widely extended discussions on jurisprudence, did not in England produce much substantial alteration by statutory enactment. It was rather a period of preparation for change, in the political as well as the legal world, than of actual reform. But it was distinguished by the learning and acuteness of several judges who occupied the seats of justice during many years, and introduced by the slow

exertion of their own authority a new spirit into institutions of which the forms were preserved.

But the present century has been emphatically a period of legal reform: and some at least of the great changes effected may be studied under the heads **LAW**, **CRIMINAL**; **PLEADING**; **ECCLIESIASTICAL COURTS**; **BANKRUPTCY**; and so forth.*

The term *common law* is ordinarily employed in two different senses. In its legal signification it expresses the old unwritten law, established by precedent and custom; comprising, it has been said, 'all recognised doctrines and customs, however introduced, which are neither to be found in the statute book, nor depend on the adjudication of courts of equity.' For this floating mass of legal principles our ordinary sources are precedents, or decisions of common law judges, as contained in published reports. Where these fail us, reference may sometimes be had to more uncertain guides, the dicta of legal writers, or the general principle and tendency of our laws, for authority in deciding a particular dispute.

In its popular sense, common law is opposed to equity and ecclesiastical law; and thus comprises the whole of that law, both criminal and civil, which is administered in courts having trial by jury, and all the other subjects which are within the purview of the common law courts of Westminster Hall, and of the various local jurisdictions of the country (except so far as some of them exercise equitable authority). It has been defined to be 'the whole of that code, whether founded on statute, usage, or precedent, which is now administered in the common law courts of Westminster Hall;' and this definition will comprehend the law administered in the various local courts in question, as these are bound to act on the decisions of the superior courts. Its peculiar characteristic is, that questions of fact arising out of its proceedings are submitted to the decision of a jury.

It is, perhaps, not very easy to assign either the history or the theoretical principles of the separation of equity from common law. The former was undoubtedly in the first instance a jurisdiction of a remedial character, intended to moderate, according to the conscience of the judge, the rigour of legal judgments; but this is a peculiarity which can scarcely be said to distinguish it in the present day. Its rules are as accurately laid down by precedents as those of the common law itself; but there are some subjects (as trusts) which, having been created in frustration of the provisions of the common law, are out of its cognisance. Over these courts of equity have an *exclusive* jurisdiction. There are others over which both equity and law have *concurrent* jurisdiction. But the remedies applied by law to injuries committed are subject to certain inflexible rules. The power of a jury has limits from the very nature of the institution. It can award a debt sought to be recovered, or damages for an injury; but it cannot modify the remedy according to

peculiar circumstances. Nor has it any means to enforce a course of action other than by assessing damages for neglecting it. To take an familiar instance: If A sues B at law for breach of covenant, and judgment passes in favour of A, all that a jury can do is to award damages to A for the breach of contract; but equity can, by a process of its own, compel B to a specific performance of the contract under the penalties attached to a contempt of court. So, if one of several joint contractors be liable, at law, for penalties or debts incurred in respect of their joint undertaking, his only legal remedy is by an action against each; in equity, he can compel each of his partners to contribute to the extent of their liability.

Law, Criminal, of England. Some account of various portions of this important and extensive subject will be found under the appropriate headings throughout this Dictionary. But the extensive consolidation of the criminal law effected by the Acts of Parliament of 1861 (24 & 25 Vict.) renders a brief synoptical view of it more attainable than before that time it could have been.

Offences are punishable by **INDICTMENT** or **INFORMATION** [which see], or, in minor cases, under many Acts of Parliament, by summary conviction.

For the distinction between **FELONIES** and **MISDEMEANOURS**, see those heads respectively.

The mode of compelling appearance is by summons or warrant (now regulated by 11 & 12 Vict. c. 42); the latter being granted, in the first instance, in felony, and in many misdemeanours.

The party accused being arrested under the warrant (or bailed where bail is admitted), or having appeared to the summons, is charged by indictment before the grand jury. [JURY.] The grand jury having found a true bill against him, at assizes or sessions, the prisoner is put to the bar to answer it, which is termed *arraignment*. If he is at this time not of sane mind, the jury, on finding him so, may cause his commitment for safe custody at the pleasure of the crown. If otherwise, he answers the indictment either by demurring to it as bad in law, or by pleading. The result of a successful demurrer is that the indictment is *quashed*; but this, since the modern improvements in the law, is of rare occurrence. Pleading may also be in *abatement* or to the *jurisdiction*, raising issues of law, but these are also now almost reduced to nullities. Pardon, and former acquittal or conviction of the same offence, may also be pleaded. But the ordinary plea is *guilty* or *not guilty*; and on the latter, the issue of the prisoner's guilt being raised, the trial proceeds before the jury; as to the ordinary incidents of which, see **JURY**.

Offences are now ordinarily divided as follows:

1. Against the queen and her government.
2. Larceny and other cognate offences (embezzlement, burglary, &c.), the law as to which is consolidated by the Larceny Act, 1861.
3. Malicious Injuries to Property (Act, 1861).

4. Cheats, Frauds, and Forgeries (Forgery Act, 1861). 5. Offences relating to the coin (Coinage Offences Act, 1861). 6. Offences against the person (Act, 1861). To which may be added various classes of misdemeanours and offences not embraced by the statutes of that session; offences against public justice; perjury, conspiracy, and extortion; offences against the public peace, religion, and morals; against public trade (now nearly obsolete); against the public revenue; nuisances; and the like. (See the arrangement in Woolrych's *Criminal Law*, as amended by the statutes of 1861.)

The affirmation or denial by the jury of the guilt of the prisoner is termed their *verdict*. The many technical modes of escape for a prisoner, which formerly existed from imperfect or irregular verdicts, have now been nearly got rid of by the enactments that, on a trial for felony or misdemeanour, the jury may in all cases find the prisoner guilty of an *attempt*, if they are not satisfied that the offence was fully committed; and that, if on trial for a misdemeanour the party shall appear to have been guilty of a felony, he shall not be entitled to acquittal.

The effect of acquittal is to discharge the prisoner of all future charges in respect of the same offence.

The verdict of *guilty*, having been given, may be impeached by a motion to arrest the judgment, for errors of law on the face of the record. In misdemeanours, not in felonies, except in some special cases, a new trial may also be obtained on ground of miscarriage at the former trial. If the verdict be unimpeached, conviction and judgment follow. The punishments now in force for offences are: fine; corporal punishment in a few cases; imprisonment; PENAL SERVITUDE; TRANSPORTATION [see those two arts.]; and death. The profuse employment of capital punishment was the opprobrium of the English code, even down to the commencement of the present century. It is now confined to cases of high treason and murder.

By the Act 11 & 12 Vict. c. 78 (1849), criminal courts throughout the country were authorised to reserve any question of law which might arise on the trial (in the event of conviction) for the judgment of a criminal appeal court, composed of the judges of the superior courts at Westminster, or five of them at the least, who may affirm, reverse, or amend the judgment.

Law, Grimm's. In Comparative Philology. [LANGUAGE.]

Law, Maritime. [MARITIME LAW.]

Law, Martial. This phrase, which has no definite legal meaning, is used to express the suspension of ordinary, and the substitution of arbitrary, tribunals for the trial of criminal and (if need be) civil cases, by the authority of the crown, sanctioned by statute, in emergencies of rebellion, invasion, or insurrection. It is usually carried out by putting under the cognisance of courts martial a great variety of sub-

jects which by ordinary military law do not appertain to them, to be tried in a summary way. The statute for putting into execution martial law usually gives a power to arrest and detain in custody all suspected persons, and to cause them to be brought to trial in a summary manner by courts martial, and to execute the sentence of all such courts, whether of death or otherwise; and declares, that no act done in consequence of these powers shall be questioned in any of the king's ordinary courts of law, and that all who act under the statute shall be responsible for their conduct only to such courts martial.

Law, Military. This term denotes properly that law which is administered by courts martial to soldiers, under the authority of parliament and the Mutiny Act, annually passed, together with the Articles of War. (Simmons *On Courts Martial*; Papon's *Manual of Military Law*.) [COURTS MARTIAL.]

Laws of Chemical Combination. [EQUIVALENTS, CHEMICAL.]

Laws of Gaseous Diffusion. [GASES, DIFFUSION OF.]

Laws of the Twelve Tables. [DECEMVIRI.]

Lawn (Fr. *linon*). A fine variety of cambric, formerly exclusively manufactured in Flanders. Of late the lawn manufacture of Scotland and of the north of Ireland has been brought to rival that of the Flemish weavers.

LAWN (apparently the same as Dutch *laen*, Fris. *lana*, Welsh *llan*). In Gardening, a surface of grass or turf in pleasure grounds kept smoothly mown.

Lawsonia (after Dr. Isaac Lawson). A genus of *Lythraceae*, yielding the famous Henna of the East. The plant *L. alba*, sometimes called *L. inermis*, is a dwarf shrub with privet-like leaves, which in the powdered state are used as cosmetics throughout the East, for dyeing the finger and toe nails, the tips of the fingers, the palms of the hands, and the soles of the feet, to which it imparts a reddish orange colour, considered by women as greatly enhancing their beauty. The men use it for colouring their beards. When used, the powder is made up into a pasty mass, and spread on the part to be coloured.

Laxatives (Lat. *laxativus*, from *laxare*, to loosen). Gentle aperient medicines, opposed to cathartics, which are drastic purgatives. Laxatives merely evacuate the contents of the intestines without occasioning any general excitement, or even stimulating the exhalant vessels of the canal. [CATHARTIC.]

Lay (Prov. *lais*, A.-Sax. *lioth*, Ger. *lied*). The lyric poems of the old French minstrels, or *trouvères*, were termed *lais*; but the title in modern usage is given to narrative poems of moderate length in simple style and light metre.

LAY. In Agriculture. [LEA.]

Lay Brothers. Persons received into convents of monks, under the three vows, but not in holy orders. The introduction of this

LAY ELDERS

class of devotees appears to have begun in the eleventh century. They are dressed somewhat differently from the other monks or *brothers of the choir*, and often employed in the manual exercises necessary for the uses of the community. The Carthusian and Cistercian orders are said to have first recognised the distinction, and their example was followed by the other orders. The same distinction exists in monasteries of females between the nuns properly so called and the lay sisters, or sisters converse.

Lay Elders. In Presbyterian churches, ministers with ecclesiastical jurisdiction, not ordained as clergymen, who assist the pastor in each congregation. [PRESBYTERIANS; KIRK.] The divines of that persuasion rest the appointment of lay elders in some measure on that of presbyters 'in every city' by Paul and Barnabas, who, they imagine, from the manner in which they are mentioned, could not have been all preachers. (Hooker, *Ecc. Pol.* b. vi.)

Laying. In Gardening, a mode of propagating plants by laying down shoots, and covering a portion of them with soil, so that the extremity of the shoot is left above ground, and the shoot itself not detached from the plant. In order to facilitate the rooting of such shoots, called *layers*, the portion buried in the soil is fractured by twisting or bruising, or cut with a knife immediately under a bud. This operation, by obstructing the return of the sap from the leaves, occasions its accumulation at the wounded part, when roots are there produced from the effort of nature to perpetuate life.

Laying. In Architecture, the first coat, on lath, of plasterer's two-coat work, the surface of which is made rough by sweeping it with a broom, to form a key for the next coat; the difference between the laying and the rendering coats being, that the latter is the first that is applied on a brick or other wall.

Laying Off. In Shipbuilding, this term denotes the developing in thin wood, on the mould loft floor, from the construction drawings, a section (actual size) of any part of the timbers of an intended ship.

Laying a Piece of Ordnance. In Gunnery, pointing a piece of ordnance so that the projectile may strike the required object. [GUNNERY.]

Layman (Gr. *laikos*; from *laos*, *people*). The appellation by which the rest of the community are distinguished from the clergy or the members of a profession, as of medicine, the bar, &c. [LAITY.]

Layman, or lay-figure, among painters signifies a small statue, whose joints are so formed that it may be put into any attitude for the purpose of adjusting the drapery of figures.

Lazar House or Lazaretto (Ital.). A public building in the southern European states, of the nature of an hospital, for the reception of the poor and of persons afflicted with contagious disorders. In some places lazarettos are set apart for the performance of quarantine; in which case only those are admitted who have

LE ROI LE VEUT

arrived from countries infested by the plague, or suspected of being so. Howard's well-known account of the principal lazarettos of Europe furnishes the most detailed and interesting particulars of these establishments.

Lazarists. In Ecclesiastical History, a body of missionaries founded by St. Vincent de Paul in 1632; so termed from occupying the priory of St. Lazarus, at Paris, as their head-quarters. Their primary object was to dispense religious instruction and assistance among the poorer inhabitants of the rural districts of France. They were dispersed at the time of the Revolution, but have been since re-established.

Lazarus, St., Order of. A military order of religious persons, originally an association of knights, for the purpose of maintaining lepers, &c. in lazaret-houses or hospitals, especially in the Holy Land. Being driven out of Palestine in 1263, they followed St. Louis to France. In 1490, their order was suppressed by Pope Innocent VIII., and united with that of St. John; but the bull was not universally received. In 1672, they were united in Italy with the order of St. Maurice; in 1603, in France, with that of Our Lady of Mount Carmel. The knights of these united orders were allowed to marry.

Lazulite (Arab. *azul*, *heaven*, and Gr. *lithos*, *stone*). The name applied by Haüy and some other mineralogists to LAPIS LAZULI [which see]. By Werner, Dana, and others, the term is applied to a hydrous phosphate of alumina and magnesia from Styria and the Tyrol. It generally occurs granular or massive of various shades of azure-blue, inclining to green or white, and is distinguished from Lapis Lazuli by never being accompanied by Iron Pyrites.

Lazzaroni (Ital.). A name given to the poorer classes at Naples, from the Hospital of St. Lazarus, which served as a refuge for the destitute in that city. Forty years ago two large sections of the people were generally comprehended under this name—the fishermen, and the lazzaroni properly so called, who lived in the streets, and performed no labour but that of errand porters and occasional servants. These alone were estimated at 40,000, and formed a powerful community, which under Masaniello accomplished the revolution of Naples, and, in later times, overthrew the popular government, under the influence of Cardinal Ruffo and the English party. But during the French occupation of Naples they ceased to exist as a distinct class; and the name is now only used to designate in general language the mob or populace of that city.

Le Roi le veut (Fr. *the king wills it*). A form of words by which the royal assent is intimated by the clerk of parliament to the passing of public bills. To private bills the royal assent is expressed by *Soit fait comme il est désiré*. The dissent of the sovereign to the passing of any measure is signified by the words *Le roi s'avisera*. [PARLIAMENT.]

LEA

In Agriculture, a term applied to lands which are kept under grass or pasturage for a short period. For example, in a rotation of fallow, wheat, clover and rye grass, for three years. The ground, when under clover and rye grass, is said to be in lea.

Lead (Dutch lood). A metal of a bluish-grey colour, known from the earliest ages: the alchemists gave it the name and symbol of Saturn ♄ . Its specific gravity is 11.38. It is soft, flexible, and inelastic; and though ductile and malleable, is possessed of little tenacity. It fuses at about 600° ; and if air be carefully excluded, it does not appear to be volatile at a white heat. When melted in open vessels, it soon changes into a grey powder, which upon further exposure to heat and air becomes yellow, and is called *massicot*; or, when partially fused, so as to assume a scaly form, *litharge*. If massicot be heated, and stirred to prevent fusion, it gradually absorbs oxygen, acquires a red colour, and is called *red lead*. When red lead is heated in nitric acid, it is partly dissolved, and partly converted into a brown powder, which is insoluble, and is a *peroxide of lead*. Massicot, or the yellow oxide of lead, is the *protoxide* (PbO), and that which forms the salts of this metal: it is constituted of 1 atom of lead = 104, and 1 of oxygen = 8, and its equivalent is 112. The brown peroxide consists of 1 atom of lead and 2 of oxygen (PbO_2); and red lead is intermediate between the two extremes, consisting probably of an indefinite mixture of the two oxides. The protoxide of lead is soluble in the greater number of the acids, and forms a variety of salts; of these the carbonate and the acetate are the most important. *Carbonate of lead* (PbO, CO_2), or, as it is commonly called, *white lead*, is the basis of white oil paint, and consequently of a number of other colours: it may be prepared by exposing sheet lead to the fumes of vinegar, by which it is gradually corroded, and its surface becomes covered with an incrustation, which, when scraped off and well levigated, is white lead. [CERUSE; WHITE LEAD.] This article is also made by precipitating a solution of acetate of lead by carbonate of soda; it consists of 112 oxide of lead and 22 carbonic acid. *Acetate of lead* ($\text{PbO}, \text{C}_4\text{H}_2\text{O}_5$) is made by dissolving carbonate of lead in acetic acid, for which purpose the pyroligneous vinegar is chiefly used. It crystallises in six-sided prisms, but is generally met with in confused crystalline masses. It is soluble in about 4 parts of cold water, and the solution has a remarkably sweet taste; whence the term *sugar of lead*, usually applied to this salt. It consists of 112 oxide of lead and 51 acetic acid. The crystals include 3 atoms of water, and are therefore represented by the equivalent 190; or 163 dry acetate and 27 water. When protoxide of lead is boiled in distilled vinegar, or in a solution of acetate of lead, a dense solution of *sabacetate* or *triacetate* of lead is obtained: it is not easily crystallisable. This solution is often used in the

LEAD FOR SOUNDING

chemical laboratory as a test and precipitant: and it forms the *extract of lead* (*Goulard's extract*) of pharmacy.

The most important native combination, or *ore of lead*, is the *sulphide*, composed of 104 lead and 16 sulphur. It is the *galena* of mineralogists, and from it the commercial demands for lead are supplied: it is roasted to expel sulphur, and the lead thus oxidised is reduced by heating with charcoal. [GALENA.]

The action of water upon lead is curious and interesting, in consequence of the universal use of leaden water pipes, and of water cisterns lined with this metal. Perfectly pure water, such as distilled water, put into a clean leaden vessel and exposed to air, soon corrodes it, and delicate tests discover oxide of lead in solution in the water; but river and spring water exert no such solvent power: the carbonates and sulphates in such water, though in very minute quantities, prevent the action. Hence it is that leaden cisterns are used with comparative impunity for the preservation of common water, and that the crust which forms upon the metal prevents further action. As this crust partly consists of carbonate of lead, which is very poisonous, great care should be taken to prevent its *diffusion* through the water upon any occasion, as by scraping or cleaning the cistern. Leaden cisterns also sometimes prove injurious in consequence of galvanic action, where iron or zinc pipes are soldered or let into them: the lead is thus rendered electro-negative, alkaline matter is evolved upon it, and small quantities of the oxide or carbonate are thus rendered soluble. There are several re-agents by which very minute quantities of lead may be detected. Among these, solution of sulphuretted hydrogen is perhaps the most effective: it produces a brown tint in water containing the minutest trace of lead, and it similarly discolours the greater number of the insoluble salts of the metal. A solution of sulphate of soda is also a sensible test of the presence of dissolved oxide of lead; it forms a white cloud in water, containing the smallest traces of it: a fragment of iodide of potassium dropped into such water presently occasions in it a yellow tint, in consequence of the formation of an iodide of lead.

Lead, Black. [PLUMBAGO.]

Lead Glance. Native sulphide of lead. [GALENA.]

Lead of a Slide Valve. The small space which is left open at the end of each stroke of the piston, on the opposite side of the movement, to admit the steam, for the purpose of checking the speed of the piston, and of facilitating the opening of the valve for the reverse motion.

Lead for Sounding. The common hand lead weighs from 7 to 11 lbs., and is used with about 20 fathoms of line. The leadsman stands somewhere on the side of the vessel, usually in the channels; lets the lead descend near the water; then, swinging it over his head once, or twice if the ship is going fast, throws it forward. The line is marked at 5, 7, 10, 13, 17, and 20

LEAD SPAR

fathoms. The numbers between are called *deeps*, or more properly *déps*; the meaning being that in the absence of a mark the lead-man estimates by the dip of the line; thus, by the mark 7, by the deep 9, indicates 7 and 9 fathoms.

When the depth is great, the deep-sea lead of 25 to 30 lbs. is used, with a much longer line marked at every 10 fathoms. The lead is dropped from the fore part of the vessel, being thrown as far as possible in the line of the ship's drift. To make the sounding fairly vertical, it is desirable to heave the ship to...

Lead Spar. Native carbonate of lead. [CHAUSE.]

Leads or Space Lines. Pieces of type metal cast to specific thicknesses and lengths, lower than types, so that they do not make any impression in printing, but leave a white space where placed. Their general use is to be placed between the lines when a work is not closely printed (this being considered to look better than when printed solid), and also to branch out the heads of pages and titles.

Leadere. [NEWSPAPERS.]

Leadhillite. Native sulphate and carbonate of lead, found crystallised with other ores of lead at Leadhills in Scotland.

Leading Note. In Music, the sharp seventh of the scale, so called because it naturally leads to the key-note.

Leading Wind. A Nautical term for a full fair wind.

Leaf (Ger. laub). In Botany, an expansion of the bark at the base of a leaf-bud, prior to which it is developed, its functions being at once those of respiration, digestion, and nutrition. It is a plate of parenchyma, through which spiral vessels and woody tissue ramify. Its surface is covered with stomates, which communicate with minute hollow chambers in the interior. It is in the leaf that most of the peculiar secretions of a plant are prepared out of the crude sap which the roots obtain from the soil.

Leaf-buds. In Botany, rudiments of young branches, made up of scales imbricated over each other, the outermost being the hardest and thickest, and surrounding a minute axis, which is in direct communication with the woody and cellular tissue of the stem. When stimulated by light and heat they extend into branches; or if artificially removed from the plant that bears them, they are capable of multiplying the individual from which they have been taken.

Leaflet. In Botany, a small leaf formed by the petiole of a leaf branching out, and separating the cellular tissue of the lamina into more than one distinct portion, each of which forms a perfect lamina of itself.

League (Low Lat. *leuca*; Fr. *lieue*: Mr. Wedgwood connects the word with Gael. *leug*, *leug*, a stone, as used to mark the distances between places). A measure of length, used in reckoning distances by sea. The sea league is three nautical or geographical miles, or the one-

LEAKAGE

twentieth of a degree, and consequently about 3.45 English miles.

The common land league is a well-known itinerary measure on the continent of Europe, chiefly in France. The French, however, have two distinct leagues: the legal posting league (*lieue de poste*), containing 2,000 toises, and equal to 3.42 English miles; and a league of 25 to the degree (anciently the *lieue moyenne*), or equal to about 2.76 English miles. It is supposed that the league, or *leuca*, was introduced into England by the Normans, where at an early period it came to be reckoned as equivalent to two miles of the time; this being the sense in which the term *leuca* is used by the oldest law writers, and in most of the old English charters. [MILL.]

League (Fr. *ligue*, Ital. *legua*, from Lat. *ligare*, to bind). In Politics, a league appears to be in strictness an alliance between two or more powers, in order to execute some common enterprise. It is, therefore, more active and less durable than an alliance or a confederacy; both of which have some permanent object, while neither necessarily requires active co-operation. In the middle ages, the word *league* was used nearly in the sense now attached to these latter terms; hence we read of the Hanseatic League, and of the three leagues once subsisting in the canton of the Grisons in Switzerland; both of which were more properly confederacies.

League, The Holy, or simply The League. In French History, a political association formed by the Roman Catholic party in France under the reign of Henry III. The project of the League is said to have been framed by one David, an advocate; or, rather, he first conceived the idea of uniting the separate associations of the Catholic party in the provinces into one great confederacy. His written scheme bears date 1576. It was received with eagerness, especially by the municipality and citizens of Paris and other large towns. The object of the League was at first only the overthrow of the Protestant power: but the princes of the house of Guise soon placed themselves at its head, and the leaders of the party were not slow in adopting the project of changing the succession, and placing the duke of Guise on the throne. In 1588, the citizens, under the impulse of the League, drove Henry III. from Paris on the Day of the Barricades, and formed the revolutionary government of 'the Sixteen.' But after the death both of the duke and the king, much division arose in the head-quarters of the League at Paris as to the choice of a successor; and in 1591 the popular party, or that of the Sixteen, was put down by the citizens: which event in effect destroyed the power of this great association, although it still continued to exist, even after the abjuration of Henry IV.

League, Solemn. [COVENANT.]

Leakage (Dutch *lekken*, to drip; the same root is found in the Latin *liquare*, to filter). In Commerce, an allowance in the

LEAN-TO

customs granted to importers of wine for the waste and damage which the goods are supposed to receive by keeping.

Lean-to. In Architecture, a building whose rafters pitch against or lean on another building.

Leap-year or Bissextile. A year containing 366 days. In the Gregorian calendar this occurs every fourth year, excepting years which complete centuries; in which case the intercalary day is omitted, unless the number of the year is divisible by four. [CALENDAR.]

Lease (akin to Fr. *laisser*, Ger. *lassen*, *to let*).

In Law, a lease is properly a conveyance of lands and tenements (usually in consideration of rent or other annual recompense), made for life, for years, or at will, but always for a less time than the lessor or party letting has in the premises. The usual words of operation are, 'demise, grant, and to farm let.' The conveyance by a lessee of part of his interest is properly an underlease; of the whole, an assignment.

Lease and Release. In Law, a mode of conveyance appropriate to freehold estates, arising out of the ancient principles of the law of real property, whereby a release was the appropriate instrument to vest the freehold in one already in possession under a lease. It was generally adopted in conveyancing as the most convenient mode of transfer, but is now dispensed with by recent enactments, particularly 8 & 9 Vict. c. 106 s. 2.

Least Squares, Method of. [MINIMUM SQUARES.]

Leather (Ger. *leder*, Welsh *lledr*). The prepared skins of animals. The principal object of the art of converting skin into leather is to render it strong and tough, durable, and often waterproof, and to prevent its destruction by putrefaction. The skins are first cleansed of hair and cuticle, and then impregnated either with vegetable tan, as in the production of what is called *tanned* leather, or with alum and other salts, as for *tawed* leather; these processes are sometimes combined, and tanned leather often undergoes the further operation of *currying*, or impregnation with oil. As instances of these different results, thick sole leather is tanned; white kid for gloves is tawed; the upper leather for boots and shoes is tanned and curried; fine Turkey leather is tanned with summac.

A skin does not consist of gelatine, as hitherto supposed, for gelatine is soluble in water, and a hide or skin is not. What was supposed to be gelatine is an isomeric substance named *ossein*. In the usual method of tanning, ossein passes into gelatine by a slow putrefactive process, and this combines with the tannin. To render tanning a quicker process, some method is wanted of converting ossein rapidly into gelatine.

Tanned Leather.—For thin skins which are afterwards curried, the hide is cleansed, and soaked for a day or two in water; it is then *beamed*, or stretched upon a half-cylinder of wood, where it is cleared of adhering fat and flesh; it is then soaked for several days in a pit

LEATHER

of lime and water, by which the hair and cuticle are so far loosened as to admit of being scraped off upon the beam; the hide is then washed and put into the *grainer* pit, which is a mixture of water and dung—that of hens, pigeons, or dogs being preferred. When the hide has here become soft and supple, it is again thoroughly cleaned, and submitted to the tanning liquor, which is at first used very weak, and gradually strengthened till the operation is complete: this requires from two to four months for calf skins, and from ten to twelve months for ox hides, with oak bark, but a much less time if gambia is used; and the latter hides, instead of being limed and dunged, are generally, after having been cleaned in water, placed in heaps, where they begin to putrefy, and then the hair may be removed without lime, which would be apt to render the skin hard and harsh. The further opening of the texture, so as to prepare it for tanning, is effected by immersion in a sour liquor of fermented rye or barley, or in weak sulphuric acid. This process is called *raising*, and immediately precedes the tanning. When fully tanned, the goods are drained, stretched upon a convex piece of wood called a *horse*, and beaten and smoothed; or the leather is sometimes passed between cylinders to make it more solid and supple: it is lastly dried, by suspension in an airy covered building. It will be obvious [TAN; GELATINE] that the principal change effected in this process depends upon the combination of the gelatine of the skin with the tannin of the oak bark, or other astringent material which is used, and that great care is requisite to insure the perfect penetration of the hide (especially where it is thick) by the tanning material: hence the necessity of using weak liquors at first, and gradually increasing their strength; for if the hide were in the first instance put into a strong infusion of bark, the exterior surfaces would become so perfectly tanned as to be impervious to the further action of the liquor, and the centre would remain untanned, and consequently soluble and putrescible; so that we judge of the completion of the process by the leather, when cut through, being of a uniform brown throughout, anything like a white streak in the centre announcing the imperfection just mentioned.

Tanned Sheep Leather, &c.—The skins are first soaked for a few hours in a water pit, then well washed and painted with milk of lime on the flesh side, and hung in a warm room till the wool readily pulls off; they are then scraped, and soaked for some weeks in lime water, which checks the putrefaction and hardens the texture; the skin is then again beamed, smoothed, and trimmed, and put into a vat of bran and water, where it is kept for some weeks in a state of gentle fermentation, and becomes thin and extensible, and fit for any subsequent operation: in this state it is called a *pelt*. The pelt is placed in a lime pit for two or three weeks, according to the season of the year, then fleshed and trimmed

LEATHER

on a beam; if intended for skiver leather, the pelt is split into two parts, the grain side for leather, and the flesh side for parchment or chamois. For the first branch, the grain has to be pressed in a grainer, to remove all lime, hair, and cuticle; then placed in a drench, made of bran and water, for twelve hours; after which it is ready for tanning in shumac. For tawed leather, the pelt is not split; the preparing process is the same, but the tanning is done with alum and salt. The method of bringing kid and calf skin to the state of pelt is nearly the same as for lamb skin, except that liming is used before the hair is taken off, which is only sold to plasterers, whereas lambs' wool is more valuable, and would be injured by the lime. If the pelts are to be tawed, they are worked about in a solution of alum and salt in warm water, which again makes them thick and tough; they are then washed and again fermented in bran and water till the thickening is reduced by the removal of some of the salts; lastly, they are stretched on hooks, and dried in a stove room, when they become a tough flexible white leather; but to give them gloss and suppleness they are again soaked in water, and trodden in a large pail or rolled in a drum containing the yolks of eggs beaten up with water; they are next dried in a loft, smoothed with a warm iron, and afterwards softened on a stake, when they are dyed with various colours for gloves and ladies' boots.

Morocco leather, as it is called, is chiefly prepared from goat skins, which after the action of lime water are brought down by a dung bath, and reduced to the state of pelt. If intended to be dyed red, they are sown up in the form of a sack, with the grain side outward, and immersed in a warm cochineal bath; the sack is then tanned in a bath of sumach: the skins intended to be blacked are sumached without any previous dyeing. The graining and polishing are effected as follows: The skins are stretched upon a smooth inclined board, and rubbed over with a little oil to supple them. Those intended for black leather are previously brushed over with a solution of iron; they are then rubbed over with a glass ball cut into a polygonal surface, which polishes them, and makes them firm and compact; lastly, the grained surface is given by rubbing the leather with grooved boxwood rollers fitted to a machine, called a *jigger*, suspended from the ceiling. *Curried leather* is tanned, and then softened by soaking in water and rubbing; it is pared with a broad sharp knife, the edge of which is turned over so as to be at right angles to the plane of the blade; the leather is next rubbed with a polished stone, and while still wet besmeared with fish oil, or a mixture of this with tallow. As it dries, the oil gradually penetrates in proportion as the moisture evaporates. The grain side is blackened by iron liquor for the uppers of ladies' shoes, but the flesh side with lampblack and oil for the uppers of men's boots and shoes.

Shammy leather is generally sheep or doe

LECTICA

skin, prepared as already mentioned by dressing, liming, &c., and dyed if necessary, and then finished in oil. *Russia leather* acquires its peculiar odour from an empyreumatic oil from the bark of the birch tree. (There is an excellent abstract of the manufacture of different kinds of leather in Aikin's *Dictionary of Chemistry*, from which much of the above is abridged.)

American leather cloth, or *panonia leather*, is an artificial compound variously prepared. In one example, a textile fabric is impregnated with oak bark and gelatine for forming leather, and stearic acid and an alkali for forming a kind of insoluble soap. A flexible varnish containing lampblack is afterwards added.

The leather manufacture of Great Britain is of great importance, being inferior in point of value and extent only to those of cotton, wool, and iron.

The number of persons engaged in all the various branches of the manufacture in Great Britain is estimated at between 300,000 and 400,000, and the entire value of the manufacture at more than 20,000,000*l.* sterling, the leather for boots and shoes alone being valued at about 12,000,000*l.* Leather was long subject to a duty, which necessarily placed the manufacture under the surveillance of the excise; but the duty was totally abolished in 1830, and the manufacture is now relieved from every sort of trammel and restraint. (*Com. Dict.*)

Leaven (Fr. *levain*, from Lat. *levare*, to raise). A piece of sour dough used to ferment and render light a much greater quantity of dough or paste. By the Mosaic law leaven was forbidden during the Passover; hence St. Paul speaks of keeping the Paschal feast with the unleavened bread of sincerity and truth. Figuratively, the word is applied to anything which gradually but surely affects the moral or intellectual character of man, whether for good or for evil.

Lecanora (Gr. *λεκανωρα*, a basin). A genus of Crustaceous Lichens. *L. tartarica* is the Cudbear of commerce; and some have supposed the manna of the Israelites to be *L. esculenta* and *affinis*, which in Armenia and Algeria are blown about and heaped by winds, and in times of scarcity ground up with corn.

Lecanoric Acid. A colourless crystalline body contained in the *Lecanora* lichen.

Lecca Gum. The gum of the olive-tree, collected abundantly at Lecca in Calabria.

Lecanite. A hydrated sulphate of soda and ammonia found in the cave of Las Piedras in Honduras, by Dr. le Conte, who considers it to be formed from the decomposed excrements of bats, large numbers of which have probably inhabited the cave for ages.

Lectern. A desk, or support for a book, for the use of readers in churches or other public places. The support is frequently made by the wings of an eagle, carved in wood or bronze. Many rich specimens of mediæval lecterns are found in churches in this country.

Lectica (Lat.). A sort of couch or litter,

used by the Romans, of two kinds, the one for carrying living persons, the other for bearing dead bodies to the funeral pile. The bearers were called *lecticarii*.

Lectisternium (Lat. from *lectus*, a couch, and *sternere*, to spread). A religious festival or ceremony among the ancient Romans, celebrated during times of public calamity, when the gods themselves were invited to the entertainment; their statues were taken from their pedestals, and laid on couches. The first festival of this sort, according to Livy (v. 13), was held in the year of Rome 364 (on the occasion of a contagious disease which committed frightful ravages among the cattle), and lasted for eight successive days. On the celebration of this festival, enemies were said to forget their animosity, and all prisoners were liberated.

Lector (Lat. a reader). In the early Church, a person set apart for the purpose of reading parts of the Bible and other writings of a religious character to the people. They were consecrated by prayers and ceremonies for this office, and in the third century appear to have been proper officers of the church. It is probably from this institution that the order of preachers in parish churches in England called *lecturers* is derived, who hold a distinct office from the vicar, rector, or other ecclesiastical functionaries; they are chosen by the vestry or chief inhabitants of the parish, supported by voluntary subscriptions and legacies, and usually officiate on Sunday afternoon. (Hook's *Church Dictionary*, art. 'Lecturer.')

Lecture. This word signifies generally a discourse read by a professor to his pupils; but it is applied in a more extended sense to every species of instruction communicated *viva voce*. In the Scotch and Continental universities, as well as in those recently established in England, the great business of teaching is carried on by means of public lectures, delivered at stated periods, and embracing every subject included in the curriculum of study; but at the two great English universities, the college tutors bear a principal part in the work of instruction. Still, within the last few years the professorial system has been made much more efficient, and has acquired more general importance.

Public lectures have been adopted from the earliest ages as a convenient mode of teaching the elements of every branch of human knowledge; and if they be properly compiled, and accompanied by strict and regular examinations, few means seem better calculated to awaken the attention of the student, to abridge his labours, and to guide his enquiries.

Lecythidaceæ (Lecythis, one of the genera). A natural order of epigynous Exogens belonging to the Myrtal alliance of Lindley, and known by their dotless leaves, polypetalous flowers, their indefinite stamens collected into a fleshy hood, and their many-celled ovary. They are large trees, with showy flowers, found in the hottest parts of South America, and comprise the Cannon-ball tree, *Couroupita guianensis*; the Sapucaja *Lecythis Zabucajo*, and the *Bertholletia*

esoclea, which furnishes the Brazil-nuts of the shops.

Lecythis (Gr. *λήκυθος*, an oil jar). A genus of South American trees of large size, representing the order *Lecythidaceæ*. They furnish some of the nuts of commerce. Thus, under the name of Sapucaja nuts, the seeds of *L. Zabucajo* are commonly sold in our fruit shops, and they will probably take the place of the closely allied Brazil nuts, to which they are greatly superior in point of flavour and digestibility. They are rather more than two inches long and one wide, covered with a longitudinally furrowed corky shell, and grow in large hard woody fruits, shaped like urns, measuring about six inches in diameter, and having close-fitting lids at the top. Our supply comes from Pará, and is principally the produce of the Brazilian forests.

L. ollaria is another species producing large fruits, commonly known as Monkey Pots, but its seeds are not so palatable as those of the last, having a bitter flavour.

Ledererite. A variety of Gmelinite found at Cape Blomidon in Nova Scotia, and named after the Baron L. von Lederer.

Lederite. A massive variety of Sphene, found at Grenville in Canada, and distinguished as a sub-species on account of its peculiar cleavages.

Ledger. [BOOK-KEEPING.]

Ledgers. In Architecture, the horizontal pieces of timber used in scaffolding; they lie parallel to the wall opposite to which they are erected.

Ledger-line. In Music, a line either above or below the staff, when that is not sufficient in extent to lay the notes upon. It is above the staff in ascending progressions, and in descending progressions below it.

Ledges. On Shipboard, intermediate supports for the decks. They run across from side to side between and parallel to the beams, but are much thinner.

Ledum (Gr. *λήδων*). The plant called Labrador Tea is *Ledum palustre*, a low shrub of the Ericaceous order.

Lee, Leeward. Sea terms, denoting generally the side or quarter not directly exposed to the wind. The *lee side* of a ship is the opposite to that on which the wind blows when it crosses her course, and which is termed the *weather side*. *Leeward* is on the *lee side*; opposed to *windward*, or on the *weather side*. A *lee shore* is the shore on the *lee side* of the ship, or the shore on which the wind tends to blow her; and a ship is said to be under the *lee* of the shore when the wind blows from the shore, or when she is in some measure sheltered by the shore. The names *Leeward* and *Windward*, as applied to the West India Islands, were given to them from their situation in a voyage from the ports of Spain to Cartagena or Portobello. The islands which lie to leeward extend from Porto Rico to Demerara.

Lee-board. A flat width of planking, which being let down perpendicularly into the water on the lee side of flat-bottomed vessels,

serves as a temporary keel, and opposes the action of the wind to drive them to leeward.

In the American *centre-board* boats, than which no craft can sail nearer to the wind, there is a deep lee-board working in a water-tight groove in the centre of the boat.

Lee-gage. This term implies the having a position farther to leeward than some other given object.

Lee-way. In Navigation, the deviation of the course actually run by a ship from the course steered upon; or it is the angle formed between the line of the ship's keel and the line which she actually describes through the water. In consequence of the action of the wind or currents, a ship is generally impelled *sideways* as well as forward, whence the direction of her motion is different from that of the keel. Suppose the whole force urging the ship to be resolved into two—one producing the motion

A B in the direction of the keel, and the other the motion A C in the

same time at right angles to the former; then the ship will move in the direction of the diagonal A D, and the angle D A B is the *lee-way*. To obviate the effects of this lateral motion, the ship is laid on a course to the windward of the point to which she is bound.

All needless top-hamper, as a poop or raised fore-castle, increases the tendency to lee-way.

Leech (Goth. *leikeis*, *lekeis*, perhaps akin to Gr. *λεῖχω*, Eng. *lick*). This name is given to those abranched red-blooded worms, or annelids, which are provided with a sucker at both ends of the body [*Hirudo*], and of which we possess a few native species; some frequenting the fresh waters, as the horse leeches (*Hæmopsis sanguisorba* and *H. stagnorum*); others inhabiting the ocean, where they are parasitic upon fishes, as the skate-sucker (*Pontobdella muricata*). The medicinal leech (*Sanguisuga medicinalis*) belongs to that subdivision of the family *Hirudinidae* which is characterised by having the superior lip of the anterior cup or sucker divided into several segments, and the oral aperture transverse, triradiate, and surrounded by three cartilaginous jaws, each armed with two rows of very fine teeth. This apparatus enables the leech to penetrate the skin so as to insure a ready flow of blood without causing a dangerous wound. The upper lip is marked with ten small points considered as eyes. The species of the genus *Sanguisuga*, viz. *S. officinalis* and *S. medicinalis*, are most common in the south of France, whence great numbers are exported to this country. The leech-dealers of Bretagne drive horses and cows into the ponds, that the leeches may fatten and propagate more abundantly by sucking their blood. Children are employed to catch them by the hand; and grown persons wade into the shallow waters in the spring of the year, and catch the leeches that adhere to their naked legs. They are also taken by a sort of net made of twigs and rushes, which is used in the summer when the leeches retire into the deeper waters.

The best method of preserving these valuable little animals is stated by the author of the article 'Leech' in the *Penny Cyclopædia* to be that described by Fée. It is as follows:—

Into a marble or stone trough a layer of seven inches of a mixture of moss, turf, and charcoal is to be put, and some small pebbles placed above it; at one extremity of the trough, and midway between the bottom and the top, place a thin plate of marble pierced with numerous small holes, upon which there should rest a stratum of moss, or portions of the *Equisetum palustre*, or horse-tail, firmly compressed by a layer of pebbles. The trough is to be filled with water only so high that the moss and pebbles should be but slightly moistened. A cloth is to be kept over the mouth of the trough. This is imitating as nearly as possible their natural condition; and the charcoal not only aids in keeping the water sweet, but appears to prevent the leeches being attacked by parasitic animals, to which they are very liable. The water should be changed about once a week, and more frequently in warm weather.

The great importance of ascertaining the best method of preserving the medicinal leech may be inferred from the extent to which the trade is carried on, and the consequent increasing scarcity of these indispensable adjuncts to medicine. Four only of the principal dealers in London import 7,200,000 annually.

Leeches of a Sail. The side edges of a sail. *Leech-lines* are small ropes from the middle of the leeches of a sail to blocks on its yard on the opposite sides of the mast; when hauled, they brail up the sail and rapidly diminish its area.

Leedsite. A mechanical mixture of the sulphates of lime and baryta found in a carboniferous rock between Leeds and Harrogate in Yorkshire.

Leefange. An iron bar across a ship's deck for the sheet of a fore-and-aft sail to slip on during tacking.

Leek (A.-Sax. *leac*). The *Allium Porrum* of botanists. [*ALLIUM*.]

Leelite. A silicate of alumina coloured of a deep flesh-red by a small percentage of manganese. It occurs compact and massive, with a peculiar wax-like texture, and a lustre and translucency like that of horn, at Gryphyttan in Sweden. It was named after Dr. J. F. Lee of Cambridge, and is the Hellefinta of the Swedes.

Leet (A.-Sax. *leod*; Ger. *leute*, *people*). The court leet, or view of frankpledge, was an ancient Anglo-Saxon institution answering a double purpose: 1. The administration of justice in the trial of offences and the abatement of nuisances; 2. The preservation of the peace, and the prevention of crime, by the reception and enrollment of the pledge which each man was obliged to give by becoming a member of some tything. The possession of a court leet was the characteristic of the hundred, of which the proper leet was distinct from, and subordinate to, that which was held by the sheriff

LEGACY

on his tourn. The court leet of the hundred was usually held by a bailiff or steward of the sheriff; but it was sometimes granted, as well as the leet of a smaller jurisdiction, to private lords. A court leet also properly belonged to a borough, which ranked as a hundred; but such private and borough leets were, like the leet of the hundred, subordinate to the county leet of the tourn.

Legacy (Lat. *lego*, *I bequeath*). A gift by will of personal property, as goods and chattels; a testamentary gift of real property being called a *devise*. Legacies are general, such as a gift of a sum of money out of the general estate of the deceased; or specific, as a gift of a particular bank note or coin, or of any other individual chattel, as a horse or a jewel; or residuary, as a gift of the residue of the estate remaining after all the debts of the deceased and general and specific legacies have been satisfied. General legacies are subject to an equal rateable abatement, if the estate is not sufficient for payment of them in full; but a specific legacy is not subject to abatement, unless it be necessary for the payment of debts. A specific legacy is, however, subject to what is called *ademption*, which is the consequence of the subject-matter of the legacy being one identical thing in specie: thus, if a testator bequeath a particular horse, which he afterwards disposes of in his lifetime, the legacy is said to be adeemed, or taken away, because the horse bequeathed has no longer any existence as part of his property, and the legatee will not be entitled to another horse of the testator's in lieu of it. This identity of corpus is so inherent in the notion of a specific legacy, that if 100*l*. in consols were bequeathed, and the same sum were afterwards transferred by the testator to another stock, the transfer of itself would adeem the legacy. The mode of compelling executors to pay a legacy is by suit in equity for the administration of the testator's assets: courts of common law have not, in general, any jurisdiction over such matters. Executors cannot be compelled to pay a legacy until the expiration of a year after the testator's death: they are allowed that period for ascertaining and discharging his debts; and even after a legacy has been paid, the legatee must refund if it should be necessary for the payment of creditors who come in, although after the period above mentioned. The party to whom a legacy is bequeathed is termed *legatee*. [WILLS.]

Legate (Lat. *legatus*). A high functionary, in general a cardinal or bishop, whom the pope sends as ambassador to the courts of foreign powers. Legates are—1. A *Latere*, who possess the highest degree of authority, these only being commissioned by the pope to take his place in councils; 2. *De Latere*; 3. Legates by office are such as enjoy the titular distinction of legate by virtue of their dignity and rank in the church, but have no special mission.

Legation. [AMBASSADOR; DIPLOMACY.]

Legato (Ital. *tiel*). In Music, a term used to denote the tying one note to another, which

LEGENDTRE'S SYMBOL

is done by placing these marks \sim \frown above or below the notes intended to be so joined. The legato mark placed over a series of notes indicates that they are to be played smoothly, as if the sounds were bound together. The word applied as a general direction for a piece intimates that it is to be performed in a smooth style.

Legatura. In Music. [DIVINE NOTES.]

Legatus (Lat.). In Roman History, legati were of two kinds: 1. Ambassadors, corresponding to those of modern times; 2. Legates, who accompanied the proconsuls and praetors into their provinces, or aided the general in the management of his army. Legates of this last-named class varied in number according to the requirements of the service in which they were engaged; and legates of the former class governed provinces in the absence of the proconsul or praetor, sometimes without any mention of the officer whose deputies they were.

Legend (Lat. *legenda*, *things to be read*). A book originally used at divine service. In it were recorded the lives of saints and martyrs, portions of which were selected and read for the edification of the people. These legends were studiously perused in the refectories of cloisters, and were earnestly recommended to the perusal of the laity, as so many evidences of the truth of the Roman Catholic faith. Among these the *Golden Legend* (the work of Jacobus de Voragine, archbishop of Genoa in the thirteenth century), which is a collection of the lives of the saints, maintained its ground in the church for two hundred years. But although many of the legends consist of tasteless and unmeaning fictions, many are of a highly poetical and striking character, and throw much light on the diffusion of myths. There are some sensible remarks as to the value of the early Christian legends in Beugnot, *Histoire de la Destruction du Paganisme en Occident*, i. 280. In a general sense, the term *legend* is used to denote any fictitious or doubtful narrative; such as the exploits of heroes of the middle ages, or the history of a people or district in which truth is so mixed with fable as to be inseparable from it. [MYTHOLOGY.]

Legend. In Numismatics, that which is written round the field of a medal; opposed to *inscription*, which is written across it. [NUMISMATICS.]

Legendre's Symbol. In the theory of numbers, a symbol employed in investigating the quadratic character of any positive or negative number A which is prime to a prime number p . It was first introduced by Legendre in his *Essai sur la Théorie des Nombres*, Paris 1798; is

written thus $\left(\frac{A}{p}\right)$; and has the value 1 or -1 according as A is a quadratic residue or not. It may, therefore, be defined by the congruence

$$A^{\frac{p-1}{2}} \equiv \left(\frac{A}{p}\right) \pmod{p};$$

LEGENDRE'S SYMBOL

for if A be a quadratic residuo, we have

$$x^2 \equiv A,$$

and hence, by FERMAT'S THEOREM,

$$x^{p-1} \equiv A^{\frac{p-1}{2}} \equiv 1 \pmod{p}.$$

It may easily be shown that if A , when resolved into its prime factors, has the value

$$= a_1^{a_1} a_2^{a_2} \dots a_m^{a_m},$$

$$\left(\frac{A}{p}\right) = \left(\frac{a_1}{p}\right)^{a_1} \left(\frac{a_2}{p}\right)^{a_2} \dots \left(\frac{a_m}{p}\right)^{a_m};$$

so that in investigating the quadratic character of A , it is only necessary to examine those of its prime factors which appear with odd exponents. It may further be shown that

$$\left(\frac{-1}{p}\right) = (-1)^{\frac{p-1}{2}},$$

that

$$\left(\frac{2}{p}\right) = (-1)^{\frac{p^2-1}{8}},$$

and that, if p and q are odd primes (not both negative)

$$\left(\frac{p}{q}\right) \left(\frac{q}{p}\right) = (-1)^{\frac{1}{2}(p-1)(q-1)}.$$

The last equation is the expression of one of the most important and beautiful laws in the science of arithmetic. It is known as *Legendre's law of reciprocity*, having been first enunciated by that geometer in the *Histoire de l'Académie des Sciences* for 1785. Gauss appears to have arrived independently at the same law, and was incontestably the first to publish a rigorous demonstration of it. Gauss, indeed, has given us no less than six demonstrations of this law, all more or less subtle and, without exception, most valuable contributions to science. It would, in fact, be difficult to estimate too highly the many advantages to mathematical science which have resulted from the numerous demonstrations which have been given of this simple law, pronounced by Gauss himself to be 'the gem of the higher arithmetic.' The following enunciation is given by Prof. Smith in his admirable 'Report on the Theory of Numbers' (*Proceedings of British Association*, 1859), which the reader desirous of further information will do well to consult. 'If p and q be two primes, the quadratic character of p in regard to q is the same as that of q with respect to p , unless p and q have each the form $4n+3$, when their quadratic characters are opposite.'

Jacobi, in 1837 (see also Crelle's *Journal*, vol. xxx.), communicated to the Academy of Berlin the following extension of Legendre's

notation and law. The symbol $\left(\frac{A}{P}\right)$, where P is a product of the equal or unequal uneven primes p_1, p_2, p_3 , &c., being defined by the equation

$$\left(\frac{A}{P}\right) = \left(\frac{A}{p_1}\right) \left(\frac{A}{p_2}\right) \left(\frac{A}{p_3}\right) \dots$$

LEGION

and Q being any other uneven number prime to P ,

$$\left(\frac{P}{Q}\right) = (-1)^{\frac{1}{2}(P-1)(Q-1)} \left(\frac{Q}{P}\right).$$

Legerdemain (Fr. *light of hand*). A term given to some deceptive or sleight-of-hand performances, which depend either entirely on dexterity and address, or derive but a small degree of aid from philosophical principles. [MAGIC.]

Leggiadro (Ital.). In Music, a direction to the performer that the music to which the word is appended is to be performed gaily or briskly.

Legion (Lat. *legio*). A division of the Roman army, comprising ten cohorts, thirty maniples, or sixty centuries; so that if there had always been one hundred men in each century, as its name imports, the legion would have consisted of six thousand men. But the number was, in fact, variable.

There were usually three hundred cavalry joined to each legion, which were divided into ten troops (*turmæ*), and each of these troops into three bodies of ten men (*decuriæ*). The defensive arms of the legionaries were an oblong shield, a helmet, hauberk, and greaves; their offensive weapons were a sword and two long javelins. The legion was drawn up in three lines; the soldiers in each of which were distinguished by the names *Hastati*, *Principes*, and *Triarii*. The *Hastati*, who formed the first line, were young men in the flower of life, and originally used long spears, which were, however, afterwards discarded. The *Principes* occupied the second line, and were also men in the prime of life. The *Triarii* were veteran soldiers, and formed the third line. In each legion there were six military tribunes, who commanded under the consul, each in his turn, usually for about a month. This was the early organisation of the legion, as it is known to us chiefly from the description of Livy, at the time of the great Latin war in the fifth century of the Republic. It was materially changed in later times, and the three original lines were discarded, probably about the time of the Punic war. But it always retained its distinctive character of a separate army, provided with its complement of cavalry and light infantry; and it has been remarked, as a striking proof of the military genius of the Romans, that after so many ages of additional experience, recent captains, and particularly Napoleon, have found it advantageous to divide their armies into separate corps, each in a similar manner complete, with its own cavalry and artillery; and these, in the French armies, usually averaged from 4,000 to 6,000 men, or about the number of a Roman legion. The organisation of the legion is explained in most works on Roman antiquities, but has been nowhere so thoroughly treated as by M. L. Beau, in a long series of memoirs which appeared from time to time in the *Mém. de l'Acad. des Inscriptions et Belles Lettres*. (See particularly vols. xxxv. xxxvii. xxxix.; also Smith's

LEGION OF HONOUR

Dictionary of Greek and Roman Antiquities, s.v. 'Exercitus.')

Legion of Honour. An order instituted by Napoleon I., when first consul of France, for merit, both military and civil. The order consisted, under the Empire, of grand crosses, grand officers, commanders, officers, and legionaries. They were divided into sixteen cohorts, each of 407 members; but the total number was afterwards much increased. Pensions, from 250 to 5,000 francs per annum, were attached to these distinctions. After the restoration of Louis XVIII. the order underwent some modifications in its constitution, and its members were reduced to a smaller scale. But among the first acts of the present emperor was the reconstitution of this celebrated order on an extended basis. This was effected by the law of April 19, 1862. The legion now consists (beginning with the lowest grade) of knights, who may in four years become officers, of whom there are 4,000. After two years these may be promoted to commanders, of whom there are 1,000; grand officers, 500, after an interval of three years; grand crosses, 80, after five years. But in all cases a campaign (or rather a campaign year) counts for two years. The highest functionary is the grand chancellor.

Legislation. [Law.]

Legislature. The name given to the body or bodies in a state in whom is vested the power of making laws. Thus the King, Lords, and Commons of Great Britain, whose united consent is indispensable to the framing of a law, are styled *the legislature*.

Legitimacy (Lat. *legitimus*, *lawful*). In Jurisprudence, the state of a child born in lawful wedlock.

LEGITIMACY. In Politics, this term signifies, in its strictest sense, the accordance of an action or of an institution with the municipal law of the land. The principle of obedience to civil authority, in whatever hands the law has placed it, is consecrated by religion as well as by sound philosophy. Resistance to, or evasion of, the legal commands of a superior, is thus an offence against the law of God as well as of man, in things in themselves indifferent as well as in things commanded by the principles of morality. How far they must be obeyed when against the conscience of the subject, is one of those questions of casuistry which never can receive a solution applicable to all cases and circumstances. In this sense it is clear that the attribute of legitimacy belongs to no particular form of government, but is equally inherent in all when lawfully established. But, looking at the subject from a higher point of view, the question arises, when and how shall a government be taken to be lawfully established? This can only be directly answered by two classes of political philosophers. The first attribute the quality of legitimacy only to hereditary monarchical government, which they conceive to be peculiarly of divine appointment, deriving it from the patriarchal form of society. This theory has the advan-

LEGITIMACY
